\*As of May 1, 2003, chapter <81> Microbial Limit Tests will be replaced by <81> Microbiological Examination of Nonsterile Products: Microbial Enumeration Tests, and the new chapter <82> Microbiological Examination of Nonsterile Products: Microbiological Attributes of Nonsterile Pharmaceutical Products. Chapter <1111> Microbiological Attributes of Nonsterile Pharmaceutical Products—Acceptance Criteria for Pharmaceutical Preparations and Substances for Pharmaceutical Use will become official. Also on May 1, 2003, Chapter <1111> Microbiological Attributes of Nonsterile Pharmaceutical Products—Acceptance Criteria for Pharmaceutical Preparations and Substances for Pharmaceutical Use

\*see footnote, Chart 10

## 1 INJECTIONS

### INTRODUCTION

Parenteral articles are preparations intended for injection through the skin or other external boundary tissue, rather than through the alimentary canal, so that the active substances they contain are administered, using gravity or force, directly into a blood vessel, organ, tissue, or lesion. Parenteral articles are prepared scrupulously by methods designed to ensure that they meet Pharmacopeial requirements for sterility, pyrogens, particulate matter, and other contaminants, and, where appropriate, contain inhibitors of the growth of microorganisms. An Injection is a preparation intended for parenteral administration and/or for constituting or diluting a parenteral article prior to administration.

### NOMENCLATURE AND DEFINITIONS

#### Nomenclature\*

The following nomenclature pertains to five general types of preparations, all of which are suitable for, and intended for, parenteral administration. They may contain buffers, preservatives, or other added substances.

1. [DRUG] Injection—Liquid preparations that are drug substances or solutions thereof.
2. [DRUG] for Injection—Dry solids that, upon the addition of suitable vehicles, yield solutions conforming in all respects to the requirements for Injections.
3. [DRUG] Injectable Emulsion—Liquid preparations of drug substances dissolved or dispersed in a suitable emulsion medium.
4. [DRUG] Injectable Suspension—Liquid preparations of solids suspended in a suitable liquid medium.
5. [DRUG] for Injectable Suspension—Dry solids that, upon the addition of suitable vehicles, yield preparations conforming in all respects to the requirements for Injectable Suspensions.

#### Definitions

##### pharmacy bulk package

A Pharmacy bulk package is a container of a sterile preparation for parenteral use that contains many single doses. The contents are intended for use in a pharmacy admixture program and are restricted to the preparation of admixtures for infusion or, through a sterile transfer device, for the filling of empty sterile syringes.

The closure shall be penetrated only one time after constitution with a suitable sterile transfer device or dispensing set which allows measured dispensing of the contents. The Pharmacy bulk package is to be used only in a suitable work area such as a laminar flow hood (or an equivalent clean air compounding area).

Designation as a Pharmacy bulk package is limited to preparations from Nomenclature categories 1, 2, or 3 as defined above. Pharmacy bulk packages, although containing more than one single dose, are exempt from the multiple-dose container volume limit of 30 mL and the requirement that they contain a substance or suitable mixture of substances to prevent the growth of microorganisms.

Where a container is offered as a Pharmacy bulk package, the label shall (a) state prominently "Pharmacy Bulk Package—Not for direct infusion," (b) contain or refer to information on proper techniques to help assure safe use of the product, and (c) bear a statement limiting the time frame in which the container may be used once it has been entered, provided it is held under the labeled storage conditions.

#### large- and small-volume injections

Where used in this Pharmacopeia, the designation Large-volume intravenous solution applies to a single-dose injection that is intended for intravenous use and is packaged in containers labeled as containing more than 100 mL. The designation Small-volume Injection applies to an Injection that is packaged in containers labeled as containing 100 mL or less.

## biologics

The Pharmacopeial definitions for sterile preparations for parenteral use generally do not apply in the case of the biologics because of their special nature and licensing requirements (see [Biologics \(1041\)](#)).

### INGREDIENTS

#### Vehicles and Added Substances

**Aqueous Vehicles**— The vehicles for aqueous Injections meet the requirements of the [Pyrogen Test \(151\)](#) or the [Bacterial Endotoxins Test \(85\)](#), whichever is specified. Water for Injection generally is used as the vehicle, unless otherwise specified in the individual monograph. Sodium chloride may be added in amounts sufficient to render the resulting solution isotonic; and Sodium Chloride Injection, or Ringer's Injection, may be used in whole or in part instead of Water for Injection, unless otherwise specified in the individual monograph. For conditions applying to other adjuvants, see Added Substances in this chapter.

**Other Vehicles**— Fixed oils used as vehicles for nonaqueous Injections are of vegetable origin, are odorless or nearly so, and have no odor suggesting rancidity. They meet the requirements of the test for Solid paraffin under Mineral Oil, the cooling bath being maintained at  $10^{\circ}$ , have a Saponification Value between 185 and 200 (see [Fats and Fixed Oils \(401\)](#)), have an Iodine Value between 79 and 141 (see [Fats and Fixed Oils \(401\)](#)), and meet the requirements of the following tests.

**Unsaponifiable Matter**— Reflux on a steam bath 10 mL of the oil with 15 mL of sodium hydroxide solution (1 in 6) and 30 mL of alcohol, with occasional shaking until the mixture becomes clear. Transfer the solution to a shallow dish, evaporate the alcohol on a steam bath, and mix the residue with 100 mL of water: a clear solution results.

**Free Fatty Acids**— The free fatty acids in 10 g of oil require for neutralization not more than 2.0 mL of 0.020 N sodium hydroxide (see [Fats and Fixed Oils \(401\)](#)).

Synthetic mono- or diglycerides of fatty acids may be used as vehicles, provided they are liquid and remain clear when cooled to  $10^{\circ}$  and have an Iodine Value of not more than 140 (see [Fats and Fixed Oils \(401\)](#)).

These and other nonaqueous vehicles may be used, provided they are safe, in the volume of Injection administered, and also provided they do not interfere with the therapeutic efficacy of the preparation or with its response to prescribed assays and tests.

**Added Substances**— Suitable substances may be added to preparations intended for injection to increase stability or usefulness, unless proscribed in the individual monograph, provided they are harmless in the amounts administered and do not interfere with the therapeutic efficacy or with the responses to the specified assays and tests. No coloring agent may be added, solely for the purpose of coloring the finished preparation, to a solution intended for parenteral administration (see also Added Substances under General Notices and [Antimicrobial Effectiveness Testing \(51\)](#)).

Observe special care in the choice and use of added substances in preparations for injection that are administered in a volume exceeding 5 mL. The following maximum limits prevail unless otherwise directed: for agents containing mercury and the cationic, surface-active compounds, 0.01%; for chlorobutanol, cresol, phenol, and similar types of substances, 0.5%; and for sulfur dioxide, or an equivalent amount of the sulfite, bisulfite, or metabisulfite of potassium or sodium, 0.2%.

A suitable substance or mixture of substances to prevent the growth of microorganisms must be added to preparations intended for injection that are packaged in multiple-dose containers, regardless of the method of sterilization employed, unless one of the following conditions prevails: (1) there are different directions in the individual monograph; (2) the substance contains a radionuclide with a physical half-life of less than 24 hours; and (3) the active ingredients are themselves antimicrobial. Such substances are used in concentrations that will prevent the growth of or kill microorganisms in the preparations for injection. Such substances also meet the requirements of [Antimicrobial Effectiveness Testing \(51\)](#) and [Antimicrobial Agents—Content \(341\)](#). Sterilization processes are employed even though such substances are used (see also [Sterilization and Sterility Assurance of Compendial Articles \(1211\)](#)). The air in the container may be evacuated or be displaced by a chemically inert gas. Where specified in a monograph, information regarding sensitivity of the article to oxygen is to be provided in the labeling.

### LABELS AND LABELING

#### Labeling

**note**—See definitions of "label" and "labeling" in Labeling in the section Preservation, Packaging, Storage, and Labeling of the General Notices and Requirements.

The label states the name of the preparation; in the case of a liquid preparation, the percentage content of drug or amount of drug in a specified volume; in the case of a dry preparation, the amount of active ingredient; the route of administration; a statement of storage conditions and an expiration date; the name and place of business of the manufacturer, packer, or distributor; and an identifying lot number. The lot number is capable of yielding the complete manufacturing history of the specific package, including all manufacturing, filling, sterilizing, and labeling operations.

Where the individual monograph permits varying concentrations of active ingredients in the large-volume parenteral, the concentration of each ingredient named in the official title is stated as if part of the official title, e.g., Dextrose Injection 5%, or Dextrose (5%) and Sodium Chloride (0.2%) Injection.

The labeling includes the following information if the complete formula is not specified in the individual monograph: (1) In the case of a liquid preparation, the percentage content of each ingredient or the amount of each ingredient in a specified volume, except that ingredients added to adjust to a given pH or to make the solution isotonic may be declared by name and a statement of their effect; and (2) in the case of a dry preparation or other preparation to which a diluent is intended to be added before use, the amount of each ingredient, the composition of recommended diluent(s) [the name(s) alone, if the formula is specified in the individual monograph], the amount to be used to attain a specific concentration of active ingredient and the final volume of solution so obtained, a brief description of the physical appearance of the constituted solution, directions for proper storage of the constituted solution, and an expiration date limiting the period during which the constituted solution may be expected to have the required or labeled potency if it has been stored as directed.

Containers for Injections that are intended for use as dialysis, hemofiltration, or irrigation solutions and that contain a volume of more than 1 L are labeled to indicate that the contents are not intended for use by intravenous infusion.

Injections intended for veterinary use are labeled to that effect.

The container is so labeled that a sufficient area of the container remains uncovered for its full length or circumference to permit inspection of the contents.

strength and total volume for single- and multiple-dose injectable drug products

For single-dose and multiple-dose injectable drug products, the strength per total volume should be the primary and prominent expression on the principal display panel of the label, followed in close proximity by strength per mL enclosed by parentheses. For containers holding a volume of less than 1 mL, the strength per fraction of a mL should be the only expression of strength. Strength per single mL should be expressed as mg/mL, not mg/1 mL.

The following formats are acceptable for contents of greater than 1 mL:

Total strength/total volume: 500 mg/10 mL

Strength/mL: 50 mg/mL

or

Total strength/total volume: 25,000 Units/5 mL

Strength/mL: 5,000 Units/mL

The following format is acceptable for contents of less than 1 mL: 12.5 mg/0.625 mL

There are, however, some exceptions to expressing strength per total volume. In certain cases, the primary and prominent expression of the total drug content per container would not be effective in preventing medication errors (e.g., insulin). An example is the use of lidocaine or other similar drugs used as a local anesthetic where the product is ordered and

...nistered by percentage (e.g., 1%, 2%) or a local anesthetic in combination with epinephrine that is expressed as a ratio (e.g., 1:100,000). In such cases, the total strength should be expressed: for example, 1% (100 mg/10 mL). Dry solids, which need to be reconstituted, should follow the same format, with the exception that only the total strength of the drug should be listed, not the strength/total volume or strength/mL.

(Official February 1, 2009)

Aluminum in Large-Volume Parenterals (LVPs), Small-Volume Parenterals (SVPs), and Pharmacy Bulk Packages (PBPs) Used in Total Parenteral Nutrition (TPN) Therapy

- a. The aluminum content of LVPs used in TPN therapy must not exceed 25 µg per L (µg/L).
- b. The package insert of LVPs used in TPN therapy must state that the drug product contains no more than 25 µg of aluminum per L. This information must be contained in the "Precautions" section of the labeling of all LVPs used in TPN therapy.
- c. If the maximum amount of aluminum in SVPs and PBPs is 25 µg per L (µg/L) or less, instead of stating the exact amount of aluminum that each contains, as in paragraph (d), the immediate container label for SVPs and PBPs used in the preparation of TPN parenterals (with exceptions as noted below) may state: "Contains no more than 25 µg/L of aluminum". If the SVP or PBP is a lyophilized powder, the immediate container label may state the following: "When reconstituted in accordance with the package insert instructions, the concentration of aluminum will be no more than 25 µg/L".
- d. The maximum level of aluminum at expiry must be stated on the immediate container label of all SVPs and PBPs used in the preparation of TPN parenterals and injectable emulsions. The aluminum content must be stated as follows: "Contains no more than \_\_\_\_ µg/L of aluminum". The immediate container label of all SVPs and PBPs that are lyophilized powder used in the preparation of TPN solutions must contain the following statement: "When reconstituted in accordance with the package insert instructions, the concentration of aluminum will be no more than \_\_\_\_ µg/L." This maximum amount of aluminum must be stated as the highest one of the following three levels:
  1. The highest level for the batches produced during the last three years
  2. The highest level for the latest five batches
  3. The maximum level in terms of historical levels, but only until completion of production of the first five batches after July 26, 2004.

The package insert for all LVPs, SVPs, and PBPs used in the preparation of TPN products must contain a warning statement. This warning must be contained in the "Warning" section of the labeling and must state the following: "WARNING: This product contains aluminum that may be toxic. Aluminum may reach toxic levels with prolonged parenteral administration if kidney function is impaired. Premature neonates are particularly at risk because their kidneys are immature, and they require large amounts of calcium and phosphate solutions that contain aluminum. Research indicates that patients with impaired kidney function, including premature neonates, who receive parenteral levels of aluminum at greater than 4 to 5 µg per kg per day accumulate aluminum at levels associated with central nervous system and bone toxicity. Tissue loading may occur at even lower rates of administration of TPN products."

## PACKAGING

### Containers for Injections

Containers, including the closures, for preparations for injections do not interact physically or chemically with the preparations in any manner to alter the strength, quality, or purity beyond the official requirements under the ordinary or customary conditions of handling, shipment, storage, sale, and use. The container is made of material that permits inspection of the contents. The type of glass preferable for each parenteral preparation is usually stated in the individual monograph. Unless otherwise specified in the individual monograph, plastic containers may be used for packaging injections (see [Containers—Plastics \(661\)](#)).

For definitions of single-dose and multiple-dose containers, see [Containers in the General Notices and Requirements](#). Containers meet the requirements under [Containers—Glass \(660\)](#) and [Containers—Plastics \(661\)](#).

Containers are closed or sealed in such a manner as to prevent contamination or loss of contents. Validation of container integrity must demonstrate no penetration of microbial contamination or chemical or physical impurities. In addition, the solutes and the vehicle must maintain their specified total and relative quantities or concentrations when exposed to anticipated extreme conditions of manufacturing and processing, and storage, shipment, and distribution. Closures for multiple-dose containers permit the withdrawal of the contents without removal or destruction of the closure. The closure permits penetration by a needle and, upon withdrawal of the needle, closes at once, protecting the container against contamination. Validation of the multiple-dose container integrity must include verification that such a package prevents microbial contamination or loss of product contents under anticipated conditions of multiple entry and use.

Piggyback containers are usually intravenous infusion containers used to administer a second infusion through a connector of some type or an injection port on the administration set of the first fluid, thereby avoiding the need for another injection site on the patient's body. Piggyback containers are also known as secondary infusion containers.

### Potassium Chloride for Injection Concentrate

The use of a black closure system on a vial (e.g., a black flip-off button and a black ferrule to hold the elastomeric closure) or the use of a black band or series of bands above the constriction on an ampul is prohibited, except for Potassium Chloride for Injection Concentrate.

### Neuromuscular Blocking and Paralyzing Agents

All injectable preparations of neuromuscular blocking agents and paralyzing agents must be packaged in vials with a cautionary statement printed on the ferrules or cap overseals. Both the container cap ferrule and the cap overseal must bear in black or white print (whichever provides the greatest color contrast with the ferrule or cap color) the words: "Warning: Paralyzing Agent" or "Paralyzing Agent" (depending on the size of the closure system). Alternatively, the overseal may be transparent and without words, allowing for visualization of the warning labeling on the closure ferrule.

### Containers for Sterile Solids

Containers, including the closures, for dry solids intended for parenteral use do not interact physically or chemically with the preparation in any manner to alter the strength, quality, or purity beyond the official requirements under the ordinary or customary conditions of handling, shipment, storage, sale, and use.

A container for a sterile solid permits the addition of a suitable solvent and withdrawal of portions of the resulting solution or suspension in such manner that the sterility of the product is maintained.

Where the Assay in a monograph provides a procedure for the Assay preparation, in which the total withdrawable contents are to be withdrawn from a single-dose container with a hypodermic needle and syringe, the contents are to be withdrawn as completely as possible into a dry hypodermic syringe of a rated capacity not exceeding three times the volume to be withdrawn and fitted with a 21-gauge needle not less than 2.5 cm (1 inch) in length, with care being taken to expel any air bubbles, and discharged into a container for dilution and assay.

### Volume in Container

Each container of an injection is filled with sufficient excess of the labeled "size" or that volume which is to be withdrawn. See [Injections](#) under [Pharmaceutical Dosage Forms \(1151\)](#). determination of volume of injection in containers

Suspensions and emulsions must be shaken before withdrawal of the contents and before the determination of the density. Oily and viscous preparations may be warmed according to the instructions on the label, if necessary, and thoroughly shaken immediately before removing the contents. The contents are then cooled to 20°–25°C before measuring the volume.

Single-Dose Containers— Select 1 container if the volume of the container is 10 mL or more, 3 containers if the nominal volume is more than 3 mL and less than 10 mL, or 5 containers if the nominal volume is 3 mL or less. Take up individually the total contents of each container selected into a dry syringe of a capacity not exceeding three times the volume to be measured and fitted with a 21-gauge needle not less than 2.5 cm (1 inch) in length. Expel any air bubbles from the syringe and needle, and then discharge the contents of the syringe, without emptying the needle, into a standardized, dry cylinder (graduated to contain rather than to deliver the designated volumes) of such size that the volume to be measured occupies at least 40% of its graduated volume. Alternatively, the volume of the contents in mL may be calculated as the mass, in g, divided by the density. For containers with a nominal volume of 2 mL or less, the contents of a sufficient number of containers may be pooled to obtain the volume required for the measurement, provided that a separate,

... syringe assembly is used for each container. The contents of containers holding 10 mL or more may be determined by means of opening them and emptying the contents directly into the graduated cylinder or tared beaker.

The volume is not less than the nominal volume in the case of containers examined individually or, in the case of containers with a nominal volume of 2 mL or less, is not less than the sum of the nominal volumes of the containers taken collectively.

**Multi-Dose Containers**— For Injections in multiple-dose containers labeled to yield a specific number of doses of a stated volume, select 1 container, and proceed as directed for single-dose containers, using the same number of separate syringe assemblies as the number of doses specified. The volume is such that each syringe delivers not less than the stated dose.

**Injections in Cartridges or Prefilled Syringes**— Select 1 container if the volume is 10 mL or more, 3 containers if the nominal volume is more than 3 mL and less than 10 mL, or 5 containers if the nominal volume is 3 mL or less. If necessary, fit the containers with the accessories required for their use (needle, piston, syringe) and transfer the entire contents of each container without emptying the needle into a dry tared beaker by slowly and constantly depressing the piston. Determine the volume in mL, calculated as the mass, in g, divided by the density.

The volume measured for each of the containers is not less than the nominal volume.

**Large-Volume Intravenous Solutions**— For intravenous solutions, select 1 container. Transfer the contents into a dry measuring cylinder of such a capacity that the volume to be determined occupies at least 40% of the nominal volume of the cylinder. Measure the volume transferred.

The volume is not less than the nominal volume.

#### Labeling on Ferrules and Cap Overseals

Only cautionary statements are to appear on the top (circle) surface of the ferrule or cap overseal of a vial containing an injectable product. A cautionary statement is one intended to prevent an imminent life-threatening situation if the injectable drug is used inappropriately. Examples of such statements include but are not limited to the following: "Warning", "Dilute Before Using", "Paralyzing Agent", "I.M. Use Only", and "Chemotherapy".

The text must be in contrasting color and conspicuous under ordinary conditions of use. The cautionary statement may appear solely on the ferrule, provided the cap overseal is constructed so as to allow the cautionary statement beneath the cap to be readily legible.

Identifying numbers or letters, such as code numbers, lot numbers, etc., may appear on the side (skirt) surface of the ferrule on vials containing injectable products. The appearance of such identifying data on the skirt surface of the ferrule, placed where it does not detract from, or interfere with, the cautionary statement on the top surface, should be considered to be a beneficial attribute of the in-process quality control of a product throughout the manufacturing process. Any anticounterfeiting scheme must not detract from or interfere with the cautionary statements.

Under no circumstances would advertising such as company names, logos, or product names be permitted to appear on the top (circle) surface of any ferrule or cap overseal.

(Official February 1, 2009)  
Packaging and Storage

The volume of injection in single-dose containers provides the amount specified for parenteral administration at one time and in no case is more than sufficient to permit the withdrawal and administration of 1 L.

Preparations intended for intraspinal, intracisternal, or peridural administration are packaged only in single-dose containers.

Unless otherwise specified in the individual monograph, a multiple-dose container contains a volume of Injection sufficient to permit the withdrawal of not more than 30 mL.

The following injections are exempt from the 1-L restriction of the foregoing requirements relating to packaging:

1. Injections packaged for extravascular use as irrigation solutions or peritoneal dialysis solutions
2. Injections packaged for extravascular use as parenteral nutrition or as replacement or substitution fluid to be administered continuously during hemofiltration

Injections packaged for intravascular use that may be used for intermittent, continuous, or bolus replacement fluid administration during hemodialysis or other procedures, unless excepted above, must conform to the 1-L restriction.

Injections labeled for veterinary use are exempt from packaging and storage requirements concerning the limitation to single-dose containers and the limitation on the volume of multiple-dose containers.

#### FOREIGN AND PARTICULATE MATTER

All articles intended for parenteral administration shall be prepared in a manner designed to exclude particulate matter as defined in [Particulate Matter in Injections \(788\)](#) and other foreign matter. Each final container of all parenteral preparations shall be inspected to the extent possible for the presence of observable foreign and particulate matter (hereafter termed "visible particulates") in its contents. The inspection process shall be designed and qualified to ensure that every lot of all parenteral preparations is essentially free from visible particulates. Qualification of the inspection process shall be performed with reference to particulates in the visible range of a type that might emanate from the manufacturing or filling process. Every container whose contents shows evidence of visible particulates shall be rejected. The inspection for visible particulates may take place when inspecting for other critical defects, such as cracked or defective containers or seals, or when characterizing the appearance of a lyophilized product.

Where the nature of the contents or the container-closure system permits only limited capability for the inspection of the total contents, the 100% inspection of a lot shall be supplemented with the inspection of constituted (e.g., dried) or withdrawn (e.g., dark amber container) contents of a sample of containers from the lot.

All large-volume Injections for single-dose infusion and small-volume Injections are subject to the light obscuration or microscopic procedures and limits for subvisible particulate matter set forth in [Particulate Matter in Injections \(788\)](#), unless otherwise specified in the individual monograph. An article packaged as both a large-volume and a small-volume Injection meets the requirements set forth for small-volume Injections where the container is labeled as containing 100 mL or less, if the individual monograph states a test for [Particulate Matter \(788\)](#); it meets the requirements set forth for large-volume Injections for single-dose infusion where the container is labeled as containing more than 100 mL. Injections administered exclusively by the intramuscular or subcutaneous route or packaged and labeled for use as irrigating solutions are exempt from requirements for [Particulate Matter \(788\)](#).

#### STERILITY

**Sterility Tests**— Preparations for injection meet the requirements under [Sterility Tests \(71\)](#).

#### CONSTITUTED SOLUTIONS

Dry solids from which constituted solutions are prepared for injection bear titles of the form [DRUG] for Injection. Because these dosage forms are constituted at the time of use by the health care practitioner, tests and standards pertaining to the solution as constituted for administration are not included in the individual monographs on sterile dry solids or liquid concentrates. However, in the interest of assuring the quality of injection preparations as they are actually administered, the following nondestructive tests are provided for demonstrating the suitability of constituted solutions when they are prepared just prior to use.

**Completeness and Clarity of Solution**— Constitute the solution as directed in the labeling supplied by the manufacturer for the sterile dry dosage form.  
A: The solid dissolves completely, leaving no visible residue as undissolved matter.

B: The constituted solution is not significantly less clear than an equal volume of the diluent or of Purified Water contained in a similar vessel and examined similarly.

Particulate Matter—Constitute the solution as directed in the labeling supplied by the manufacturer for the sterile dry dosage form: the solution is essentially free from particles of foreign matter that can be observed on visual inspection.

\* This nomenclature has been adopted by the USP Drug Nomenclature Committee for implementation by supplemental revisions of USP 23-NF 18. For currently official monograph titles in the form Sterile [DRUG] that have not yet been revised, the following nomenclature continues in use in this Pharmacopeia: (1) medicaments or solutions or emulsions thereof suitable for injection, bearing titles of the form [DRUG] Injection; (2) dry solids or liquid concentrates containing no buffers, diluents, or other added substances, and which, upon the addition of suitable solvents, yield solutions conforming in all respects to the requirements for injections, and which are distinguished by titles of the form Sterile [DRUG]; (3) preparations the same as those described under (2) except that they contain one or more buffers, diluents, or other added substances, and which are distinguished by titles of the form [DRUG] for Injection; (4) solids which are suspended in a suitable fluid medium and which are not to be injected intravenously or into the spinal canal, distinguished by titles of the form Sterile [DRUG] Suspension; and (5) dry solids which, upon the addition of suitable vehicles, yield preparations conforming in all respects to the requirements for Sterile Suspensions, and which are distinguished by titles of the form Sterile [DRUG] for Suspension.

Auxiliary Information—Please [check for your question in the FAQs](#) before contacting USP.

Pharmacopeial Forum: Volume No. 34(4) Page 1020

#### 11 USP REFERENCE STANDARDS

USP Reference Standards are highly characterized specimens of drug substances, excipients, reportable impurities, degradation products, compendial reagents, and performance calibrators.

They are explicitly required in many Pharmacopeial assays and tests and are provided solely for such use. Assessment of the suitability for use in other application(s) rests with the purchaser.

#### AUTHORITY FOR ESTABLISHMENT AND RELEASE

USP Reference Standards are established and released under the authority of the USPC Board of Trustees upon recommendation of the USP Reference Standards Expert Committee, which approves each lot as being suitable for use in its compendial applications. For some Reference Standards a preliminary review and approval is sought from other Expert Committees of the Council of Experts.

The distribution of controlled substances is subject to the regulations and licensing provisions of the Drug Enforcement Administration of the Department of Justice.

Industry Advisory Panels and other expert groups (such as Project Teams) may be assembled to advise USP on various aspects of the Reference Standards Program.

#### HISTORY

Future availability of the first USP Reference Standards was announced in 1926 (USP X) "... in order to facilitate the adoption of the biological assay standards of the Pharmacopoeia, and to provide a greater degree of uniformity in their application." The list of USP Reference Standards that in 1936 comprised 6 items has grown to almost 1650 in 2004, and the collection has tracked the progress in pharmaceutical sciences: The first vitamins (Cod Liver Oil) and the first enzyme (Pepsin) in 1936; the first sulfonamide (Sulfanilamide) and the first hormones (Insulin; Posterior Pituitary) in 1942; the first performance standards (Melting Point Standards) in 1947; the first penicillin (Penicillin G Sodium) in 1950; the first recombinant-DNA technology protein (Insulin Human) in 1985, etc.

The continuous increase in the number of USP Reference Standards (over 100 new standards are being developed yearly) reflects not only the increase in the number of monographs and General Chapters, but also the development and extensive use of modern analytical methodology (such as chromatography, spectrophotometry, biological and biochemical assays, etc.) which require measurements relative to a reference standard.

#### NOMENCLATURE

Standards designated as USP Reference Standards (USP RS) are, with a few exceptions, required for use in USP-NF monographs or General Chapters. The exceptions include current lots of USP and NF Reference Standards for which uses are no longer specified in the current USP or NF but for which sufficient demand remains (upon depletion of the current lots, future lots will be designated as Authentic Substances). Reference Standards specified in monographs developed by USP that are not intended for publication in the USP—NF, Reference Standards specified in the current edition of the Food Chemicals Codex (labeled with an additional designation "FCC"), and Fluoride Dentifrices (evaluated and distributed by agreement with the FDA and the Cosmetics, Toiletries, and Fragrances Association). A USP Reference Standard required in a monograph or General Chapter proposed in Pharmacopeial Forum may be released in advance of the official date of the proposed PF revision.

Reference Standards currently labeled as "NF Reference Standards" will eventually all be designated and labeled as "USP Reference Standards" pursuant to the consolidation of USP and NF within the USPC as of January 2, 1975. Meanwhile, where a USP Reference Standard is called for, the corresponding substance labeled as an "NF Reference Standard" may be used.

As a service, the USPC tests and distributes additional Authentic Substances (designated by AS) not currently required for use in a USP monograph or General Chapter. These also are provided under the supervision of the USP Reference Standards Expert Committee. They are highly characterized samples of chemicals, including substances of abuse, which are collaboratively tested and made available as a service primarily to analytical, clinical, pharmaceutical, and research laboratories. Such materials may be used for identification, method development, evaluation of method performance, or other applications as found suitable and validated by the user.

#### Authentic Visual References

Unlike chemical reference standards, Authentic Visual References (AVRs) are not used in chemical analyses. Instead, the AVRs are visual images used by analysts to compare certain test articles to ensure that they meet compendial requirements and are incorporated by reference into the monograph. Approval of AVRs for use in a monograph is the decision of the Expert Committee that approves the specific monograph.

#### DIVERSITY AND IMPLICATIONS

The USP Reference Standards collection is very diverse in terms of appearance, chemical structure, composition, and uses. This diversity has significant implications for the way the materials are tested, packaged, stored, and utilized.

The USP Reference Standards may be crystalline or amorphous powders, volatile or viscous liquids, solutions or suspensions, gels or pastes, plastic sheets, etc. In chemical structure they vary from simple inorganic salts to proteins produced by recombinant DNA technology. Some are highly-purified single components, while others are complex mixtures (in most cases extracted from plant or animal sources).

## USES OF USP REFERENCE STANDARDS

The official and authorized uses of USP Reference Standards are specified in the USP monographs and General Chapters and they include the following:

- quantitative uses in assays for drug substances and formulations, limit tests, or blanks and controls
- qualitative uses, such as identification tests, system suitability tests, chromatographic peak markers, etc.
- performance standards and calibrators, such as dissolution calibrators, melting point standards, the particle count set, etc.

As discussed under Nomenclature, USP also establishes and distributes standards not specified for use in a USP monograph or General Chapter.

The most frequent applications of USP Reference Standards (USP RS) are in chromatographic and spectroscopic methodologies. However, they are also widely used in biological and biochemical applications, such as microbial assays for antibiotics, enzymatic reactions, cell-culture tests, whole-animal tests; in thermal analysis for polymers; and in titration, etc.

Some of the most frequently used USP RS are those utilized in General Chapters tests such as [Dissolution](#) (711), [Bacterial Endotoxins Test](#) (85), [Total Organic Carbon](#) (643), and [Particulate Matter in Injections](#) (788).

## STEPS IN ESTABLISHING A USP REFERENCE STANDARD

The establishment of a new USP Reference Standard is triggered by the proposal of a new monograph or of a revision of an existing monograph by the inclusion of a test requiring a new USP RS. The need for a new lot of an existing USP Reference Standard is identified when its inventory reaches a pre-established threshold. The new lot is designated as a "replacement lot" if a new bulk material is to be procured or as a "continuation lot" if the candidate material is another portion of the bulk used for the existing official lot.

USP scientists generate a set of documents including procurement specifications and a testing protocol. A bulk material is obtained, generally from a major manufacturer of the article. The material is tested and characterized in an inter-laboratory collaborative study organized according to the protocol designed at USP Headquarters. The results are evaluated by USP Staff, additional testing or investigations are performed when necessary, and a report is compiled and presented for review and approval to the USP Reference Standards Expert Committee. After approval the material is subdivided (if not packaged prior to the collaborative study), labeled, quality checks are performed, and the standard is made available for distribution. If a candidate material is found to be unsuitable by USP scientific staff or by the Reference Standards Committee, a new bulk is procured and tested.

## COLLABORATIVE STUDY FOR THE EVALUATION OF A USP RS CANDIDATE MATERIAL

The goals of the evaluation study are to confirm the identity and assess the purity of the material, to determine its suitability for use in the official applications, to provide the user with all the necessary information and directions for use, and to acquire time-zero information for future continued-suitability-for-use studies.

USP scientists design a detailed testing protocol that includes the following elements: types of tests, number of tests, number of collaborators, number of replicates, and references to the procedures to be used.

The following factors are considered when designing the study protocol: the compendial status of the standard, its official uses, the history of the standard, its composition and complexity, the characteristics of the methodology, and the availability of material and of competent laboratories.

The testing protocol may comprise visual and microscopic evaluation; identification tests (more elaborate for first-time standards); determination of physical-chemical constants (e.g., melting range, specific rotation, refractive index, specific gravity, etc); chromatographic and electrophoretic purity tests; inorganic contaminants determination; volatile tests (water, solvents); functional group analysis (such as titrations, UV absorptivity, elemental analysis); thermal analysis; and assays against another well-characterized standard (a previous lot, an international standard, etc). Specialized testing is implemented where appropriate, such as for dissolution calibrators and the particle count set, for standards that define an attribute (negative and positive bioreaction, ion-exchange capacity, permeability diameter), and for biological standards that define a Unit of activity (heparin, endotoxin, enzymes, complex antibiotics). Vapor sorption analysis may also be performed to assist in determining packaging and storage conditions, and directions for use. For lyophilized single-use USP RS, acceptable vial content reproducibility and stability of the lyophilized form are demonstrated.

The number of collaborators is generally not less than three (two outside of USP); but it can increase significantly, especially when the methodology is complex or does not have a high level of precision or when potential users express an interest in participating in the evaluation of the candidate. (Participation in all evaluation studies is open to all competent, interested parties.) Where appropriate, statistical control is exercised in the design of the evaluation study and in the analysis of the results. The USP Reference Standards Laboratory and the FDA laboratories participate in almost all evaluation studies. Other collaborators include Health Canada, the USP Research and Development Laboratory, and industrial and academic laboratories from the United States and from abroad.

## BIOLOGICAL REFERENCE STANDARDS

The World Health Organization, an agency of the United Nations, manages a program providing International Standards for biological materials.

USP collaborates closely with the WHO in the harmonization of analytical methodology, in the definition of the units of potency, and in some cases to share in the preparation of a reference standard. In many cases the USP Units and the International Units of potency are identical.

## SUITABILITY FOR USE AND PURITY ASSIGNMENT

The data collected in the collaborative evaluation study are analyzed to determine whether the material is suitable for its monograph-designated use. Characterization data and results must be considered as a whole when evaluating suitability for intended use, assignment strategy, and assigned value. For Reference Standards used in quantitative applications, this includes the determination of a calculation value to be used in the compendial utilization of the standard.

The method of choice in computing the assigned value is a mass balance analysis using independently determined components such as moisture, solvent residues, inorganic residues, chromatographic impurities, and ion content. The assay results against a previous lot or against another validated standard and the results of the functional group analysis are for confirmatory purposes only. Exceptions to the mass balance approach include many biological Reference Standards, especially those which define the Unit of activity.

The number of significant figures in the labeled calculation value is a function of the use of the standard and the number of significant figures in the acceptance range or limit. Generally, Reference Standards used in assays are labeled with three significant figures and standards used in limit tests with two significant figures. Reference Standards having multiple applications in different methodologies may require separate assay-specific assignments.

The assigned value is labeled without any associated uncertainty. However, for calibration standards, the labeled value is a range, determined by a statistical analysis of the results. Previous approaches used a purity threshold above which the content was no longer labeled, and the analyst was directed to use a default value of 100.0%. This approach is no longer in use, but older lots of standards have not been re-labeled, and users should continue to apply the default 100.0% value for compendial quantitative applications.

For antibiotics, the designation "µg/mg" is sometimes used as a unit of biological activity, and values greater than 1000 µg/mg may be assigned to some of these standards. This can happen when the first standard is assigned a value higher than its actual purity and subsequent standards of higher purity are defined relative to the previous lot. A relatively overstated assigned value can also result when less selective separation techniques are replaced with more selective modern methodologies. As a result, the original content might have been assumed to be higher than the actual level.

No value is assigned to standards having only qualitative applications.

A report compiling the results of the evaluation study and including the proposed label text is submitted for review and approval to the USP Reference Standards Expert Committee.

## LABEL TEXT

The label text is designed to provide the user with all the information needed for the correct storage and usage of the Reference Standard in monograph application(s). The label includes directions for use, safety warnings, required information for controlled substances, and a calculation value for standards with quantitative applications. For calibrators, acceptance ranges are provided. Where necessary, USP Reference Standards are accompanied by additional documentation, such as Technical Sheets or Typical Chromatograms. USP generally does not provide Certificates of Analysis because all the information that the user needs for the official or authorized applications of the standard is provided in the label text and, where necessary, in the additional documentation provided.

Directions for use are lot-specific, and they take precedence over any other indication in the compendium.

Material Safety Data Sheets are generated for every standard that USP distributes. They are available on the USP website.

#### USP REFERENCE STANDARDS EXPERT COMMITTEE

The USP Reference Standards Expert Committee comprises professionals from industry, government agencies and academia from the United States and abroad. It is organized in groups and may be assisted in the review of the evaluation studies by an Industry Advisory Panel. The approval of the evaluation report has to be unanimous.

#### PACKAGING

The USP Reference Standard production process operates under a registered ISO 9001:2000 Quality System and appropriate cGMP principles.

USP Reference Standards are packaged in individual units designed to maintain the integrity of the contained Reference Standard material. The packaging and storage conditions for USP Reference Standards provide protection for all materials even though the material may not need such exceptional protection due to its inherent stability. The most common packaging configurations are vials for solid materials and ampuls for liquids. The packaging environment is determined by the sensitivity of the material to light, oxidation, or atmospheric humidity, and by its toxicity. Where appropriate, containers are filled in a glove box under inert gas and in conditions of controlled low residual humidity. (The need to store such standards under inert gas protection is indicated on the label.) They may also be sealed in a foil bag as an added protective barrier. Ampuls are filled and sealed on an automated device and are typically purged with an inert gas. The most common ampul sizes are 2 mL and 5 mL. Vials may be filled by manual, semi-automated, or fully automated operations. Vials may be of different sizes depending upon the amount of material. The amount of material per individual container depends on the compendial application of the standard and is generally sufficient for several replicates. Larger amounts are provided when additional experiments are required (such as a titrimetric determination of the water content at the time of use). In general, Reference Standard containers are slightly over-filled so that the user can retrieve the labeled, nominal amount of material. Vials are closed with Teflon-lined stoppers and secured with aluminum crimps and a USP-logo tamper-evident seal. Lots using prior vial closure configurations may still be in distribution.

Various considerations may determine the need to provide the standard in single-use containers, mainly for materials with significant handling issues or for those that are available only in small amounts. Such single-use containers are generally filled by lyophilization, and their content is labeled in mass or activity Units per container. If so labeled, the content of the container is to be reconstituted in its entirety without any additional weighing. Instructions for reconstitution are given either on the label or in the monographs where the standard is being used.

#### IMPURITY REFERENCE STANDARDS

The topic of impurities is addressed in several sections of USP, such as General Notices, General Chapters such as [Ordinary Impurities](#) (466), [Impurities in Official Articles](#) (1086), etc. In addition, most of the monographs for drug substances and many of those for formulations include specific tests for the identification or quantitation of impurities. Such tests generally require an official Reference Standard. The development of these impurity Reference Standards is one of the reasons for the continuous accelerated growth of the USP Reference Standards.

In many cases, the materials for impurity Reference Standards are expensive and difficult to procure. Only a limited amount of material may be available—procurement might require custom synthesis—and it may be of lesser quality than the Reference Standard for the official article, requiring purification. The limited amount of material available can affect the testing protocol and the packaging. Impurity Reference Standards might be available as purified single-component materials, solutions, or solid dispersions, or mixtures of more than one impurity. Other options include samples of the official article with a labeled content of impurity(ies), the in-situ generation of the impurity from the official article by a validated specified procedure, the use of relative chromatographic mobilities and relative response factors, or of theoretical values such as UV absorptivities at selective wavelengths.

In earlier editions of the compendium, the impurities were designated by their chemical names. For ease of indexing and searching, these have been gradually replaced with the designation "X Related Compound Y RS," where X is the name of the official article and Y is a sequential alphabetical letter. Reference Standard impurity mixtures might be designated by their use, such as "X System Suitability RS". The conventional names and the chemical names are cross-referenced in the final section of this chapter and in a special section of the Official USP Reference Standards Catalog.

#### CONTINUED SUITABILITY FOR USE PROGRAM

To ensure that the Reference Standards maintain the properties determined at the initial evaluation, USP maintains a Continued Suitability for Use Program. The retesting intervals and protocols are a function of the uses and properties of the standard and of the information available about its stability. Abbreviated protocols use the stability-indicating methodology employed in the initial characterization of the material to confirm the consistency of attributes such as appearance, chromatographic purity, or volatiles content.

#### PROPER USE

Neither the Reference Standards nor the Authentic Substances are intended for use as drugs or as medical devices.

USP Reference Standards do not carry an expiration date as long as they are in distribution. A lot of USP RS may be used in its official applications as long as it is listed as "Current Lot" in the current (most recent) Official USP Reference Standards Catalog. Upon depletion, the lot is designated in the catalog as "Previous Lot" and a "Valid Use Date" is assigned. USP publishes the Official Catalog of Reference Standards (which also includes Authentic Substances) bimonthly as a separate brochure\*. An updated version of the catalog can be found on the USP website at [www.usp.org](http://www.usp.org). It is the responsibility of the user to ascertain that a particular supply of USP Reference Standard has official status either as a "Current Lot" or as a "Previous Lot" within the valid use date.

Many Pharmacopeial tests and assays are based on comparison of a test specimen with a USP Reference Standard. In such cases, measurements are made on preparations of both the test specimen and the Reference Standard. Where it is directed that a Standard solution or a Standard preparation be prepared for a quantitative determination by stepwise dilution or otherwise, it is intended that the Reference Standard substance shall be accurately weighed (see [Weights and Balances](#) (41) and [Volumetric Apparatus](#) (31)). Due account should also be taken of the relatively large errors associated with weighing small masses.

The label text provides the user with directions on the proper use of a Reference Standard. The directions include one of the following options. A Reference Standard may be used as follows:

- As-is, i.e., without any prior treatment or correction for volatiles. This is the preferred option, and it is selected whenever validated data show that the volatiles content is constant over time.
- Immediately after a prior drying under stated conditions. Drying should not be performed in the original container. A portion of the material should be transferred to a separate drying vessel.
- With a correction for the water content or the loss on drying determined on a separate portion of material. Where the titrimetric determination of water is required at the time a Reference Standard is to be used, proceed as directed for Method I under [Water Determination](#) (921). Instrumental or microanalytical methods are acceptable for this purpose. When using typical amounts (about 50 mg of the Reference Standard), titrate with a two- to five-fold dilution of the reagent. Where the determination of the loss on drying on a separate portion of USP Reference Standard is required, proceed as directed on the label. Smaller sample sizes than those required in General Chapter [Loss on Drying](#) may be used.

Driving [731](#) may be used for a USP Reference Standard, provided that the user can obtain a sufficiently accurate result.

Whenever the labeled directions for use require a preliminary drying or a correction for volatiles, it should be performed "at the time" of use. Further experimental details should be controlled by the user's Standard Operating Procedures and good laboratory practices.

#### STORAGE

To serve its intended purpose, each USP Reference Standard must be properly stored, handled, and used. Generally, Reference Standards should be stored in their original stoppered containers away from heat and protected from light. Avoid humid storage areas in particular. Where special storage conditions are necessary, directions are given on the label.

#### RELATIONSHIPS WITH OTHER STANDARDS-SETTING ORGANIZATIONS

USP maintains continuous contact with other organizations that establish Reference Materials for compendial and other purposes, such as the European and the Japanese Pharmacopoeias (through the Pharmacopeial Discussion Group), the World Health Organization, the National Institute for Science and Technology, the Reference Materials Committee of ISO (REMCO), etc.

The specific nature of pharmacopeial reference substances has been officially recognized by ISO-REMCO in the introduction of the ISO Guide 34—General requirements for the competence of reference material producers (Second Edition 2000): "Pharmacopeial standards and substances are established and distributed by pharmacopeial authorities following the general principle of this guide. It should be noted, however, that a different approach is used by the pharmacopeial authorities to give the user the information provided by certificate of analysis and the expiration dates. Also, the uncertainty of their assigned values is not stated since it is negligible in relation to the defined limits of the method-specific assays of the pharmacopoeias for which they are used."

The USP Reference standards section of an individual USP or NF monograph or general chapter names each USP Reference Standard required for assay and test procedures and refers to this chapter for additional information and instructions. It is especially important to refer to the current Supplement to USP and to NF for official revisions listed in the following section.

#### USP REFERENCE STANDARDS SPECIFIED IN USP AND NF MONOGRAPHS AND GENERAL CHAPTERS

note—Consult the latest Supplement or Interim Revision Announcement pertaining to USP and to NF for revisions, additions, or deletions.

Revisions, additions, and deletions of individual USP Reference Standards are listed cumulatively in each Supplement to USP–NF. As a consequence, therefore, it is necessary to consult only the current edition of USP–NF and the latest Supplement for the complete list of USP Reference Standards currently specified in USP–NF monographs and general chapters. The list provides up-to-date and complete names and applicable chemical information for the USP Reference Standards that are in distribution as of the official date of that Supplement.

Revisions of this chapter are implemented continuously via the Interim Revision Announcements that are published in Pharmacopeial Forum. Those interim revisions of USP Reference Standards are cumulatively included in the next USP–NF Supplement.

The alphabetical list that follows constitutes an index of all revisions to this chapter. Thus, it is unnecessary to name repetitively the revised Reference Standards in the general index to the Supplement.

In the list that follows, chemical names are given for many substances (e.g., related compounds) that are not USP or NF monograph articles. Following the name of such a chemical substance RS, the empirical formula and molecular weight, separated by the ♦ symbol, may be given in parentheses if those data are available.

USP Betaxolol Hydrochloride RS .

USP Bethanechol Chloride RS .

USP Bicalutamide RS

USP Bicalutamide Related Compound B RS [(RS)-N-(4-cyano-3-(trifluoromethyl)phenyl)-3-(3-fluorophenylsulfonyl)-2-hydroxy-2-methylpropanamide] (C<sub>18</sub>H<sub>14</sub>F<sub>4</sub>N<sub>2</sub>O<sub>4</sub>S  $\Delta$  430.37) .

USP Powdered Bilberry Extract RS.

USP Bile Salts RS .

USP Positive Bioreaction RS .

USP Biotin RS

USP Biperiden RS

USP Biperiden Hydrochloride RS .

USP Bisacodyl RS

Add the following:

▲USP Bisdesmethoxycurcumin RS. ▲USP32

USP Bis(2-ethylhexyl) Maleate RS (C20H36O4  $\Delta$  340.51).USP 4,4'-Bis[1,2,3,6-tetrahydro-4-(2-oxo-1-benzimidazolinyl)-1-pyridyl]butyrophenone RS (C34H34N6O3  $\Delta$  574.69).

USP Bismuth Citrate RS

USP Bismuth Subsalsalate RS .

USP Bisoctrizole RS.

USP Bisoctrizole Related Compound A RS.

USP Bisoctrizole Resolution Mixture RS.

USP Bisoprolol Fumarate RS .

USP Bleomycin Sulfate RS .

USP Bretylium Tosylate RS .

USP Brinzolamide RS .

USP Brinzolamide Related Compound A RS [brinzolamide (S)-isomer] (C12H21N3O5S3  $\Delta$  383.52).USP Brinzolamide Related Compound B RS [(R-4-amino)-2,3-dihydro-2-(3-methoxypropyl)-4H-thieno[3,2,-e]-thiazine-6-sulfonamide-1,1-dioxide ethandioate 1:1] (C10H17N3O5S3-C2H2O4  $\Delta$  445.49).

USP Bromocriptine Mesylate RS .

USP Bromodiphenhydramine Hydrochloride RS .

USP 8-Bromotheophylline RS [8-bromo-3,7-dihydro-1,3-dimethyl-1H-purine-2,6-dione] (C7H7N4O2Br  $\Delta$  259.06).

USP Brompheniramine Maleate RS .

USP Bumetanide RS .

USP Bumetanide Related Compound A RS [3-amino-4-phenoxy-5-sulfamoylbenzoic acid] (C13H12N2O5S  $\Delta$  308.31).USP Bumetanide Related Compound B RS [3-nitro-4-phenoxy-5-sulfamoylbenzoic acid] (C13H10N2O7S  $\Delta$  338.29).

USP Bupivacaine Hydrochloride RS .

USP Buprenorphine Hydrochloride RS .

USP Buprenorphine Related Compound A RS [21-[3-(1-propenyl)-7 $\alpha$ -[(S)-1-hydroxy-1,2,2-trimethylpropyl]-6,14-endo-ethano-6,7,8,14-tetrahydrooripavine] (C29H41NO4  $\Delta$  467.65).

USP Bupropion Hydrochloride RS .

USP Bupropion Hydrochloride Related Compound A RS [2-(tert-butylamino)-4'-chloropropiophenone hydrochloride] (C13H18ClNO-HCl  $\Delta$  276.21).USP Bupropion Hydrochloride Related Compound B RS [2-(tert-butylamino)-3'-bromopropiophenone hydrochloride] (C13H18BrNO-HCl  $\Delta$  320.66).USP Bupropion Hydrochloride Related Compound C RS [1-(3-chlorophenyl)-2-hydroxy-1-propanone] (C9H9O2Cl  $\Delta$  184.62).

USP Bupropion Hydrochloride Related Compound F RS [1-(3-chlorophenyl)-1-hydroxy-2-propanone] (C9H9O2  $\Delta$  184.62).

USP Buspirone Hydrochloride RS.

USP Butabarbital RS.

USP Butalbital RS.

USP Butamben RS.

USP Butoconazole Nitrate RS.

USP Butorphanol Tartrate RS.

USP 2-tert-Butyl-4-hydroxyanisole RS [C11H16O2  $\Delta$  180.25].

USP 3-tert-Butyl-4-hydroxyanisole RS [C11H16O2  $\Delta$  180.25].

USP Butyl 3-(butylamino)-4-phenoxy-5-sulfamoylbenzoate RS [C21H28N2O5S  $\Delta$  420.53].

USP Butylparaben RS.

Add the following:

▲USP Cabergoline RS. ▲USP32

USP Caffeine RS.

USP Caffeine Melting Point RS.

USP Calcifediol RS.

USP Calcitonin Salmon RS.

USP Calcitonin Salmon Related Compound A RS [N-acetyl-cys1-calcitonin] (C146H243N44O49S2  $\Delta$  3463).

USP Calcitriol RS.

USP Calcitriol Solution RS.

USP Calcium Ascorbate RS.

USP Calcium Gluceptate RS.

USP Calcium Lactate RS.

USP Calcium Lactobionate RS.

USP Calcium Pantothenate RS.

USP Calcium Saccharate RS.

USP Candelilla Wax RS.

USP Capecitabine RS.

USP Capecitabine Related Compound A RS.

USP Capecitabine Related Compound B RS.

USP Capecitabine Related Compound C RS.

USP Capreomycin Sulfate RS .

USP Caprylic Acid RS.

USP Caprylocaproyl Polyoxyglycerides RS .

USP Capsaicin RS .

USP Captopril RS .

USP Captopril Disulfide RS .

USP Carbachol RS .

USP Carbamazepine RS .

USP Carbamazepine Related Compound A RS [10, 11-dihydrocarbamazepine].

USP Carbamazepine Related Compound B RS [iminostilbene].

USP Carbenicillin Indanyl Sodium RS .

USP Carbenicillin Monosodium Monohydrate RS .

USP Carbidopa RS .

USP Carbidopa Related Compound A RS [3-O-methylcarbidopa] (C11H16N2O4  $\Delta$  240.26) .

USP Carbinoxamine Maleate RS .

USP Urea C 13 RS .

USP Carboplatin RS .

USP Carboprost Tromethamine RS.

USP Carisoprodol RS .

USP Carprofen RS.

USP Carprofen Related Compound A RS [carbazole] (C12H9N  $\Delta$  167.21).

USP Carteolol Hydrochloride RS .

USP Carvedilol RS.

USP Carvedilol Related Compound A RS [1-[[9-[2-hydroxy-3-[[2-(2-methoxyphenoxy)ethyl]amino]propyl]-9H-carbazol-4-yl]oxy]-3-[[2-(2-methoxyphenoxy)ethyl]amino]propan-2-ol] .

USP Carvedilol Related Compound B RS [1,1'-[[2-(2-methoxyphenoxy)ethyl]nitrilo]bis[3-(9H-carbazol-4-yloxy)propan-2-ol] .

USP Carvedilol Related Compound C RS [(2RS)-1-[benzyl[2-(2-methoxyphenoxyethyl]amino]-3-(9H-cabazol-4-yloxy)propan-2-ol] .

USP Carvedilol Related Compound D RS [4-(2,3-epoxypropoxy)carbazole] .

USP Carvedilol Related Compound E RS [2-(2-methoxyphenoxy)ethylamine] .

USP Casticin RS .

USP Powdered Cat's Claw Extract RS.

USP Cathinone Hydrochloride RS [ $\alpha$ -aminopropiophenone hydrochloride] (C9H11NO·HCl  $\Delta$  185.65).

USP Cefaclor RS .

USP Cefaclor Delta-3 Isomer RS

USP Cefadroxil RS

USP Cefamandole Lithium RS .

USP Cefamandole Nafate RS .

USP Cefazolin RS

Add the following:

▲USP Cefdinir RS ▲USP32

Add the following:

▲USP Cefdinir Related Compound A RS [(2R)-2-[(Z)-2-(2-aminothiazol-4-yl)-2-(hydroxyimino)acetamido]-2-[(2RS,5RS)-5-methyl-7-oxo-2,4,5,7-tetrahydro-1H-furo[3,4-d][1,3]thiazin-2-yl]acetic acid (other three stereo isomers are also present in this RS)] (C14H15N5O6S2  $\Delta$  413.43). ▲USP32

Add the following:

▲USP Cefdinir Related Compound B RS [(6R,7R)-7-[2-(2-amino-4-thiazolyl)acetamido]-8-oxo-3-vinyl-5-thia-1-azabicyclo[4.2.0]oct-2-ene-2-carboxylic acid] (C14H13N4O4S2  $\Delta$  365.41). ▲USP32

USP Cefepime Hydrochloride RS

USP Cefepime Hydrochloride System Suitability RS— This is a mixture of cefepime hydrochloride related compound A (6R-[6 $\alpha$ ,7 $\beta$ (E)]-1-[[7-[(2-amino-4-thiazolyl) (methoxyimino) acetyl]amino]-2-carboxy-8-oxo-5-thia-1-azabicyclo[4.2.0]oct-2-en-3-yl]methyl]-1-methylpyrrolidinium chloride, monohydrate; (C19H25ClN6O5S2·HCl·H<sub>2</sub>O  $\Delta$  571.50); cefepime related compound B ([6R-trans]-7-[[2-[(2-amino-4-thiazolyl)(methoxyimino)acetyl]amino]-4-thiazolyl](methoxyimino)acetyl]amino)-3-(1-methylpyrrolidinium-1-yl) methyl]-5-thia-1-azabicyclo[4.2.0]oct-3-ene-2-carboxylic acid, inner salt; (C25H29N9O7S3  $\Delta$  663.75); and cefepime hydrochloride.

USP Cefixime RS

USP Choline Chloride RS .

USP Chondroitin Sulfate Sodium RS .

USP Chromium Picolinate RS .

USP Chymotrypsin RS .

USP Ciclopirox RS .

USP Ciclopirox Related Compound A RS [3-cyclohexyl-4,5-dihydro-5-methyl-5-isoxazolyl acetic acid].

USP Ciclopirox Related Compound B RS [6-cyclohexyl-4-methyl-2-pyrone].

USP Ciclopirox Olamine RS .

USP Cilastatin Ammonium Salt RS .

USP Cilostazol RS .

USP Cilostazol Related Compound A RS [6-hydroxy-3,4-dihydro-1H-quinolin-2-one] (C9H9NO2  $\Delta$  163.17).

USP Cilostazol Related Compound B RS [6-[4-(1-cyclohexyl-1H-tetrazol-5-yl)-butoxy]-1H-quinolin-2-one] (C20H25N5O2  $\Delta$  367.45).

USP Cilostazol Related Compound C RS [1-(4-(5-cyclohexyl-1H-tetrazol-1-yl)butyl)-6-(4-(1-cyclohexyl-1H-tetrazol-5-yl)butoxy)-3,4-dihydroquinolin-2(1H)-one] (C31H43N9O3  $\Delta$  589.73).

USP Cimetidine RS .

USP Cimetidine Hydrochloride RS .

USP Cinoxacin RS .

USP Ciprofloxacin RS .

USP Ciprofloxacin Ethylenediamine Analog RS [1-cyclopropyl-6-fluoro-1,4-dihydro-4-oxo-7-[(2-aminoethyl)amino]-3-quinolinecarboxylic acid hydrochloride] (C15H16FN3O3·HCl  $\Delta$  341.77).

USP Ciprofloxacin Hydrochloride RS .

USP Cisplatin RS .

USP Citalopram Hydrobromide RS. .

USP Citalopram Related Compound A RS [1-(3-dimethylaminopropyl)-1-(4'-fluorophenyl)-1,3-dihydroisobenzofuran-5-carboxamide] (C20H23FN2O2  $\Delta$  342.22).

USP Citalopram Related Compound B RS [1-(3-dimethylaminopropyl)-1-(4-fluorophenyl)-3-hydroxy-1,3-dihydroisobenzofuran-5-carbonitrile] (C20H21FN2O2  $\Delta$  340.22).

USP Citalopram Related Compound C RS [3-(3-N,N-dimethylamino)-1-(4-fluorophenyl)-6-cyano-1(3H)-isobenzofuranone] (C20H19FN2O2  $\Delta$  338.22).

USP Citalopram Related Compound D RS [1-(4-fluorophenyl)-1-(3-(methylamino)propyl)-1,3-dihydroisobenzofuran-5-carbonitrile hydrochloride] (C19H19FN2O·HCl  $\Delta$  346.83).

USP Citalopram Related Compound E RS [1-(3-dimethylaminopropyl)-1-(4-fluorophenyl)-1,3-dihydrobenzofuran-5-carbonitrile-N-oxide] (C20H21FN2O2  $\Delta$  340.22).

USP Citalopram Related Compound F RS [dimethyl-(1-methyl-3,3-diphenylallyl)amine hydrochloride] (C18H21NHCl  $\Delta$  286.64).

USP Citalopram Related Compound G RS [1-(4'-fluorophenyl)-1-(3-dimethylaminopropyl)-5-chlorophthalane hydrobromide] (C19H21FNNOCl·HBr  $\Delta$  414.74).

USP Citalopram Related Compound H RS [1-(4'-fluorophenyl)-1-(3-dimethylaminopropyl)-5-bromophthalane hydrobromide] (C19H21FNNOBr·HBr  $\Delta$  459.1).

USP Citric Acid RS .

USP Clarithromycin RS .

USP Clarithromycin Identity RS. .

USP Clarithromycin Related Compound A RS [6,11-di-O-methylerythromycin A] (C39H71NO13  $\Delta$  762.00).

USP Clavam-2-Carboxylate Potassium RS .

USP Clavulanate Lithium RS .

USP Clemastine Fumarate RS .

USP Clidinium Bromide RS .

USP Clidinium Bromide Related Compound A RS  [3-hydroxy-1-methylquinuclidinium bromide] (C8H16BrNO  $\Delta$  222.13) .

USP Clindamycin Hydrochloride RS .

USP Clindamycin Palmitate Hydrochloride RS .

USP Clindamycin Phosphate RS .

USP Clioquinol RS .

USP Clobetasol Propionate RS .

USP Clobetasol Propionate Related Compound A RS  [9 $\alpha$ -fluoro-11 $\beta$ -hydroxy-16 $\beta$ -methyl 3-oxo-androsta-1,4-diene-17(R)-spiro-2'-[4'-chloro-5'-ethylfuran-3'(2'H)-one]] (C25H30ClFO4  $\Delta$  448.96) .

USP Clocortolone Pivalate RS .

USP Clofazimine RS .

USP Clofibrate RS .

USP Clomiphene Citrate RS .

USP Clomiphene Related Compound A RS  [(E,Z)-2-[4-(1,2-diphenylethoxy)phenoxy]-N,N-diethylethanamine hydrochloride] (C26H29NO·HCl  $\Delta$  407.98) .

USP Clomipramine Hydrochloride RS .

USP Clonazepam RS .

USP Clonazepam Related Compound A RS  [3-amino-4-(2-chlorophenyl)-6-nitrocarbostyryl] (C15H10ClN3O3  $\Delta$  315.72) .

USP Clonazepam Related Compound B RS  [2-amino-2'-chloro-5-nitrobenzophenone] (C13H9ClN2O3  $\Delta$  276.68) .

USP Clonazepam Related Compound C RS  [2-bromo-2'-(2-chlorobenzoyl)-4'-nitroacetanilide] .

USP Clonidine RS .

USP Clonidine Hydrochloride RS .

USP Clonidine Related Compound B RS  [2-[(E)-2,6-dichlorophenylimino]-1-(1-[(E)-2,6-dichlorophenylimino]-imidazolidin-1-yl)ethyl]imidazolidine] (C20H20Cl4N6  $\Delta$  486.23) .

USP Clopidogrel Bisulfate RS.

USP Clopidogrel Related Compound A RS  [(+)-(S)-(o-chlorophenyl)-6,7-dihydrothieno[3,2-c]pyridine-5(4H)-acetic acid].

USP Clopidogrel Related Compound B RS  [methyl ( $\pm$ )-(o-chlorophenyl)-4,5-dihydrothieno[2,3-c]pyridine-6(7H)-acetate, hydrochloride].

USP Metyrapone RS

USP Metyrosine RS

USP Mexiletine Hydrochloride RS .

USP Mezlocillin Sodium RS

USP Mibolerone RS

USP Miconazole RS

USP Miconazole Nitrate RS .

USP Powdered Milk Thistle Extract RS .

USP Milrinone RS

USP Milrinone Related Compound A RS [1,6-dihydro-2-methyl-6-oxo-(3,4'-bipyridine)-5-carboxamide] (C<sub>12</sub>H<sub>11</sub>N<sub>3</sub>O<sub>2</sub> ♦ 229.23) .

USP Mineral Oil RS .

USP Minocycline Hydrochloride RS .

USP Minoxidil RS

USP Mirtazapine RS .

Add the following:

▲USP Mirtazapine Related Compound A RS [1,2,3,4,10,14b-hexahydropyrazino[2,1-a]pyrido[2,3-c][2]benzazepine (C<sub>16</sub>H<sub>17</sub>N<sub>3</sub> ♦ 251.33). ▲USP32

USP Mitomycin RS

USP Mitotane RS

USP Mitoxantrone Hydrochloride RS .

USP Mitoxantrone System Suitability Mixture RS [9,10-antracenedione, 8-amino-1,4-dihydroxy-5-[2-[(2-hydroxyethyl)amino]ethyl]amino]-, hydrochloride] (C<sub>18</sub>H<sub>19</sub>N<sub>3</sub>O<sub>5</sub>·HCl ♦ 393.83) .

USP Modafinil RS.

USP Molindone Hydrochloride RS .

USP Mometasone Furoate RS

USP Monensin Sodium RS.

USP Monobenzone RS

USP Monoethanolamine RS

USP Monoglycerides RS .

USP Monostearyl Maleate RS

USP Morantel Tartrate RS .

USP Moricizine Hydrochloride RS

USP Morphine Sulfate RS .

USP Mupirocin RS

USP Mupirocin Lithium RS

USP Mycophenolate Mofetil RS.

USP Mycophenolate Mofetil Related Compound A RS [2-morpholinoethyl (E)-6-(1,3-dihydro-4,6-dihydroxy-7-methyl-3-oxo-5-isobenzofuranyl)-4-methyl-4-hexenoate] (C23H31NO7  $\Delta$  419.47).

USP Mycophenolate Mofetil Related Compound B RS [(RS)-7-hydroxy-5-methoxy-4-methyl-6-[2-(5-methyl-2-oxo-tetrahydrofuran-5-yl)ethyl]-3H-isobenzofuranyl-1-one] (C17H20O6  $\Delta$  320.34).

USP Nabumetone RS

USP Nabumetone Related Compound A RS [1-(6-methoxy-2-naphthyl)-but-1-en-3-one] (C15H14O2  $\Delta$  226.27).

USP Nadolol RS

USP Nafcillin Sodium RS .

USP Naftifine Hydrochloride RS .

USP Nalidixic Acid RS

USP Nalorphine Hydrochloride RS .

USP Naloxone RS .

USP Naltrexone RS .

USP Naltrexone Related Compound A RS [N-(3-butenyl)-noroxymorphone hydrochloride] (C20H23NO4·HCl  $\Delta$  377.87).

USP Nandrolone RS .

USP Nandrolone Decanoate RS

USP Nandrolone Phenpropionate RS .

USP Naphazoline Hydrochloride RS .

USP Naphthalene RS .

USP Naproxen RS

USP Naproxen Sodium RS .

USP Narasin RS.

USP Naratriptan Hydrochloride RS

USP Naratriptan Related Compound A RS [3-(1-methylpiperidin-4-yl)-1H-indole hydrochloride] (C14H18N2·HCl  $\Delta$  250.8).

USP Naratriptan Related Compound B RS [2-[3-(1-methyl-1,2,3,6-tetrahydropyridin-4-yl)-1H-indol-5-yl]ethanesulfonic acid methylamide oxalate] (C17H23N3O2S·C2H2O4  $\Delta$  423.5).

USP Naratriptan Resolution Mixture RS— A mixture of naratriptan hydrochloride with approximately 0.1% each of naratriptan related compound A [3-(1-methylpiperidin-4-yl)-1H-indole hydrochloride] and naratriptan related compound B [2-[3-(1-methyl-1,2,3,6-tetrahydropyridin-4-yl)-1H-indol-5-yl]ethanesulfonic acid methylamide oxalate].

USP Natamycin RS

USP Near-Infrared Calibrator RS.

USP Nefazodone Hydrochloride RS. 

USP Nefazodone Related Compound A RS  [1-(3-chloropropyl)-4-(chlorophenyl)piperazine] (C13H18Cl2N2  $\Delta$  273.20).

USP Nefazodone Related Compound B RS  [2-(3-(4-(chlorophenyl)-1-piperazinyl)propyl)-5-ethyl-2,4-dihydro-4-(2-phenoxyethyl)-3H-1,2,4-triazol-3-one] (C25H32ClN5O2  $\Delta$  470.01).

USP Neomycin Sulfate RS.

USP Neostigmine Bromide RS.

USP Neostigmine Methylsulfate RS.

USP Neotame RS.

USP Neotame Related Compound A RS  [N-[3,3-dimethylbutyl]-L-aspartyl]-L-phenylalanine].

USP Netilmicin Sulfate RS.

USP Nevirapine Anhydrous RS .

USP Nevirapine Hemihydrate RS .

USP Nevirapine Related Compound A RS  [5,11-dihydro-6H-11-ethyl-4-methyl-dipyrido[3,2-b:2',3'-e][1,4]diazepin-6-one] (C14H14N4O  $\Delta$  254.29).

USP Nevirapine Related Compound B RS  [5,11-dihydro-4-methyl-6H-dipyrido[3,2-b:2',3'-e][1,4]diazepin-6-one] (C12H10N4O  $\Delta$  226.23).

USP Niacin RS .

USP Niacinamide RS .

USP Nicotine Bitartrate Dihydrate RS .

USP Nifedipine RS .

USP Nifedipine Nitrophenylpyridine Analog RS  [dimethyl 4-(2-nitrophenyl)-2,6-dimethylpyridine-3,5-dicarboxylate] (C17H16N2O6  $\Delta$  344.33).

USP Nifedipine Nitrosophenylpyridine Analog RS  [dimethyl 4-(2-nitrosophenyl)-2,6-dimethylpyridine-3,5-dicarboxylate] (C17H16N2O5  $\Delta$  328.33).

USP Nimodipine RS .

USP Nimodipine Related Compound A RS  [(2-methoxyethyl-1-methylethyl)-2,6-dimethyl-4-(3-nitrophenyl)pyridine-3,5-dicarboxylate] (C21H24N2O7  $\Delta$  416.42).

USP Nitrofurantoin RS.

USP Nitrofurantoin Related Compound A RS  [N-(aminocarbonyl)-N-((5-nitro-2-furanyl)methylene)-amino]glycine].

USP Nitrofurazone RS .

USP Nitrofurazone Related Compound A RS  [5-nitro-2-furfuraldazine] (C10H6N4O6  $\Delta$  278.18).

USP Nitrofurfural Diacetate RS  (C9H9NO7  $\Delta$  243.17).

USP Nitrogen RS.

USP Diluted Nitroglycerin RS .

USP Nitrous Oxide RS.

USP Nizatidine RS .

USP Nonoxynol 9 RS .

USP Nordazepam RS  [7-chloro-1,3-dihydro-5-phenyl-2H-1,4-benzodiazepin-2-one] (C<sub>15</sub>H<sub>11</sub>CIN<sub>2</sub>O  $\Delta$  270.72).

USP Norepinephrine Bitartrate RS .

USP Norethindrone RS .

USP Norethindrone Acetate RS .

USP Norethynodrel RS .

USP Norfloxacin RS .

USP Norgestimate RS .

USP Norgestimate Related Compound A RS. .

USP Norgestimate Oxime Mixture RS  [mixture of syn-17-deacetyl norgestimate and anti-17-deacetyl norgestimate].

USP Norgestrel RS .

USP Noroxymorphone Hydrochloride RS .

USP Norphenylephrine Hydrochloride RS. .

USP Nortriptyline Hydrochloride RS .

USP Noscapine RS .

USP Novobiocin RS .

USP Nystatin RS .

USP Octinoxate RS  [octyl methoxycinnamate].

USP Octisalate RS  [octyl salicylate].

USP Octocrylene RS .

USP Octoxynol 9 RS .

USP Octyldodecanol RS .

USP Ofloxacin RS .

USP Ofloxacin Related Compound A RS  [9-fluoro-3-methyl-7-oxo-10-(piperazin-1-yl)-2,3-dihydro-7H-pyrido[1,2,3-de]-1,4-benzoxazine-6-carboxylic acid].

USP Oleic Acid RS. .

USP Oleoyl Polyoxylglycerides RS .

USP Oleyl Oleate RS. .

USP Omeprazole RS .

USP Omeprazole Magnesium RS. .

USP Omeprazole Related Compound A RS [(omeprazole sulfone, 5-methoxy-2-[[[(4-methoxy-3,5-dimethylpyridin-2-yl)methyl]sulfonyl]-1H-benzimidazole)] (C17H19N3O4S  $\diamond$  361.42  
 $\diamond$  CAS-88546-55-8).

USP Ondansetron Hydrochloride RS

USP Ondansetron Related Compound A RS [3[(dimethylamino)methyl]-1,2,3,9-tetrahydro-9-methyl-4H-carbazol-4-one].

USP Ondansetron Related Compound B RS [6,6'-methylene bis-[(1,2,3,9-tetrahydro-9-methyl-3-[(2-methyl-1H-imidazol-1-yl)-methyl]-4H-carbazol-4-one].

USP Ondansetron Related Compound C RS [1,2,3,9-tetrahydro-9-methyl-4H-carbazol-4-one].

USP Ondansetron Related Compound D RS [1,2,3,9-tetrahydro-9-methyl-3-methylene-4H-carbazol-4-one].

USP Ondansetron Resolution Mixture RS— Ondansetron hydrochloride having approximately 0.4% w/w of both ondansetron related compound A and 6,6'-methylene bis-[(1,2,3,9-tetrahydro-9-methyl-3-[(2-methyl-1H-imidazol-1-yl)-methyl]-4H-carbazol-4-one)].

USP Orphenadrine Citrate RS .

USP Oxacillin Sodium RS .

USP Oxandrolone RS

USP Oxandrolone Related Compound A RS [(7,8-didehydro-oxandrolone) or (17 $\beta$ -hydroxy-17 $\alpha$ -methyl-2-oxa-5 $\alpha$ -androst-7-en-3-one)].

USP Oxandrolone Related Compound B RS [(anhydro-oxandrolone) or (17 $\beta$ -17-dimethyl-2-oxa-18-nor-5 $\alpha$ -androstan-3-one)].

USP Oxandrolone Related Compound C RS [anhydro-oxandrolone (17,17-dimethyl-2-oxa-18-nor-5 $\alpha$ -androstan-3-one)].

USP Oxaprozin RS

USP Oxazepam RS

USP Oxfendazole RS

USP Oxprenolol Hydrochloride RS .

USP Oxtipryphline RS .

USP Oxybenzone RS

USP Oxybutynin Chloride RS

USP Oxybutynin Related Compound A RS [phenylcyclohexylglycolic acid] (C14H18O3  $\diamond$  234.30) .

USP Oxybutynin Related Compound B RS [methyl ester of phenylcyclohexylglycolic acid, or CHMME (cyclohexyl mandelic acid methyl ester)] .

USP Oxybutynin Related Compound C RS [methylethyl analog of oxybutynin chloride, or (4-(ethylmethylamino) but-2-ynyl ( $\pm$ ) 2-cyclohexyl-2-hydroxy-2-phenylacetate hydrochloride)] .

USP Oxycodone RS

USP Oxygen–Helium RS.

USP Oxymetazoline Hydrochloride RS

USP Oxymetholone RS

USP Oxymorphone RS

USP Oxyquinoline Sulfate RS .

USP Oxytetracycline RS .

USP Oxytocin RS .

USP Paclitaxel RS .

USP Paclitaxel Related Compound A RS  [cephalomannine] .

USP Paclitaxel Related Compound B RS  [10-deacetyl-7-epipaclitaxel] .

USP Paclitaxel Impurity Mixture RS— Mixture of paclitaxel and the following related compounds: propyl analog, cephalomannine, sec-butyl analog, n-butyl analog, benzyl analog, baccatin VI, pentyl analog, and 7-epipaclitaxel.

USP Padimate O RS .

USP Palmitic Acid RS .

USP Pamidronate Disodium RS. .

USP Pamoic Acid RS  (C<sub>23</sub>H<sub>16</sub>O<sub>6</sub>  $\Delta$  388.38) .

USP Pancreatin Amylase and Protease RS .

USP Pancreatin Lipase RS .

USP Pancuronium Bromide RS  [3 $\alpha$ ,17 $\beta$ -dihydroxy-2 $\beta$ ,16 $\beta$ -dipiperidinyl-5 $\alpha$ -androstane, 3,17-diacetate, dimethobromide] (C<sub>35</sub>H<sub>60</sub>Br<sub>2</sub>N<sub>2</sub>O<sub>4</sub>  $\Delta$  732.67).

USP Racemic Panthenol RS .

USP Pantolactone RS .

Add the following:

•USP Pantoprazole Sodium RS . • (RB 18-Jun-2008)

Add the following:

•USP Pantoprazole Related Compound A RS [5-(difluoromethoxy)-2-[(3,4-dimethoxy-2-pyridinyl)methyl]sulfonyl]-1H-benzimidazole] (C<sub>16</sub>H<sub>15</sub>F<sub>2</sub>N<sub>3</sub>O<sub>5</sub>S  $\Delta$  399.37). • (RB 18-Jun-2008)

Add the following:

•USP Pantoprazole Related Compound B RS [5-(difluoromethoxy)-2-[(3,4-dimethoxy-2-pyridinyl)methyl]thio]-1H-benzimidazole] (C<sub>16</sub>H<sub>15</sub>F<sub>2</sub>N<sub>3</sub>O<sub>3</sub>S  $\Delta$  367.37). • (RB 18-Jun-2008)

Add the following:

•USP Pantoprazole Related Compound C RS [5-(difluoromethoxy)-1H-benzimidazole-2-thiol] (C<sub>8</sub>H<sub>6</sub>F<sub>2</sub>N<sub>2</sub>O<sub>2</sub>S  $\Delta$  216.21). • (RB 18-Jun-2008)

Add the following:

•USP Pantoprazole Related Compound D and F Mixture RS— A mixture of 5-(difluoromethoxy)-2-[(RS)-[(3,4-dimethoxypyridin-2-yl)methyl]sulfinyl]-1-methyl-1H-benzimidazole and 6-(difluoromethoxy)-2-[(RS)-[(3,4-dimethoxypyridin-2-yl)methyl]sulfinyl]-1-methyl-1H-benzimidazole (C<sub>17</sub>H<sub>17</sub>F<sub>2</sub>N<sub>3</sub>O<sub>4</sub>S  $\Delta$  398.40). • (RB 18-Jun-2008)

Add the following:

•USP Pantoprazole Related Compound E RS— A mixture of the stereoisomers of 6,6'-bis(difluoromethoxy)-2,2'-bis[(3,4-dimethoxypyridin-2-yl)methyl]sulfinyl]-1H,1'H-5,5'-bibenzimidazolyl (C<sub>32</sub>H<sub>28</sub>F<sub>4</sub>N<sub>6</sub>O<sub>8</sub>S<sub>2</sub>  $\Delta$  764.74). • (RB 18-Jun-2008)

USP Papain RS .

USP Papaverine Hydrochloride RS .

USP Parachlorophenol RS. .

USP Paramethasone Acetate RS .

USP Paraffin RS.

USP Parbendazole RS

USP Paricalcitol RS.

USP Paricalcitol Solution RS.

USP Paromomycin Sulfate RS.

USP Paroxetine Hydrochloride RS .

USP Paroxetine Related Compound B RS [trans-4-phenyl-3-[(3,4-methylenedioxy)phenoxy]methylpiperidine hydrochloride].

USP Paroxetine Related Compound C RS [(+)-trans-paroxetine hydrochloride].

USP Paroxetine Related Compound E Mixture RS [paroxetine hydrochloride spiked with 1-methyl-4-(p-fluorophenyl)-1,2,3,6-tetrahydropyridine].

USP Paroxetine Related Compound F RS [trans-(−)-1-methyl-3-[1,3-benzodioxol-5-yloxy)methyl]-4-(fluorophenyl)piperidine] (C<sub>20</sub>H<sub>22</sub>FNO<sub>3</sub> 343.39).

USP Paroxetine Related Compound G RS [(±)trans-3-[(1,3-benzodioxol-5-yloxy)methyl]-4-(4'-fluorophenyl-4'-phenyl)piperidine hydrochloride] (C<sub>25</sub>H<sub>24</sub>FNO<sub>3</sub> 405.46).

USP Paroxetine System Suitability Mixture A RS —Mixture of approximately 1% paroxetine related compound A [piperidine, 3-[(1,3-benzodioxol-5-yloxy)methyl]-4-(4-methoxyphenyl)-hydrochloride (3 S-trans); and 1% of paroxetine related compound B [piperidine, 3-[(1,3-benzodioxol-5-yloxy)methyl]-4-phenyl-, hydrochloride (3 S-trans)]] in a matrix of paroxetine hydrochloride.

USP Parthenolide RS.

USP Particle Count RS (2 blanks and 2 suspensions).

USP Penbutolol Sulfate RS.

USP Penicillamine RS .

USP Penicillamine Disulfide RS (C<sub>10</sub>H<sub>20</sub>N<sub>2</sub>O<sub>4</sub>S<sub>2</sub>).

USP Penicillin G Benzathine RS.

USP Penicillin G Potassium RS.

USP Penicillin G Procaine RS.

USP Penicillin G Sodium RS.

USP Penicillin V RS .

USP Penicillin V Potassium RS.

USP Pentazocine RS .

USP Pentetic Acid RS .

USP Pentobarbital RS .

USP Pentoxyline RS .

USP Perflubron RS .

USP Pergolide Mesylate RS.

USP Pergolide Sulfoxide RS [(8 $\beta$ )-8-[(methylsulfinyl)methyl]-6-propyl-d-ergoline].

USP Perphenazine RS .

USP Perphenazine Sulfoxide RS

USP Phenacetin Melting Point RS

USP Phenazopyridine Hydrochloride RS .

USP Phendimetrazine Tartrate RS .

USP Phenelzine Sulfate RS .

USP Pheniramine Maleate RS .

USP Phenmetrazine Hydrochloride RS .

USP Phenobarbital RS

USP Phenol RS.

USP Phenoxybenzamine Hydrochloride RS .

USP Phenoxyethanol RS [2-phenoxyethanol] .

USP Phensuximide RS

USP Phentermine Hydrochloride RS .

USP Phentolamine Mesylate RS .

USP I-Phenylalanine RS

USP Phenylbenzimidazole Sulfonic Acid RS

USP Phenylbutazone RS

USP Phenylephrine Hydrochloride RS .

USP Phenylethyl Alcohol RS (C8H10O  $\Delta$  122.17).

USP 5-Phenylhydantoin RS

USP Phenylpropanediol RS [1-phenyl-1,2-propanediol] (C9H12O2  $\Delta$  152.19) .

USP Phenylpropanolamine Bitartrate RS .

USP Phenylpropanolamine Hydrochloride RS .

USP Phenyltoloxamine Citrate RS

USP Phenyltoloxamine Related Compound A RS [2-(2-benzylphenoxy)ethylmethylamine hydrochloride] (C16H19NO·HCl  $\Delta$  277.79) .

USP Phenytoin RS

USP Phenytoin Related Compound A RS [diphenylglycine] (C14H15NO2  $\Delta$  227.26) .

USP Phenytoin Related Compound B RS [diphenylhydantoic acid] (C15H14N2O3  $\Delta$  270.29) .

USP Phenytoin Sodium RS .

USP Cultured Rat Pheochromocytoma Reference Photomicrographs VRS.

USP Phosphated Riboflavin RS .

USP Physostigmine Salicylate RS .

USP Phytonadione RS .

USP Pilocarpine RS .

USP Pilocarpine Hydrochloride RS .

USP Pilocarpine Nitrate RS .

USP Pimozide RS .

USP Pindolol RS .

USP Piperacillin RS .

Add the following:

▲USP Piperazine Adipate RS. ▲USP32

Add the following:

▲USP Piperazine Dihydrochloride RS. ▲USP32

Add the following:

▲USP Piperazine Phosphate RS. ▲USP32

USP Piroxicam RS .

USP Plicamycin RS .

USP Polacrilex Resin RS .

USP Polacrilin Potassium RS .

USP Poloxamer Liquid RS. .

USP Poloxamer Solid RS. .

USP Poloxalene RS .

USP Polydimethylsiloxane RS .

USP High-Density Polyethylene RS .

Add the following:

▲USP Polyethylene Glycol 3350 RS. ▲USP32

USP Polyethylene Oxide RS .

USP Low-Density Polyethylene RS .

USP Polyethylene Terephthalate RS .

USP Polyethylene Terephthalate G RS .

USP Polyisobutylene RS.

USP Polymyxin B Sulfate RS .

USP Polyoxyl 20 Cetostearyl Ether RS.

USP Polyoxy 10 Oleyl Ether RS.

USP Polyoxy 10 Stearyl Ether RS.

USP Polyoxy 35 Castor Oil RS .

USP Polyoxy 40 Stearate RS

USP Polyoxy Lauryl Ether RS.

USP Polyoxy Oleate RS.

Add the following:

▲USP Polyvinyl Alcohol RS. ▲USP32

USP Posterior Pituitary RS .

USP Potassium Gluconate RS .

USP Potassium Guaiacolsulfonate RS

USP Potassium Perchlorate RS.

USP Potassium Sucrose Octasulfate RS [note—Sucrosofate Potassium is USAN] [ $\alpha$ -d-glucopyranoside, 1,3,4,6-tetra-O-sulfo- $\beta$ -d-fructofuranosyl, tetrakis (hydrogen sulfate), octapotassium salt, heptahydrate] (C12H14K8O3S8·7H<sub>2</sub>O  $\Delta$  1413.64  $\Delta$  CAS-76578-81-9). (anhydrous C12H14K8O3S8  $\Delta$  1287.53  $\Delta$  CAS-73264-44-5) .

USP Potassium Trichloroammineplatinate RS (Cl<sub>3</sub>H<sub>3</sub>KNPt  $\Delta$  357.58) .

USP Pralidoxime Chloride RS

USP Pramoxine Hydrochloride RS .

USP Pravastatin Sodium RS.

USP Pravastatin Related Compound A RS [3- $\alpha$ -hydroxyisocompactin] or [sodium (3R,5R)-3,5-dihydroxy-7-[(1S,2S,3S,8S,8aR)-3-hydroxy-2-methyl-8-[(2S)-2-methylbutanoyl]oxy]-1,2,3,7,8,8a-hexahydronephthalen-1-yl]heptanoate] (C<sub>23</sub>H<sub>35</sub>NaO<sub>7</sub>  $\Delta$  446.51) .

USP Pravastatin Related Compound B RS [6'-epi-pravastatin] or [sodium (3R,5R)-3,5-dihydroxy-7-[(1S,2S,6R,8S,8aR)-6-hydroxy-2-methyl-8-[(2S)-2-methylbutanoyl]oxy]-1,2,6,7,8,8a-hexahydronephthalen-1-yl]heptanoate] (C<sub>23</sub>H<sub>35</sub>NaO<sub>7</sub>  $\Delta$  446.51) .

USP Pravastatin 1,1,3,3-Tetramethylbutylamine RS.

USP Praziquantel RS

USP Praziquantel Related Compound A RS [2-benzoyl-1,2,3,6,7,11b-hexahydro-4H-pyrazino[2,1-a]isoquinolin-4-one] (C<sub>19</sub>H<sub>18</sub>N<sub>2</sub>O<sub>2</sub>  $\Delta$  306.37) .

USP Praziquantel Related Compound B RS [2-(cyclohexylcarbonyl)-2,3,6,7-tetrahydro-4H-pyrazino[2,1-a]isoquinolin-4-one] (C<sub>19</sub>H<sub>22</sub>N<sub>2</sub>O<sub>2</sub>  $\Delta$  310.40) .

USP Praziquantel Related Compound C RS [2-(N-formylhexahydrohippuroyl-1,2,3,4-tetrahydroisoquinolin-1-one] (C<sub>19</sub>H<sub>22</sub>N<sub>2</sub>O<sub>4</sub>  $\Delta$  342.39) .

USP Prazosin Hydrochloride RS .

USP Prednicarbate RS

USP Prednicarbate Related Compound A RS [1,2-dihydroprednicarbate] .

USP Prednicarbate Related Compound B RS [prednisolone-17-ethylcarbonate] .

USP Prednicarbate Related Compound C RS [prednisolone-21-propionate] .

USP Prednisolone RS

USP Prednisolone Acetate RS .

USP Prednisolone Hemisuccinate RS

USP Prednisolone Tebutate RS

USP Prednisone RS

USP Prednisone Tablets RS (Dissolution Calibrator, Disintegrating) .

USP Prilocaine Hydrochloride RS

USP Prilocaine RS.

USP Prilocaine Related Compound A RS [o-toluidine hydrochloride] (CH<sub>3</sub>C<sub>6</sub>H<sub>4</sub>NH<sub>2</sub>Cl  $\Delta$  143.62  $\Delta$  CAS-636-21-5) .

USP Prilocaine Related Compound B RS [(RS)-N-(4-methylphenyl)-2-(propylamino)propanamide] (C<sub>13</sub>H<sub>20</sub>N<sub>2</sub>O  $\Delta$  220.31) .

USP Primaquine Phosphate RS .

USP Primidone RS

USP Probenecid RS

USP Probucol RS

USP Probucol Related Compound A RS [2,2',6,6'-tetra-tert-butylidiphenoquinone] (C<sub>28</sub>H<sub>40</sub>O<sub>2</sub>  $\Delta$  408.63) .

USP Probucol Related Compound B RS [4,4'-(dithio)bis(2,6-di-tert-butylphenol)] (C<sub>28</sub>H<sub>42</sub>O<sub>2</sub>  $\Delta$  474.78) .

USP Probucol Related Compound C RS [4-[(3,5-di-tert-butyl-2-hydroxyphenylthio)isopropylidenethio]-2,6-di-tert-butylphenol] (C<sub>31</sub>H<sub>48</sub>O<sub>2</sub>S<sub>2</sub>  $\Delta$  516.86) .

USP Procainamide Hydrochloride RS .

USP Procaine Hydrochloride RS .

USP Procarbazine Hydrochloride RS .

USP Prochlorperazine Maleate RS .

USP Procyclidine Hydrochloride RS .

USP Progesterone RS

USP L-Proline RS .

USP Promazine Hydrochloride RS .

USP Promethazine Hydrochloride RS .

USP Propafenone Hydrochloride RS .

USP 2-Propanol RS.

USP Propantheline Bromide RS .

USP Propantheline Bromide Related Compound A RS [9-hydroxypropantheline bromide] (C<sub>23</sub>H<sub>30</sub>BrNO<sub>4</sub>  $\Delta$  464.39) .

USP Proparacaine Hydrochloride RS

USP Propofol RS

USP Propofol Related Compound A RS [3,3'-5,5'-tetraisopropylidiphenol].

USP Propofol Related Compound B RS [2,6-diisopropylbenzoquinone].

USP Propofol Related Compound C RS [2,6-diisopropylphenylisopropyl ether] (C14H22O  $\Delta$  206.32).

USP Propofol Resolution Mixture RS [propofol and 2-isopropyl-6-n-propylphenol].

USP Propoxycaaine Hydrochloride RS .

USP Propoxyphene Hydrochloride RS .

USP Propoxyphene Napsylate RS .

USP Propoxyphene Related Compound A RS [a-d-4-dimethylamino-1,2-diphenyl-3-methyl-2-butanol hydrochloride] (C19H25NO·HCl  $\Delta$  319.87).

USP Propoxyphene Related Compound B RS [ $\alpha$ -d-2-Acetoxy-4-dimethylamino-1,2-diphenyl-3-methylbutane] (C21H27NO2  $\Delta$  325.45).

USP Propranolol Hydrochloride RS .

USP Pyrvinium Pamoate RS .

USP Quazepam RS .

USP Quazepam Related Compound A RS [7-chloro-1-(2,2,2 trifluoroethyl)-5-(2-Fluorophenyl)-1,3-dihydro-2H-1,4-benzodiazepine-2-one].

USP Quercetin RS.

USP Quinapril Hydrochloride RS.

USP Quinapril Related Compound A RS [ethyl [3S-((2R\*), 3a, 11ab)]-1,3,4,6,11,11a-hexahydro-3-methyl-1,4-dioxo-a-(2-phenylethyl)-2H-pyrazino[1,2-b]isoquinoline-2-acetate] (C25H27N2O4  $\Delta$  419.49).

USP Quinapril Related Compound B RS [3-isoquinolinecarboxylic acid, 2-[2-[(1-carboxy-3-phenylpropyl)amino]-1-oxopropyl]-1,2,3,4-tetrahydro-, [3S-[2R\*(R\*)],3R\*]] (C23H26N2O5  $\Delta$  410.47).

USP Quinic Acid RS.

USP Quinidine Gluconate RS.

USP Quinidine Sulfate RS.

USP Quinine Sulfate RS.

USP Quininone RS (C20H22N2O2  $\Delta$  322.40).

USP 3-Quinuclidinyl Benzilate RS (C21H23NO3  $\Delta$  337.42).

USP Raloxifene Hydrochloride RS.

USP Ramipril RS .

USP Ramipril Related Compound A RS [(2S,3aS,6aS)-1-[(S)2-[(S)1-(methoxycarbonyl)-3-phenylpropyl]amino]-1-oxopropyl]-octahydrocyclopenta[b]pyrrole-2-carboxylic acid] (C22H30N2O5  $\Delta$  402.48).

USP Ramipril Related Compound B RS [(2S,3aS,6aS)-1-[(S)2-[(S)1-(methylethoxy)carbonyl-3-phenylpropyl]amino]-1-oxopropyl]-octahydrocyclopenta[b]pyrrole-2-carboxylic acid] (C24H34N2O5  $\Delta$  430.54).

USP Ramipril Related Compound C RS [(2S,3aS,6aS)-1-[(S)2-[(S)1-ethoxycarbonyl-3-cyclohexyl propyl]amino]-1-oxopropyl]-octahydrocyclopenta[b]pyrrole-2-carboxylic acid] (C23H38N2O5  $\Delta$  422.56).

USP Ramipril Related Compound D RS [ethyl (2S)2-[(3S,5aS,8aS, 9aS)-3-methyl-1,4-dioxodecahydro-1H-cyclopenta[e]pyrrolo[1,2-a]pyrazin-2-yl]-4-phenyl-butanoate] Ramipril Diketopiperazine (C23H30N2O4  $\Delta$  398.50).

USP Ranitidine Hydrochloride RS .

USP Ranitidine Related Compound A RS [5-[(2-aminoethyl)thio]methyl]-N,N-dimethyl-2-furanmethanamine, hemifumarate salt].

USP Ranitidine Related Compound B RS [N,N'-bis[2-[[5-[(dimethylamino)methyl]-2-furanyl]methyl]thio]ethyl]-2-nitro-1,1-ethenediamine].

USP Ranitidine Related Compound C RS [N-[2-[[5-[(dimethylamino)methyl]-2-furanyl]methyl]sulfinyl]ethyl]-N-methyl-2-nitro-1,1-ethenediamine].

USP Ranitidine Resolution Mixture RS— It is a mixture of ranitidine hydrochloride and four related impurities: ranitidine-N-oxide, ranitidine complex nitroacetamide, ranitidine diamine hemifumarate, and ranitidine amino alcohol hemifumarate.

Ranitidine-N-oxide: N,N-dimethyl[5-[[2-[(1-methylamino)-2-nitroethenyl]amino]ethyl]sulphanyl]methyl]furan-2-yl]methanamine N-oxide.

Ranitidine complex nitroacetamide: N-[2-[[5-[(dimethylamino)methyl]furan-2-yl]methyl]sulphanyl]ethyl]-2-nitroacetamide.

Ranitidine diamine hemifumarate (related compound A): [5-[(2-aminoethyl)thio]methyl]-N,N-dimethyl-2-furanmethanamine, hemifumarate salt].

Ranitidine amino alcohol hemifumarate: [5-[(dimethylamino)methyl]furan-2-yl]methanol.

USP Rauwolfia Serpentina RS .

USP Repaglinide RS .

USP Repaglinide Related Compound A RS [(S)-3-methyl-1-[2-(1-piperidinyl)phenyl]butylamine, N-acetyl-L-glutamate salt] (C16H26N2·C7H11NO5  $\Delta$  435.6).

USP Repaglinide Related Compound B RS [3-ethoxy-4-ethoxycarbonylphenylacetic acid] (C13H16O5  $\Delta$  252.27).

USP Repaglinide Related Compound C RS [(S)-2-ethoxy-4-[2-[[2-phenyl-1-[2-(1-piperidinyl)phenyl]ethyl]amino]-2-oxoethyl]benzoic acid] (C30H34N2O4  $\Delta$  486.61).

USP Reserpine RS .

USP Resorcinol RS .

USP Ribavirin RS .

USP Riboflavin RS .

USP Rifabutin RS .

USP Rifampin RS .

USP Rifampin Quinone RS .

USP Rimexolone RS .

USP Risperidone RS [3-[2-[4-(6-fluoro-1,2-benzisoxazol-3-yl)piperidino]ethyl]-6,7,8,9-tetrahydro-2-methyl-4H-pyrido[1,2-a]pyrimidin-4-one] (410.48  $\Delta$  CAS-106266-06-2).

USP Risperidone System Suitability Mixture RS —Contains risperidone and about 0.2% of each of the following:

Z-oxime-3-[2-[4-[(Z)-(2,4-difluorophenyl)(hydroxymino)methyl]piperidin-1-yl]ethyl]-2-methyl-6,7,8,9-tetrahydro-4H-pyrido[1,2-a]pyrimidin-4-one;

9-hydroxyrisperidone-(6RS)-3-[2-[4-(6-fluoro-1,2-benzisoxazol-3-yl)piperidin-1-yl]ethyl]-2,6-dimethyl-6,7,8,9-tetrahydro-4H-pyrido[1,2-a]pyrimidin-4-one;

6-methylrisperidone-(6RS)-3-[2-[4-(6-fluoro-1,2-benzisoxazol-3-yl)piperidin-1-yl]ethyl]-2,6-dimethyl-6,7,8,9-tetrahydro-4H-pyrido[1,2-a]pyrimidin-4-one.

USP Ritodrine Hydrochloride RS .

USP Ritonavir RS. .

USP Ritonavir Related Compounds Mixture RS.

USP Ropivacaine Hydrochloride RS. .

USP Ropivacaine Related Compound A RS [2,6-dimethylaniline hydrochloride] (C8H12ClN  $\Delta$  157.64.  $\Delta$  CAS-21436-98-6).

USP Ropivacaine Related Compound B RS [(R)-ropivacaine hydrochloride monohydrate; (R)-(-)-1-propylpiperidene-2-carboxylic acid (2,6-dimethylphenyl)-amide hydrochloride monohydrate] (C17H26N2O  $\Delta$  328.89).

USP Roxarsone RS .

USP Rutin RS

USP Saccharin RS

USP Saccharin Calcium RS .

USP Saccharin Sodium RS .

USP Salicylamide RS

USP Salicylic Acid RS

USP Salicylic Acid Related Compound A RS [4-hydroxybenzoic acid] (C7H6O3  $\Delta$  138.12  $\Delta$  CAS-99-96-7).

USP Salicylic Acid Related Compound B RS [4-hydroxyisophthalic acid] (C8H6O4  $\Delta$  182.13).

USP Salicylic Acid Tablets RS (Dissolution Calibrator, Non-disintegrating) .

USP Salsalate RS

USP Saquinavir Mesylate RS.

USP Saquinavir Related Compound A RS [N-tert-butyl-decahydro-2-[2(R)-hydroxy-4-phenyl-3(S)-[[N-(2-quinolylcarbonyl)-d-asparaginyl]amino]butyl]-4aS,8aS)-isoquinoline-3(S)-carboxamide] (C38H50N6O5  $\Delta$  670.84) .

USP Scopolamine Hydrobromide RS .

USP Scopoletin RS .

USP Secobarbital RS

USP Selegiline Hydrochloride RS .

USP Selenomethionine RS.

USP Sennosides RS .

USP I-Serine RS .

USP Sesame Oil Related Compound A RS.

USP Sesame Oil Related Compound B RS.

USP Sevoflurane RS

USP Sevoflurane Related Compound A RS [1,1,1,3,3-pentafluoroisopropenyl fluoromethyl ether] (C4H2F6O  $\Delta$  179.97) .

USP Sevoflurane Related Compound B RS [1,1,1,3,3,3-hexafluoro-2-methoxy-propane].

USP Sevoflurane Related Compound C RS [1,1,1,3,3,3-hexafluoro-2-propanol].

USP Sevomethyl Ether RS [1,1,1,3,3,3-hexafluoro-2-methoxy-propane].

USP Silver Sulfadiazine RS

USP Silybin RS .

USP Silydianin RS .

USP Simethicone RS

USP Simvastatin RS

USP Sincalide RS.

USP Sisomicin Sulfate RS .

USP  $\beta$ -Sitosterol RS .

USP Human Fibroblast-Derived Temporary Skin Substitute Reference Photomicrographs VRS.

USP Sodium Ascorbate RS .

USP Sodium Benzoate RS.

USP Sodium Bromide RS.

USP Sodium Butyrate RS .

USP Sodium Fluoride RS .

USP Sodium Lactate RS .

USP Sodium Nitroprusside RS .

USP Sodium Propionate RS .

USP Sodium Salicylate RS.

USP Sodium Starch Glycolate Type A RS .

USP Sodium Starch Glycolate Type B RS .

USP Sodium Stearyl Fumarate RS .

USP Somatropin RS .

USP 1,4-Sorbitan RS (C6H12O5  $\Delta$  164.16) .

USP Sorbitol RS .

USP Sotalol Hydrochloride RS .

USP Sotalol Related Compound A RS [N[(4-[(1-methylethyl)amino]acetyl]phenyl)methanesulfonamide monohydrochloride] (C12H18N2O3S·HCl  $\Delta$  306.81) .USP Sotalol Related Compound B RS [N-(4-formylphenyl)methanesulfonamide] (C8H9NO3S  $\Delta$  199.23) .USP Sotalol Related Compound C RS [N-[4-{2-[(1-methylethyl)amino]ethyl}phenyl)methanesulfonamide monohydrochloride] (C12H20N2O2S·HCl  $\Delta$  292.83) .

Add the following:

▲USP Defatted Powdered Soy RS ▲USP32

USP Spectinomycin Hydrochloride RS .

USP Spironolactone RS .

USP Squalane RS .

USP Stanozolol RS .

USP Stavudine RS .

USP Stavudine System Suitability Mixture RS —It is a mixture of stavudine and the following related compounds: thymidine, thymine, alpha-stavudine, and xylo-thymidine.

USP Stearic Acid RS .

USP Stearyl Alcohol RS .

USP Stearyl Polyoxylglycerides RS .

USP Powdered St. John's Wort Extract RS.

USP Streptomycin Sulfate RS .

USP Succinylcholine Chloride RS .

USP Succinylmonocholine Chloride RS .

USP Sucralose RS .

USP Sucrose RS .

USP Sufentanil Citrate RS .

#### ◀ 16 ▶ AUTOMATED METHODS OF ANALYSIS

Where a sufficiently large number of similar units are to be subjected routinely to the same type of examination, automated methods of analysis may be far more efficient and precise than manual methods. Such automated methods have been found especially useful in testing the content uniformity of tablets and capsules and in facilitating methods requiring precisely controlled experimental conditions. Many manufacturing establishments, as well as the laboratories of regulatory agencies, have found it convenient to utilize automated methods as alternatives to Pharmacopeial methods (see Procedures under Tests and Assays in the General Notices and Requirements). In addition, the detection system and calculation of results for automated methods are often computerized.

Before an automated method for testing an article is adopted as an alternative, it is advisable to ascertain that the results obtained by the automated method are equivalent in accuracy and precision to those obtained by the prescribed Pharmacopeial method, bearing in mind the further principle stated in the General Notices and Requirements that "where a difference appears, or in the event of dispute, only the result obtained by the procedure given in this Pharmacopeia is conclusive."

It is necessary to monitor the performance of the automated analytical system continually by assaying standard preparations of known composition frequently interspersed among the test preparations. Where immiscible solvents are employed in the automated apparatus for rapid extractions, they are often separated for analysis before complete extraction is attained, and the chemical reactions utilized in automated methods rarely are stoichiometric. Both the accuracy and the precision of the determinations depend upon precise adjustment of the equipment, so maintained that all standard and test preparations are exposed to identical physical and chemical manipulations for identical time intervals. Excessive variability in the response of the standard preparations indicates that the analytical system is malfunctioning and that the test results are therefore invalid. However, where automated systems are shown to operate reliably, the precision of the automated method may surpass that of the manual procedure employing the same basic chemistry.

Many of the manual methods given in this Pharmacopeia can be adapted for use in automated equipment incorporating either discrete analyzers or continuous flow systems and operating under a variety of conditions. On the other hand, an analytical scheme devised for a particular automated system may not be readily transposable for use either in a manual procedure or in other types of automated equipment.

The apparatus required for manual methods is, in general, less complicated than the apparatus of automated systems, even those systems used for the direct automated measurement of a single analyte (i.e., the substance being determined or analyzed for) in a binary mixture. However, because of their versatility, automated systems designed for the rapid determination of a specified substance often can be readily modified by the addition of suitable modules and accessories to permit the determination of one or more additional substances in a dosage form. Such extended systems have been utilized, for example, in the automated analysis of articles containing both estrogens and progestogens.

The accompanying pertinent diagrams represent examples of automated methods. Diagrams for official methods are reproduced here rather than in the individual monographs. The descriptions of the procedural details in these methods exemplify the general approach in automated analysis applicable to dosage forms. It should be noted that the diagrams, with many minutiae, are an indispensable part of the directions for conducting the analysis.

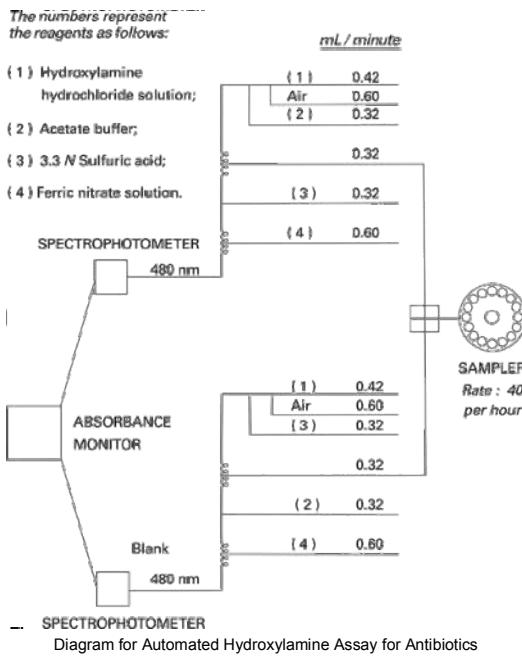

#### DIAGRAMS

The diagrams shown below are arranged in alphabetic order by the name of the drug first mentioned, where the diagram is for a procedure for a specific article. Where there is no procedure in this chapter for a particular diagram, reference is to be made to the named monograph.

#### ANTIBIOTICS—HYDROXYLAMINE ASSAY

The following procedure is applicable for the assay of those Pharmacopeial antibiotics, such as cephalosporins and penicillins, that possess the beta-lactam structure.

Apparatus— Automatic analyzer consisting of (1) a liquid sampler, (2) a proportioning pump, (3) suitable spectrophotometers equipped with matched flow cells and analysis capability at 480 nm, (4) a means of recording spectrophotometric readings, and/or computer for data retrieval and calculation, and (5) a manifold consisting of the components illustrated in the accompanying pertinent [diagram](#).

## Diagram for Automated Hydroxylamine Assay for Antibiotics

## Reagents—

Hydroxylamine Hydrochloride Solution— Dissolve 20 g of hydroxylamine hydrochloride in 5 mL of polyoxyethylene (23) lauryl ether solution (1 in 1000), and add water to make 1000 mL.

Acetate Buffer— Dissolve 173 g of sodium hydroxide and 20.6 g of sodium acetate in water to make 1000 mL. Dilute 75 mL of this solution with water to 500 mL, and mix.

Ferric Nitrate Solution— Suspend 233 g of ferric nitrate in about 600 mL of water, add 2.8 mL of sulfuric acid, stir until the ferric nitrate is dissolved, add 1 mL of polyoxyethylene (23) lauryl ether, dilute with water to 1000 mL, and mix.

USP Reference Standards (11)—Use the USP Reference Standard as directed in the individual monograph.

Standard Preparation— Unless otherwise directed in the individual monograph, dissolve an accurately weighed quantity of the USP Reference Standard in water, and quantitatively dilute with water to obtain a solution having a known concentration of about 1 mg per mL.

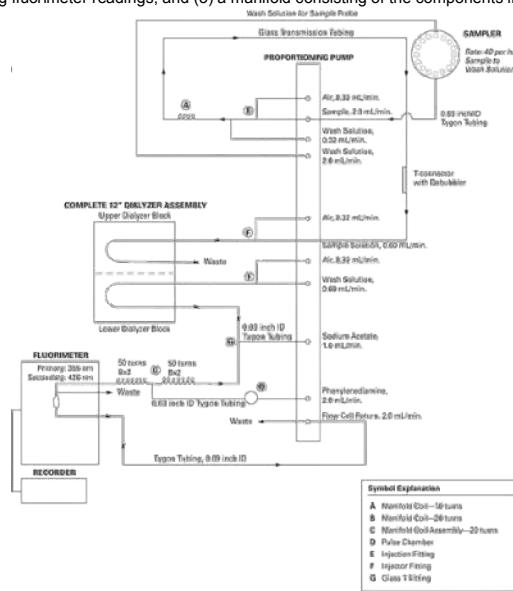

**Assay Preparation**— Unless otherwise directed in the individual monograph, using the specimen under test, prepare as directed under Standard Preparation.

Procedure— With the sample line pumping water, the other lines pumping their respective reagents, and the spectrophotometer set at 480 nm, standardize the system until a steady absorbance baseline has been established. Transfer portions of the Standard Preparation and the Assay Preparation to sampler cups, and place in the sampler. Start the sampler, and conduct determinations of the Standard Preparation and the Assay Preparation typically at the rate of 40 per hour, using a ratio of about 2:1 for sample and wash time. Calculate the potency by the formula given in the individual monograph, in which C is the concentration, in mg per mL, of USP Reference Standard in the Standard Preparation; P is the potency, in  $\mu$ g per mg, of the USP Reference Standard; and AU and AS are the absorbances, corrected for the absorbances of the respective blanks, of the solutions from the Assay Preparation and the Standard Preparation, respectively.

#### ASSAY FOR ASCORBIC ACID

The following procedure is applicable for the assay of ascorbic acid in Pharmacopeial multivitamin-minerals combination products (solid and liquid dosage forms) that contain components that interfere in other methods of assay.

Apparatus— Automatic analyzer consisting of (1) a liquid sampler; (2) a proportioning pump; (3) a suitable fluorimeter equipped with a flow cell and filters: primary—335 nm, and secondary—426 nm; (4) a means of recording fluorimeter readings; and (5) a manifold consisting of the components illustrated in the accompanying pertinent diagram.

### Diagram for Automated Ascorbic Acid

## Reagents—

Extracting Solution— Dissolve 600 g of metaphosphoric acid in 1200 mL of water. Add 400 mL of glacial acetic acid, dilute with water to 2000 mL, and mix.

Dilute Extracting Solution— Dissolve 60 g of metaphosphoric acid in 1200 mL of water. Add 160 mL of glacial acetic acid, dilute with water to 2000 mL, and mix.

**Surfactant Solution**— Prepare a 30% solution of polyoxyethylene (23) lauryl ether by melting 150 g in a container on a steam bath and slowly adding approximately 250 mL of water with continuous stirring. Cool and dilute with water to make 500 mL.

Wash Solution— Add 1 mL of Surfactant Solution to 3000 mL of Dilute Extracting Solution, and mix.

Carbon Extraction Solution— Dissolve 60 g of metaphosphoric acid in 1200 mL of water. Add 160 mL of glacial acetic acid, and mix. Add 33 g of activated charcoal powder, mix, and dilute with water to 2000 mL. Continually mix the solution at a rate that maintains homogeneity.

**Sodium Acetate Solution**— Dissolve 500 g of sodium acetate trihydrate in water to make 1000 mL, mix, and filter.

Phenylenediamine Solution— Dissolve 200 mg of o-phenylenediamine dihydrochloride in water to make 1000 mL, and mix. Prepare fresh daily.

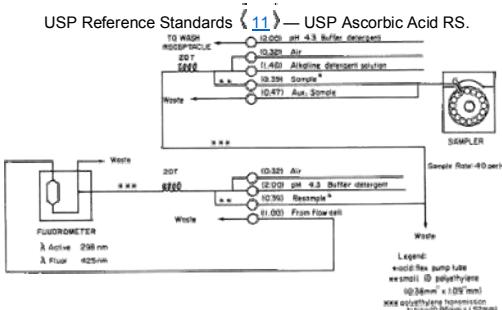

Diagram for Automated Aspirin Determinative Step of the Dissolution Test for Aspirin, Alumina, and Magnesium Oxide Tablets

Standard Stock Solution— Dissolve an accurately weighed quantity of USP Ascorbic Acid RS in Dilute Extracting Solution to obtain a solution having a known concentration of about 0.1 mg per ml.

Standard Preparations— Transfer 10.0, 20.0, 30.0, 40.0, and 50.0 mL of Standard Stock Solution to separate 100-mL volumetric flasks, dilute the contents of each flask with Carbon Extracting Solution to volume, mix, and filter to obtain Standard Preparations A, B, C, D, and E having known concentrations of 10 µg, 20 µg, 30 µg, 40 µg, and 50 µg of USP Ascorbic Acid RS per mL, respectively.

### Assay Preparation—

For Liquid Preparations— Transfer an accurately measured volume of the liquid preparation, equivalent to 150 mg of ascorbic acid, to a 100-mL volumetric flask. Add 10 mL of Extracting Solution and 6 mL of glacial acetic acid. Dilute with water to volume, and mix. Transfer 2.0 mL of this solution to a 100-mL volumetric flask, dilute with Carbon Extracting Solution to volume, mix, and filter.

For Tablet Preparations— Weigh and finely powder not fewer than 20 Tablets. Transfer an accurately weighed quantity of the powder, equivalent to about 250 mg of ascorbic acid, to a 250-mL volumetric flask. Add 25 mL of Extracting Solution, 15 mL of glacial acetic acid, and about 100 mL of water, and swirl to mix. Heat for 15 minutes in a 70° water bath, swirling after about 7 minutes. Cool, and dilute with water to volume. Transfer 2.0 mL of this solution to a 100-mL volumetric flask, dilute with Carbon Extracting Solution to volume, mix, and filter.

For Capsule Preparations— Empty the contents, if necessary by cutting open with a sharp blade, of not fewer than 20 Capsules in a suitable container, and mix thoroughly. Transfer a portion of the capsule contents, equivalent to about 250 mg of ascorbic acid, to a 250-mL volumetric flask, and proceed as directed for Tablets above, beginning with "Add 25 mL of ."

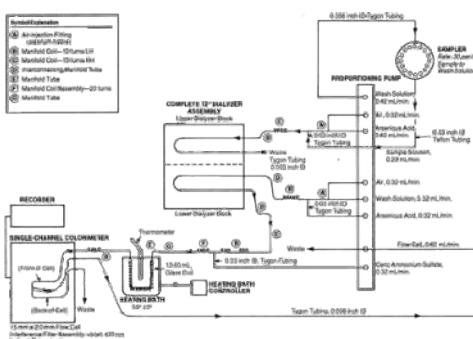

Procedure— With the sample line pumping the Wash Solution, the other lines pumping their respective reagents, and the fluorimeter equipped with proper filters, standardize the system by pumping until a steady baseline has been established. Transfer portions of the Standard Preparations and the Assay Preparation to sample cups, and place in the sampler. Start the sampler, and conduct determinations of each Standard Preparation and the Assay Preparation at the rate of 40 per hour, using a ratio of about 2:1 for sample and wash time. Derive a standard response line by plotting the respective Standard Preparation concentration (10.0, 20.0, 30.0, 40.0, and 50.0  $\mu\text{g}$  per mL) versus transmittance. From the measured transmittance and the standard response line, determine the ascorbic acid concentration,  $C$ , in  $\mu\text{g}$  per mL, of the Assay Preparation. Calculate the quantity, in mg, of  $\text{C}_6\text{H}_8\text{O}_6$  in the portion of liquids, tablets, or capsule contents taken by the appropriate formula:

For Liquids: 5C<sub>1</sub>V in which V is the volume, in mL, of liquid preparation taken to prepare the Assay Preparation.

For Tablets or Capsules: 12.5G

#### ASSAY FOR IODIDE

Apparatus— Automatic analyzer consisting of (1) a liquid sampler, (2) a proportioning pump, (3) a heating bath, (4) a suitable colorimeter equipped with a 2.0- × 50-mm flow cell and analysis capability at 420 nm, (5) a means of recording colorimetric readings, and (6) a manifold consisting of the components illustrated in the accompanying pertinent *diagram*.

### Diagram for Automated Iodide Assay

### Reagents—

Acetic Acid Carrier Solution— Transfer 3.0 mL of glacial acetic acid to a 2000-mL volumetric flask containing about 800 mL of water. Add 2 mL of polyoxyethylene (23) lauryl ether, and dilute with water to volume.

**Surfactant Solution**— Prepare a 30% solution of polyoxyethylene (23) lauryl ether by melting 150 g in a container on a steam bath and slowly adding approximately 250 mL of water with continuous stirring. Cool, and dilute with water to make 500 mL.

Arsenious Acid Solution— Transfer 19.6 g of arsenic trioxide and 14.0 g of sodium hydroxide to a 2000-mL volumetric flask. Add about 150 mL of water, and dissolve with stirring. Dilute with water to a volume of about 800 mL, and add 66 mL of sulfuric acid. Cool to room temperature. Transfer 50.0 g of sodium chloride to the solution, and mix to dissolve. Add 2 mL of Surfactant Solution, dilute with water to volume, mix, and filter.

Ceric Ammonium Sulfate Solution— Transfer 12.65 g of ceric ammonium sulfate to a 1000-mL volumetric flask. Add about 700 mL of water followed by 100 mL of sulfuric acid, swirling to mix. Heat to dissolve, and cool to room temperature. Add 1 mL of Surfactant Solution, dilute with water to volume, mix, and filter.

3% Acetic Acid Solution— Transfer 30 mL of glacial acetic acid to a 1000-mL volumetric flask containing about 300 mL of water. Dilute with water to volume, and mix.

#### Standard Preparations—

Standard Stock Solution— Transfer an accurately weighed quantity of 1.3080 g of potassium iodide, previously dried for 24 hours at 105°, to a 1000-mL volumetric flask. Dilute with water to volume, and mix to obtain a solution having an iodide concentration of 1000 µg per mL.

Intermediate Standard Solution— Quantitatively dilute a suitable volume of Standard Stock Solution with water to obtain a solution having an iodide concentration of 1 µg per mL.

Working Standard Preparations— Transfer 2.0, 4.0, 6.0, 8.0, and 10.0 mL of Intermediate Standard Solution to separate 100-mL volumetric flasks. Add 5 mL of 3% Acetic Acid Solution. Dilute the contents of each flask with water to volume, and mix to obtain Standard Preparations A, B, C, D, and E having known iodide concentrations of about 0.02 µg per mL, 0.04 µg per mL, 0.06 µg per mL, 0.08 µg per mL, and 0.1 µg per mL, respectively.

#### Assay Preparation—

For Liquid Preparations— Transfer an accurately measured volume of the liquid preparation, equivalent to 16 µg of iodide, to a 200-mL volumetric flask. Add 10 mL of 3% Acetic Acid Solution to dissolve, dilute with deionized water to volume, mix, and filter. Transfer 10.0 mL of this solution to a 100-mL volumetric flask, add 5.0 mL of 3% Acetic Acid Solution, dilute with deionized water to volume, mix, and filter to obtain a solution having an iodide concentration of about 0.08 µg per mL.

For Tablet Preparations— Weigh and finely powder not fewer than 20 Tablets. Transfer an accurately weighed quantity of the powder, equivalent to about 250 µg of iodide, to a 250-mL volumetric flask. Add 100 mL of 1 N hydrochloric acid, and mix with the aid of sonication for 30 minutes. Dilute with water to volume, mix, and filter. Transfer 8.0 mL of the filtered solution to a 100-mL volumetric flask, add 5 mL of 3% Acetic Acid Solution, dilute with water to volume, and mix to obtain a solution having an iodide concentration of about 0.08 µg per mL.

For Capsule Preparations— Empty the contents, if necessary by cutting open with a sharp blade, of not fewer than 20 Capsules into a suitable container, and mix thoroughly. Transfer a portion of the capsule contents, equivalent to about 250 µg of iodide, to a 250-mL volumetric flask and proceed as directed for Tablets above, beginning with "Add 100 mL of ."

Procedure— With the sample line pumping the Acetic Acid Carrier Solution, the other lines pumping their respective reagents, and the colorimeter equipped with 420-nm filters, standardize the system until a steady baseline has been established. Transfer portions of the Standard Preparations and the Assay Preparation to the sampler cups, and place in the sampler. Start the sampler, and conduct determinations of each Standard Preparation and the Assay Preparation at the rate of 30 per hour, using a ratio of about 1:4 for sample and wash time. Derive a standard response line by plotting the respective Standard Preparation concentration (0.02, 0.04, 0.06, 0.08, and 0.10 µg per mL) versus absorbance. [note—This is an indirect absorbance relationship: the greater the iodide amount, the less the absorbance.] From the measured transmittance and the standard response line, determine the iodide concentration, C, in µg per mL, of the Assay Preparation. Calculate the quantity, in µg, of iodide in the portion of liquids, tablets, or capsules contents taken by the formula:

For Liquids:  $2000C/V$  in which V is the volume, in mL, of the liquid preparation taken to prepare the Assay Preparation.

For Tablets and Capsules: 3125C.

#### CONTENT UNIFORMITY OF NITROGLYCERIN TABLETS

This is not to be considered as the official method. It is detailed here for further illustration of descriptions of automated methods.

Apparatus— Automatic analyzer consisting of (1) a liquid sampler, (2) a proportioning pump, (3) a heating bath, (4) a suitable spectrophotometer equipped with a 5-mm flow cell and analysis capability at 545 nm, (5) a means of recording spectrophotometric readings, and (6) a manifold consisting of the components illustrated in the accompanying pertinent diagram.

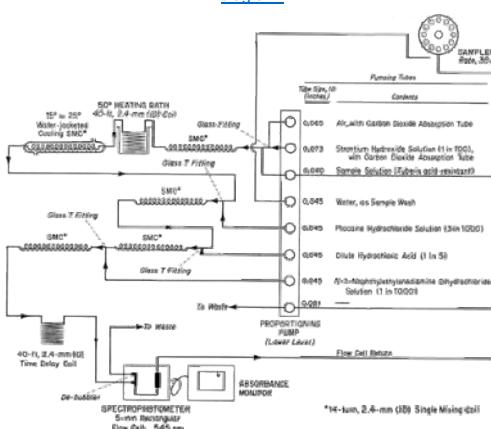

Diagram for Automated Assay for Nitroglycerin Tablets

#### Reagents—

1 Percent Strontium Hydroxide Solution— Dissolve 20.0 g of strontium hydroxide [Sr(OH)<sub>2</sub>·8H<sub>2</sub>O] in 1800 mL of carbon dioxide-free water, heating if necessary. Cool to room temperature, dilute with carbon dioxide-free water to 2000 mL, and mix. Allow to stand overnight, and filter. Store the clear solution in tightly closed containers, protected from carbon dioxide.

0.3 Percent Procaine Hydrochloride Solution— Dissolve 3.0 g of procaine hydrochloride in water to make 1000 mL.

0.1 Percent N-(1-Naphthyl)ethylenediamine Dihydrochloride Solution— Dissolve 1.0 g of N-(1-naphthyl)ethylenediamine dihydrochloride in water to make 1000 mL. Prepare fresh each week.

Standard Preparation— Dissolve an accurately weighed portion of 10% nitroglycerin-beta lactose absorbate, previously standardized, in water, and dilute quantitatively and stepwise with water to obtain a solution having a known concentration of about 30 µg per mL.

Test Preparation— Dissolve 1 Nitroglycerin Tablet in water to obtain a solution having a concentration of about 30 µg of nitroglycerin per mL.

Procedure— With the sample line pumping water, the other lines pumping their respective reagents, and the spectrophotometer set at 545 nm, standardize the system by pumping until a steady absorbance baseline has been established. Transfer portions of the Standard Preparation and the Test Preparation to sampler cups, and place in the sampler. Start the sampler, and conduct determinations of the Standard Preparation and the Test Preparation at a rate of 30 per hour, using a ratio of 1:1 for sample and wash time. First, run two standards, discarding the first value, then continue the run using one standard after each five samples, recording the absorbance values. Calculate the quantity, in mg, of C<sub>3</sub>H<sub>5</sub>N<sub>3</sub>O<sub>9</sub> in the Tablet taken by the formula:

in which T is the labeled quantity, in mg, of nitroglycerin in the Tablet; D is the concentration, in  $\mu\text{g}$  per mL, of nitroglycerin in the solution from the Tablet, based on the labeled quantity per Tablet and the extent of dilution; C is the concentration, in  $\mu\text{g}$  per mL, of nitroglycerin in the Standard Preparation; AU is the absorbance of the Test Preparation; and AS is the average of the absorbances of the two Standard Preparations that bracket the Test Preparation.

Temperature reading devices suitable for Pharmacopeial tests conform to specifications that are traceable to a NIST standard. Temperature reading devices may be of the liquid-in-glass type or an analog or digital temperature indicator type, such as a resistance temperature device, thermistor, or thermocouple.

An analog or digital temperature indicator consists of a temperature probe, which houses a sensor. The probe is attached to a meter capable of translating a signal in ohms or millivolts into a temperature reading. The temperature probe portion of the analog or digital temperature indicator that is submerged in the medium whose temperature is being measured must be made of inert material. Standardization of analog and digital temperature indicator devices is performed on an established testing frequency with a temperature standard traceable to NIST. In the selection of a temperature reading device, careful consideration of the condition under which it is to be used is essential.

Liquid-in-glass thermometers may be standardized for total immersion, partial immersion, or full immersion. Insofar as practicable, each thermometer should be employed according to the condition of immersion under which it was standardized. Standardization of thermometers is performed on an established testing frequency with a temperature standard traceable to NIST. Refer to the current issue of ASTM standards E1. Standardization of liquid-in-glass thermometers for total immersion involves immersion of the thermometer to the top of the liquid column, with the remainder of the stem and the upper expansion chamber exposed to ambient temperature. Standardization for partial immersion involves immersion of the thermometer to the indicated immersion line etched on the front of the thermometer, with the remainder of the stem exposed to ambient temperature. Standardization for full immersion involves immersion of the entire thermometer, with no portion of the stem exposed to ambient temperature. For use under other conditions of immersion, an emergent stem correction is necessary to obtain correct temperature readings.

Auxiliary Information— Please [check for your question in the FAQs](#) before contacting USP.

### 31 VOLUMETRIC APPARATUS

Most of the volumetric apparatus available in the United States is calibrated at 20°, although the temperatures generally prevailing in laboratories more nearly approach 25°. To minimize volumetric error, the temperature should be the same for the volumetric apparatus, the material being prepared, the solvents being used to prepare the volumetric solutions, the area in which they are prepared, and the final volume adjustment.

**Use**— To attain the degree of precision required in many Pharmacopeial assays involving volumetric measurements and directing that a quantity be "accurately measured," the apparatus must be chosen and used with care. A buret should be of such size that the titrant volume represents not less than 30% of the nominal volume. Where less than 10 mL of titrant is to be measured, a 10-mL buret or a microburet generally is required.

The design of volumetric apparatus is an important factor in assuring accuracy. For example, the length of the graduated portions of graduated cylinders should be not less than five times the inside diameter, and the tips of burets and pipets should restrict the outflow rate to not more than 500 µL per second.

**Standards of Accuracy**— The capacity tolerances for volumetric flasks, transfer pipets, and burets are those accepted by the National Institute of Standards and Technology (Class A),<sup>1</sup> as indicated in the accompanying tables. Use Class A volumetric apparatus unless otherwise specified in the individual monograph. For plastic volumetric apparatus the accepted capacity tolerances are Class B.<sup>2</sup>

The capacity tolerances for measuring (i.e., "graduated") pipets of up to and including 10-mL capacity are somewhat larger than those for the corresponding sizes of transfer pipets, namely, 10, 20, and 30 µL for the 2-, 5-, and 10-mL sizes, respectively.

Transfer and measuring pipets calibrated "to deliver" should be drained in a vertical position and then touched against the wall of the receiving vessel to drain the tips. Volume readings on burets should be estimated to the nearest 0.01 mL for 25- and 50-mL burets, and to the nearest 0.005 mL for 5- and 10-mL burets. Pipets calibrated "to contain" are called for in special cases, generally for measuring viscous fluids like syrups; however, a volumetric flask may be substituted for a "to contain" pipet. In such cases, the pipet or flask should be washed clean, after draining, and the washings added to the measured portion.

#### Volumetric Flasks

Pharmacopeial Forum: Volume No. 32(6) Page 1780

### 41 WEIGHTS AND BALANCES

The intent of this section is to bring the requirements for weights into conformity with American National Standard ANSI/ASTM E617, "Laboratory Weights and Precision Mass Standards." This standard is incorporated by reference and should be consulted for full descriptions and information on the tolerances and construction of weights.<sup>1</sup>

Pharmacopeial tests and assays require balances that vary in capacity, sensitivity, and reproducibility. Unless otherwise specified, when substances are to be "accurately weighed" for

say, the weighing is to be performed with a weighing device whose measurement uncertainty (random plus systematic error) does not exceed 0.1% of the reading. Measurement uncertainty is satisfactory if three times the standard deviation of not less than ten replicate weighings divided by the amount weighed, does not exceed 0.001. Unless otherwise specified, for titrimetric limits tests, the weighing shall be performed to provide the number of significant figures in the weight of the analyte that corresponds to the number of significant figures in the concentration of the titrant.

The class designations below are in order of increasing tolerances.

Class 1.1 weights are used for calibration of low-capacity, high-sensitivity balances. They are available in various denominations from 1 to 500 mg. The tolerance for any denomination in this class is 5 µg. They are recommended for calibration of balances using optical or electrical methods for accurately weighing quantities below 20 mg.

Class 1 weights are designated as high-precision standards for calibration. They may be used for weighing accurately quantities below 20 mg. (For weights of 10 g or less, the requirements of class 1 are met by USP XXI class M.)

Class 2 weights are used as working standards for calibration, built-in weights for analytical balances, and laboratory weights for routine analytical work. (The requirements of class 2 are met by USP XXI class S.)<sup>2</sup>

Class 3 and class 4 weights are used with moderate-precision laboratory balances. (Class 3 requirements are met by USP XXI class S-1; class 4 requirements are met by USP XXI class P.)<sup>2</sup>

A weight class is chosen so that the tolerance of the weights used does not exceed 0.1% of the amount weighed. Generally, class 2 may be used for quantities greater than 20 mg, class 3 for quantities of greater than 50 mg, and class 4 for quantities of greater than 100 mg. Weights should be calibrated periodically, preferably against an absolute standard weight.

1 Copies of ASTM Standard E 617-81 (Reapproved 1985) may be obtained from the American Society for Testing and Materials, 1916 Race Street, Philadelphia, PA 19103.

2 Note that the designations S and P no longer designate weight classes but rather weight grades, that is, design limitations such as range of density of materials, surface area, surface finish, corrosion resistance, and hardness.

#### 51 ANTIMICROBIAL EFFECTIVENESS TESTING

Antimicrobial preservatives are substances added to nonsterile dosage forms to protect them from microbiological growth or from microorganisms that are introduced inadvertently during or subsequent to the manufacturing process. In the case of sterile articles packaged in multiple-dose containers, antimicrobial preservatives are added to inhibit the growth of microorganisms that may be introduced from repeatedly withdrawing individual doses.

Antimicrobial preservatives should not be used as a substitute for good manufacturing practices or solely to reduce the viable microbial population of a nonsterile product or control the presterilization bioburden of multidose formulations during manufacturing. Antimicrobial preservatives in compendial dosage forms meet the requirements for Added Substances under Ingredients and Processes in the General Notices.

All useful antimicrobial agents are toxic substances. For maximum protection of patients, the concentration of the preservative shown to be effective in the final packaged product should be below a level that may be toxic to human beings.

The concentration of an added antimicrobial preservative can be kept at a minimum if the active ingredients of the formulation possess an intrinsic antimicrobial activity. Antimicrobial effectiveness, whether inherent in the product or whether produced because of the addition of an antimicrobial preservative, must be demonstrated for all injections packaged in multiple-dose containers or for other products containing antimicrobial preservatives. Antimicrobial effectiveness must be demonstrated for multiple-dose topical and oral dosage forms and for other dosage forms such as ophthalmic, otic, nasal, irrigation, and dialysis fluids (see [Pharmaceutical Dosage Forms](#) 1151).

This chapter provides tests to demonstrate the effectiveness of antimicrobial protection. Added antimicrobial preservatives must be declared on the label. The tests and criteria for effectiveness apply to a product in the original, unopened container in which it was distributed by the manufacturer.

#### PRODUCT CATEGORIES

For the purpose of testing, compendial articles have been divided into four categories (see [Table 1](#)). The criteria of antimicrobial effectiveness for these products are a function of the route of administration.

Table 1. Compendial Product Categories

Category	Product Description
1	Injections, other parenterals including emulsions, otic products, sterile nasal products, and ophthalmic products made with aqueous bases or vehicles.
2	Topically used products made with aqueous bases or vehicles, nonsterile nasal products, and emulsions, including those applied to mucous membranes.
3	Oral products other than antacids, made with aqueous bases or vehicles.
4	Antacids made with an aqueous base.

#### TEST ORGANISMS

Use cultures of the following microorganisms<sup>1</sup>: *Candida albicans* (ATCC No. 10231), *Aspergillus niger* (ATCC No. 16404), *Escherichia coli* (ATCC No. 8739), *Pseudomonas aeruginosa* (ATCC No. 9027), and *Staphylococcus aureus* (ATCC No. 6538). The viable microorganisms used in the test must not be more than five passages removed from the original ATCC culture. For purposes of the test, one passage is defined as the transfer of organisms from an established culture to fresh medium. All transfers are counted. In the case of organisms maintained by seed-lot techniques, each cycle of freezing, thawing, and revival in fresh medium is taken as one transfer. A seed-stock technique should be used for long-term storage of cultures. Cultures received from the ATCC should be resuscitated according to directions. If grown in broth, the cells are pelleted by centrifugation. Resuspend in 1/20th the volume of fresh maintenance broth, and add an equal volume of 20% (v/v in water) sterile glycerol. Cells grown on agar may be scraped from the surface into the 10% glycerol broth. Dispense small aliquots of the suspension into sterile vials. Store the vials in liquid nitrogen or in a mechanical freezer at no more than  $-50^{\circ}\text{C}$ . When a fresh seed-stock

material is required, it may be removed and used to inoculate a series of working cultures. These working cultures may then be used periodically (each day in the case of bacteria and yeast) to start the inoculum culture.

#### MEDIA

All media used in the test must be tested for growth promotion. Use the microorganisms indicated above under Test Organisms.

#### PREPARATION OF INOCULUM

Preparatory to the test, inoculate the surface of a suitable volume of solid agar medium from a recently revived stock culture of each of the specified microorganisms. The culture conditions for the inoculum culture are described in [Table 2](#) in which the suitable media are Soybean-Casein Digest or Sabouraud Dextrose Agar Medium (see [Microbial Enumeration Tests](#) [61](#) and [Tests for Specified Microorganisms](#) [62](#)).

To harvest the bacterial and *C. albicans* cultures, use sterile saline TS, washing the surface growth, collecting it in a suitable vessel, and adding sufficient sterile saline TS to obtain a microbial count of about  $1 \times 10^8$  colony-forming units (cfu) per mL. To harvest the cells of *A. niger*, use sterile saline TS containing 0.05% of polysorbate 80, and add sufficient sterile saline TS to obtain a count of about  $1 \times 10^8$  cfu per mL.

Alternatively, the stock culture organisms may be grown in a suitable liquid medium (i.e., Soybean-Casein Digest Broth or Sabouraud Dextrose Broth) and the cells harvested by centrifugation, then washed and resuspended in sterile saline TS to obtain a microbial count of about  $1 \times 10^8$  cfu per mL. [note—The estimate of inoculum concentration may be performed by turbidimetric measurements for the challenge microorganisms. Refrigerate the suspension if it is not used within 2 hours.]

Determine the number of cfu per mL in each suspension, using the conditions of media and microbial recovery incubation times listed in Table 2 to confirm the initial cfu per mL estimate. This value serves to calibrate the size of inoculum used in the test. The bacterial and yeast suspensions are to be used within 24 hours of harvest, but the fungal preparation may be stored under refrigeration for up to 7 days.

#### PROCEDURE

The test can be conducted either in five original containers if sufficient volume of product is available in each container and the product container can be entered aseptically (i.e., needle and syringe through an elastomeric rubber stopper), or in five sterile, capped bacteriological containers of suitable size into which a sufficient volume of product has been transferred. Inoculate each container with one of the prepared and standardized inoculum, and mix. The volume of the suspension inoculum used is between 0.5% and 1.0% of the volume of the product. The concentration of test microorganisms that is added to the product (Categories 1, 2, and 3) are such that the final concentration of the test preparation after inoculation is between  $1 \times 10^5$  and  $1 \times 10^6$  cfu per mL of the product. For Category 4 products (antacids) the final concentration of the test preparation after inoculation is between  $1 \times 10^3$  and  $1 \times 10^4$  cfu per mL of the product.

The initial concentration of viable microorganisms in each test preparation is estimated based on the concentration of microorganisms in each of the standardized inoculum as determined by the plate-count method.

Incubate the inoculated containers at  $22.5 \pm 2.5^\circ$ . Sample each container at the appropriate intervals specified in [Table 3](#). Record any changes observed in appearance at these intervals. Determine by the plate-count procedure the number of cfu present in each test preparation for the applicable intervals (see Procedure under [Microbial Enumeration Tests](#) [61](#) and [Tests for Specified Microorganisms](#) [62](#)). Incorporate an inactivator (neutralizer) of the specific antimicrobial in the plate count or in the appropriate dilution prepared for plating. These conditions are determined in the validation study for that sample based upon the conditions of media and microbial recovery incubation times listed in [Table 2](#). Using the calculated concentrations of cfu per mL present at the start of the test, calculate the change in  $\log_{10}$  values of the concentration of cfu per mL for each microorganism at the applicable test intervals, and express the changes in terms of log reductions.

Table 2. Culture Conditions for Inoculum Preparation

Organism	Suitable Medium	Incubation Temperature	Inoculum Incubation Time	Microbial Recovery Incubation Time
Escherichia coli (ATCC No. 8739)	Soybean-Casein Digest Broth; Soybean-Casein Digest Agar	$32.5 \pm 2.5^\circ$	18 to 24 hours	3 to 5 days
Pseudomonas aeruginosa (ATCC No. 9027)	Soybean-Casein Digest Broth; Soybean-Casein Digest Agar	$32.5 \pm 2.5^\circ$	18 to 24 hours	3 to 5 days
Staphylococcus aureus (ATCC No. 6538)	Soybean-Casein Digest Broth; Soybean-Casein Digest Agar	$32.5 \pm 2.5^\circ$	18 to 24 hours	3 to 5 days
Candida albicans (ATCC No. 10231)	Sabouraud Dextrose Agar; Sabouraud Dextrose Broth	$22.5 \pm 2.5^\circ$	44 to 52 hours	3 to 5 days
Aspergillus niger (ATCC No. 16404)	Sabouraud Dextrose Agar; Sabouraud Dextrose Broth	$22.5 \pm 2.5^\circ$	6 to 10 days	3 to 7 days

#### CRITERIA FOR ANTIMICROBIAL EFFECTIVENESS

The requirements for antimicrobial effectiveness are met if the criteria specified under [Table 3](#) are met (see Significant Figures and Tolerances under General Notices). No increase is defined as not more than 0.5  $\log_{10}$  unit higher than the previous value measured.

Table 3. Criteria for Tested Microorganisms

For Category 1 Products	
Bacteria:	Not less than 1.0 log reduction from the initial calculated count at 7 days, not less than 3.0 log reduction from the initial count at 14 days, and no increase from the 14 days' count at 28 days.
Yeast and Molds:	No increase from the initial calculated count at 7, 14, and 28 days.
For Category 2 Products	
Bacteria:	Not less than 2.0 log reduction from the initial count at 14 days, and no increase from the 14 days' count at 28 days.
Yeast and Molds:	No increase from the initial calculated count at 14 and 28 days.
For Category 3 Products	
Bacteria:	Not less than 1.0 log reduction from the initial count at 14 days, and no increase from the 14 days' count at 28 days.
Yeast and Molds:	No increase from the initial calculated count at 14 and 28 days.
For Category 4 Products	
Bacteria, Yeast, Molds:	No increase from the initial calculated count at 14 and 28 days.

and Molds:

## 55 BIOLOGICAL INDICATORS—RESISTANCE PERFORMANCE TESTS

### TOTAL Viable SPORE COUNT

For paper carrier biological indicators, remove three specimens of the relevant biological indicators from their original individual containers. Disperse the paper into component fibers by placing the test specimens in a sterile 250-mL cup of a suitable blender containing 100 mL of chilled, sterilized [Purified Water](#) and blending for a time known to be adequate to achieve a homogeneous suspension. It is not unusual for blending times of 15 minutes or more to be required for optimal recovery. Transfer a 10-mL aliquot of the suspension to a sterile, screw-capped 16- × 125-mm tube. For [Biological Indicator for Steam Sterilization, Paper Carrier](#), heat the tube containing the suspension in a water bath at 95° to 100° for 15 minutes (heat shock), starting the timing when the temperature reaches 95°. For [Biological Indicator for Dry-Heat Sterilization, Paper Carrier](#), and for [Biological Indicator for Ethylene Oxide Sterilization, Paper Carrier](#), heat the tube containing the suspension in a water bath at 80° to 85° for 10 minutes, starting the timing when the temperature of the spore suspension reaches 80°. Cool rapidly in an ice-water bath at 0° to 4°. Transfer two 1-mL aliquots to suitable tubes, and make appropriate serial dilutions in sterilized [Purified Water](#); the dilutions being selected as calculated to yield preferably 30 to 300 colonies, but not less than 6, on each of a pair of plates when treated as described below. Where the biological indicator has a low spore concentration, it may be necessary to modify the dilution series and to use more plates at each dilution. Prepare a separate series of plates for each aliquot. Place 1.0 mL of each selected dilution in each of two 15- × 100-mm Petri dishes. Within 20 minutes, add to each plate 20 mL of Soybean–Casein Digest Agar Medium that has been melted and cooled to 45° to 50°. Swirl to attain a homogeneous suspension, and allow it to solidify. Incubate the plates in an inverted position at 55° to 60° for [Biological Indicator for Steam Sterilization, Paper Carrier](#), and at 30° to 35° for [Biological Indicator for Ethylene Oxide Sterilization, Paper Carrier](#) and for [Biological Indicator for Dry-Heat Sterilization, Paper Carrier](#) or at the optimal recovery temperature specified by the manufacturer. Examine the plates after 24 and 48 hours, recording for each plate the number of colonies; and use the number of colonies observed after 48 hours to calculate the results. Calculate the average number of spores per specimen from the results, using the appropriate dilution factor. The test is valid if the log number of spores per carrier at 48 hours is equal to or greater than the log number after 24 hours in each case. For [Biological Indicator for Steam Sterilization, Self-Contained](#), aseptically remove the three carriers from the container, and proceed as directed for [Biological Indicator for Steam Sterilization, Paper Carrier](#).

For [Biological Indicators for Moist Heat, Dry Heat, and Gaseous Modes of Sterilization, Nonpaper Carriers](#), aseptically remove the three carriers from their original packaging or container. Place each carrier in a suitable sterile container containing 100 mL of chilled [Purified Water](#), and sonicate or shake on a reciprocal shaker for an appropriate time. Fifteen minutes or more may be required for optimal recovery. A previous study should be conducted that ensures that the recovery method results in at least 50% to 300% recovery of the labeled spore viable count. Transfer a 10-mL aliquot of the suspension to a sterile, screw-capped 16- × 125-mm tube. Heat the tubes containing suspensions of *Bacillus atrophaeus*, *Bacillus subtilis*, and *Bacillus coagulans* at 80° to 85° for 10 minutes. Heat the tubes containing a suspension of *Geobacillus stearothermophilus* at 95° to 100° for 15 minutes. Start the timing when the lowest temperature of the stated temperature ranges is reached. Cool rapidly in an ice-water bath at 0° to 4°. Transfer two 1-mL aliquots to suitable tubes, and make appropriate serial dilutions in [Purified Water](#). The selected dilutions should be those that will preferably yield 30 to 300 colonies but not fewer than 6 on each pair of plates when treated as described below. When the biological indicator has a low spore concentration, it may be necessary to modify the dilution series and to use more plates at each dilution. Prepare a separate series of plates for each aliquot. Place 1.0 mL of each selected dilution in each of two 15- × 100-mm Petri dishes. Within 20 minutes add the aliquot to each plate containing 20 mL of agar that has been melted and cooled to between 45° and 50°. Swirl to attain a homogeneous suspension.

For *G. stearothermophilus*, *B. atrophaeus*, *B. subtilis*, and *B. coagulans*, use Soybean–Casein Digest Agar Medium and incubate the plates in an inverted position aerobically at the following respective temperatures for each microorganism: 55° to 60°, 30° to 35°, and 48° to 52°, or at the optimum temperature specified by the biological indicator manufacturer. Examine the plates after 24 and 48 hours. Record the number of colonies observed on each plate. Calculate the average number of spores per carrier from the results, using the appropriate dilution factor. The test is valid if the log number of spores per carrier at 48 hours is equal to or greater than the log number after 24 hours in each case.

For [Biological Indicators for Moist Heat, Dry Heat, and Gaseous Modes of Sterilization, Liquid Spore Suspensions](#), using *G. stearothermophilus*, *B. atrophaeus*, *B. subtilis*, and *B. coagulans* as biological indicators, prepare an appropriate serial dilution of the original spore suspension in chilled [Purified Water](#) contained in a sterile, screw-capped 16- × 125-mm tube, and proceed with the viable spore count procedures specified under [Biological Indicators for Moist Heat, Dry Heat, and Gaseous Modes of Sterilization, Nonpaper Carriers](#).

### D-VALUE DETERMINATION

Conduct all the tests described in this section under aseptic conditions, using sterilized equipment for nonthermophilic microorganisms. D-value determination for *G. stearothermophilus* and *B. coagulans* can be performed in a controlled but unclassified environment.

#### Apparatus

The test equipment for the determination of microbial resistance is described in substantial detail in ISO 18472, Sterilization of Health Care Products—Biological and Chemical Indicators—Test Equipment.<sup>1</sup> The details of individual Biological Indicator Evaluation Resistometers (BIERs) vary with the specifics of their design and the particular sterilization process in conjunction with which they are used. Provided that the performance of the BIER vessel meets the requirements of the ISO standard for exposure of the biological indicator, design differences are acceptable.

#### Procedure

Carry out the tests for D value at each of the applicable sets of sterilization conditions for which the packaged biological indicator under test is labeled for use. Take a sufficient number of groups of specimens of biological indicators in their original individual containers, each group consisting of not less than 5 specimens. The number of groups provides a range of observations from not less than one labeled D value below the labeled survival time through not less than one labeled D value above the labeled kill time. Place each group on a separate suitable specimen holder that permits each specimen to be exposed to the prescribed sterilizing condition at a specific location in the sterilizing chamber of the BIER. Check the BIER apparatus for operating parameters using specimen holders without specimens. Select a series of sterilizing times in increments from the shortest time for the specimens to be tested. The differences in sterilizing times over the series are as constant as feasible, and the difference between adjacent times is no greater than 75% of the labeled D value.

Test procedures for the use of BIER vessels for the evaluation of microbial resistance are defined in a series of ISO standards under the 11138 series.<sup>2,3,4,5</sup> The appropriate standard should be followed for the biological indicator. The test methods and carriers used with the BIER may be adapted to the specifics of the biological indicator. The method and apparatus used for paper carriers may differ from those for other carriers and will be substantially different from those used for suspensions of biological indicators.

The D-value exposure conditions for alternative material carriers are the same as the conditions used to determine the D value for paper carriers. If the manufacturer's label permits usage of the biological indicator carrier with multiple sterilization methods, then data on D value, survival time, and kill time will need to be provided by the manufacturer for each sterilization method. It is possible that biological indicators inoculated onto carriers other than paper will be used for gaseous or vapor sterilization/decontamination methods such as vapor phase hydrogen peroxide and chlorine dioxide.

Standard physical conditions for the evaluation of biological indicators for use with vapor phase hydrogen peroxide or chlorine dioxide have not been defined. In the case of chlorine dioxide, concentration of the gas, relative humidity, and temperature are critical process control conditions that can be accurately measured. The manufacturer of biological indicators marketed for use with chlorine dioxide should state the conditions under which the D-value determination was conducted so that the user can at least discern the resistance of a lot of biological indicators as compared to their own anticipated use conditions. The situation with vapor phase hydrogen peroxide is a more complex one. Various equipment manufacturers

have proposed different decontamination or sterilization conditions. Thus, there is no standard process for the conduct of vapor phase hydrogen decontamination or surface sterilization. It follows, then, that there are no industry standard biological indicator evaluation methods for vapor hydrogen peroxide, and it has been reported that there may not be a direct correlation between vapor concentration and rate or even effectiveness of biological indicator inactivation. Additionally, it is difficult to accurately assess relative humidity, which is often defined as a critical process parameter, in the presence of vapor hydrogen peroxide. For these reasons it is more reasonable to consider resistance of biological indicators to be a relative or comparative measure from the manufacturer rather than a true D value. It follows that, depending upon equipment and processes employed, it may be impossible for an end user to duplicate the biological indicator resistance tests performed by the manufacturer.

For [Biological Indicators for Moist Heat, Dry Heat, and Gaseous Modes of Sterilization, Liquid Spore Suspensions](#), conduct D-value determinations for each of the microorganisms that are provided as a liquid spore crop suspension. The test is conducted using appropriate serial dilutions predicated upon the stated spore titer of the suspension in [Purified Water](#) in a sterile tube.

Where the suspension is placed on or in a substrate such as an elastomeric closure or formulated product, its resistance may differ from that determined in [Purified Water](#). That difference may be significant to the usage of the biological indicators and appropriate measurements made prior to use in sterilization validation activities.

#### Recovery

After completion of the sterilizing procedure for [Biological Indicator for Dry-Heat Sterilization, Paper Carrier](#); [Biological Indicator for Ethylene Oxide Sterilization, Paper Carrier](#); or [Biological Indicator for Steam Sterilization, Paper Carrier](#), whichever is applicable, and within a noted time not more than 4 hours, aseptically remove and add each strip to a suitable medium (see Media under [Sterility Tests](#) 71) to submerge the biological indicator completely in a suitable tube. For each [Biological Indicator for Steam Sterilization, Self-Contained](#) specimen, the paper strip is immersed in the self-contained medium according to manufacturers' instructions, within a noted time not more than 4 hours. Incubate each tube at the optimal recovery temperature specified by the manufacturer. Observe each inoculated medium-containing tube at appropriate intervals for a total of 7 days after inoculation. (Where growth is observed at any particular observation time, further incubation of the specimen(s) concerned may be omitted.) Note the number of specimens showing no evidence of growth at any time.

For [Biological Indicators for Moist Heat, Dry Heat, and Gaseous Modes of Sterilization, Nonpaper Carriers](#), recovery of spores from the biological indicator carriers will follow recovery procedures described in the procedures under Total Viable Spore Count. D-value determination methods for paper carrier biological indicators may be used to calculate the D value for nonpaper carriers. Incubation conditions for the microorganisms that may be used for nonpaper biological indicators are described in the Total Viable Spore Count section.

For [Biological Indicators for Moist Heat, Dry Heat, and Gaseous Modes of Sterilization, Liquid Spore Suspensions](#), the method of recovery following sterilization exposure conditions are those methods described in the Total Viable Spore Count section for liquid suspensions, and when a dry heat D-value determination is made from *B. atrophaeus* suspensions, the same recovery procedures as described under [Biological Indicator for Steam Sterilization, Paper Carrier](#) are followed.

Where *C. sporogenes* is used as a biological indicator, methods for preparation, inoculation, and recovery methods and media must be adapted to accommodate the use of this anaerobic sporeformer.

#### Calculation

The determination of D values of biological indicators can be performed using the Limited Spearman-Karber, Survival Curve Method or Stumbo-Murphy-Cochran procedures 6,7,8. It is preferable to use the same method as that defined by the biological indicator manufacturer to determine D values. The use of a different method can result in differences that are more an artifact of the method than a variation in the performance of the biological indicator.

#### Survival Time and Kill Time

Take two groups, each consisting of 10 specimens of the relevant biological indicator, in their original, individual containers. Place the specimens of a group in suitable specimen holders that permit each specimen to be exposed to the sterilizing conditions at a specific location in the BIER chamber.

Expose the specimens for the required survival time, enter the chamber, and remove the holder(s) containing the 10 specimens. Repeat the above procedure immediately, or preheat if a substantial interval has elapsed, so as to subject the second holder(s) containing 10 specimens similarly to the first conditions, but for the required kill time.

The Survival time and kill time for all monographed biological indicators is described in the official monograph under the heading for each.

## 61 MICROBIOLOGICAL EXAMINATION OF NONSTERILE PRODUCTS: MICROBIAL ENUMERATION TESTS

### INTRODUCTION

The tests described hereafter will allow quantitative enumeration of mesophilic bacteria and fungi that may grow under aerobic conditions.

The tests are designed primarily to determine whether a substance or preparation complies with an established specification for microbiological quality. When used for such purposes follow the instructions given below, including the number of samples to be taken, and interpret the results as stated below.

The methods are not applicable to products containing viable microorganisms as active ingredients.

Alternative microbiological procedures, including automated methods, may be used, provided that their equivalence to the Pharmacopeial method has been demonstrated.

#### GENERAL PROCEDURES

Carry out the determination under conditions designed to avoid extrinsic microbial contamination of the product to be examined. The precautions taken to avoid contamination must be such that they do not affect any microorganisms that are to be revealed in the test.

If the product to be examined has antimicrobial activity, this is, insofar as possible, removed or neutralized. If inactivators are used for this purpose, their efficacy and their absence of toxicity for microorganisms must be demonstrated.

If surface-active substances are used for sample preparation, their absence of toxicity for microorganisms and their compatibility with any inactivators used must be demonstrated.

#### ENUMERATION METHODS

Use the Membrane Filtration method or one of the Plate-Count Methods, as directed. The Most-Probable-Number (MPN) Method is generally the least accurate method for microbial counts; however, for certain product groups with very low bioburden, it may be the most appropriate method.

The choice of a method is based on factors such as the nature of the product and the required limit of microorganisms. The method chosen must allow testing of a sufficient sample size to judge compliance with the specification. The suitability of the chosen method must be established.

#### GROWTH PROMOTION TEST AND SUITABILITY OF THE COUNTING METHOD

##### General Considerations

The ability of the test to detect microorganisms in the presence of product to be tested must be established.

Suitability must be confirmed if a change in testing performance or a change in the product that may affect the outcome of the test, is introduced.

##### Preparation of Test Strains

Use standardized stable suspensions of test strains or prepare as stated below. Seed-lot culture maintenance techniques (seed-lot systems) are used so that the viable microorganisms used for inoculation are not more than 5 passages removed from the original master seed-lot. Grow each of the bacterial and fungal test strains separately as described in [Table 1](#).

Table 1. Preparation and Use of Test Microorganisms

Microorganism	Preparation of Test Strain	Growth Promotion		Suitability of Counting Method in the Presence of Product	
		Total Aerobic Microbial Count	Total Yeasts and Molds Count	Total Aerobic Microbial Count	Total Yeasts and Molds Count
Staphylococcus aureus such as ATCC 6538, NCIMB 9518, CIP 4.83, or NBRC 13276	Soybean-Casein Digest Agar or Soybean-Casein Digest Broth 30°–35° 18–24 hours	Soybean-Casein Digest Agar and Soybean-Casein Digest Broth ≤ 100 cfu 30°–35° ≤ 3 days		Soybean-Casein Digest Agar/MPN Soybean-Casein Digest Broth ≤ 100 cfu 30°–35° ≤ 3 days	
Pseudomonas aeruginosa such as ATCC 9027, NCIMB 8626, CIP 82.118, or NBRC 13275	Soybean-Casein Digest Agar or Soybean-Casein Digest Broth 30°–35° 18–24 hours	Soybean-Casein Digest Agar and Soybean-Casein Digest Broth ≤ 100 cfu 30°–35° ≤ 3 days		Soybean-Casein Digest Agar/MPN Soybean-Casein Digest Broth ≤ 100 cfu 30°–35° ≤ 3 days	
Bacillus subtilis such as ATCC 6633, NCIMB 8054, CIP 52.62, or NBRC 3134	Soybean-Casein Digest Agar or Soybean-Casein Digest Broth 30°–35° 18–24 hours	Soybean-Casein Digest Agar and Soybean-Casein Digest Broth ≤ 100 cfu 30°–35° ≤ 3 days		Soybean-Casein Digest Agar/MPN Soybean-Casein Digest Broth ≤ 100 cfu 30°–35° ≤ 3 days	
Candida albicans such as ATCC 10231, NCPF 3179, IP 48.72, or NBRC 1594	Sabouraud Dextrose Agar or Sabouraud Dextrose Broth 20°–25° 2–3 days	Soybean-Casein Digest Agar ≤ 100 cfu 30°–35° ≤ 5 days	Sabouraud Dextrose Agar ≤ 100 cfu 20°–25° ≤ 5 days	Soybean-Casein Digest Agar ≤ 100 cfu 30°–35° ≤ 5 days MPN: not applicable	Sabouraud Dextrose Agar ≤ 100 cfu 20°–25° ≤ 5 days
Aspergillus niger such as ATCC 16404, IMI 149007, IP 1431.83, or NBRC 9455	Sabouraud Dextrose Agar or Potato-Dextrose Agar 20°–25° 5–7 days, or until good sporulation is achieved	Soybean-Casein Digest Agar ≤ 100 cfu 30°–35° ≤ 5 days	Sabouraud Dextrose Agar ≤ 100 cfu 20°–25° ≤ 5 days	Soybean-Casein Digest Agar ≤ 100 cfu 30°–35° ≤ 5 days MPN: not applicable	Sabouraud Dextrose Agar ≤ 100 cfu 20°–25° ≤ 5 days

Use Buffered Sodium Chloride-Peptone Solution pH 7.0 or Phosphate Buffer Solution pH 7.2 to make test suspensions; to suspend *A. niger* spores, 0.05% of polysorbate 80 may be added to the buffer. Use the suspensions within 2 hours, or within 24 hours if stored between 2° and 8°. As an alternative to preparing and then diluting a fresh suspension of vegetative cells of *A. niger* or *B. subtilis*, a stable spore suspension is prepared and then an appropriate volume of the spore suspension is used for test inoculation. The stable spore suspension may be maintained at 2° to 8° for a validated period of time.

#### Negative Control

To verify testing conditions, a negative control is performed using the chosen diluent in place of the test preparation. There must be no growth of microorganisms.

#### Growth Promotion of the Media

Test each batch of ready-prepared medium and each batch of medium prepared either from dehydrated medium or from the ingredients described.

Inoculate portions/plates of Soybean-Casein Digest Broth and Soybean-Casein Digest Agar with a small number (not more than 100 cfu) of the microorganisms indicated in [Table 1](#), using a separate portion/plate of medium for each. Inoculate plates of Sabouraud Dextrose Agar with a small number (not more than 100 cfu) of the microorganisms indicated in [Table 1](#), using a separate plate of medium for each. Incubate according to the conditions described in [Table 1](#).

For solid media, growth obtained must not differ by a factor greater than 2 from the calculated value for a standardized inoculum. For a freshly prepared inoculum, growth of the microorganisms comparable to that previously obtained with a previously tested and approved batch of medium occurs. Liquid media are suitable if clearly visible growth of the microorganisms comparable to that previously obtained with a previously tested and approved batch of medium occurs.

#### Suitability of the Counting Method in the Presence of Product Preparation of the Sample

The method for sample preparation depends on the physical characteristics of the product to be tested. If none of the procedures described below can be demonstrated to be satisfactory, a suitable alternative procedure must be developed.

**Water-Soluble Products**— Dissolve or dilute (usually a 1 in 10 dilution is prepared) the product to be examined in Buffered Sodium Chloride-Peptone Solution pH 7.0, Phosphate Buffer Solution pH 7.2, or Soybean-Casein Digest Broth. If necessary, adjust to a pH of 6 to 8. Further dilutions, where necessary, are prepared with the same diluent.

**Nonfatty Products Insoluble in Water**— Suspend the product to be examined (usually a 1 in 10 dilution is prepared) in Buffered Sodium Chloride-Peptone Solution pH 7.0, Phosphate Buffer Solution pH 7.2, or Soybean-Casein Digest Broth. A surface-active agent such as 1 g per L of polysorbate 80 may be added to assist the suspension of poorly wettable substances. If necessary, adjust to a pH of 6 to 8. Further dilutions, where necessary, are prepared with the same diluent.

**Fatty Products**— Dissolve in isopropyl myristate sterilized by filtration, or mix the product to be examined with the minimum necessary quantity of sterile polysorbate 80 or another noninhibitory sterile surface-active reagent heated, if necessary, to not more than 40° or, in exceptional cases, to not more than 45°. Mix carefully and if necessary maintain the temperature in a water bath. Add a sufficient quantity of the prewarmed chosen diluent to make a 1 in 10 dilution of the original product. Mix carefully, while maintaining the temperature for the shortest time necessary for the formation of an emulsion. Further serial 10-fold dilutions may be prepared using the chosen diluent containing a suitable concentration of sterile polysorbate 80 or another noninhibitory sterile surface-active reagent.

**Fluids or Solids in Aerosol Form**— Aseptically transfer the product into a membrane filter apparatus or a sterile container for further sampling. Use either the total contents or a defined number of metered doses from each of the containers tested.

**Transdermal Patches**— Remove the protective cover sheets ("release liners") of the transdermal patches and place them, adhesive side upwards, on sterile glass or plastic trays. Cover the adhesive surface with a suitable sterile porous material (e.g., sterile gauze) to prevent the patches from sticking together, and transfer the patches to a suitable volume of the chosen diluent containing inactivators such as polysorbate 80 and/or lecithin. Shake the preparation vigorously for at least 30 minutes.

#### inoculation and dilution

Add to the sample prepared as directed above and to a control (with no test material included) a sufficient volume of the microbial suspension to obtain an inoculum of not more than 100 cfu. The volume of the suspension of the inoculum should not exceed 1% of the volume of diluted product.

To demonstrate acceptable microbial recovery from the product, the lowest possible dilution factor of the prepared sample must be used for the test. Where this is not possible due to antimicrobial activity or poor solubility, further appropriate protocols must be developed. If inhibition of growth by the sample cannot otherwise be avoided, the aliquot of the microbial suspension may be added after neutralization, dilution, or filtration.

#### neutralization/removal of antimicrobial activity

The number of microorganisms recovered from the prepared sample diluted as described in Inoculation and Dilution and incubated following the procedure described in Recovery of Microorganisms in the Presence of Product, is compared to the number of microorganisms recovered from the control preparation.

If growth is inhibited (reduction by a factor greater than 2), then modify the procedure for the particular enumeration test to ensure the validity of the results. Modification of the procedure may include, for example,

1. An increase in the volume of the diluent or culture medium;
2. Incorporation of a specific or general neutralizing agents into the diluent;
3. Membrane filtration; or
4. A combination of the above measures.

**Neutralizing Agents**— Neutralizing agents may be used to neutralize the activity of antimicrobial agents (see [Table 2](#)). They may be added to the chosen diluent or the medium preferably before sterilization. If used, their efficacy and their absence of toxicity for microorganisms must be demonstrated by carrying out a blank with neutralizer and without product.

Table 2. Common Neutralizing Agents/Methods for Interfering Substances

Interfering Substance	Potential Neutralizing Agents/Method
Glutaraldehyde, mercurials	Sodium hydrogen sulfite (Sodium bisulfite)
Phenolics, alcohol, aldehydes, sorbate	Dilution
Aldehydes	Glycine
Quaternary ammonium compounds (QACs), parahydroxybenzoates (parabens), bis-biguaniides	Lecithin
QACs, iodine, parabens	Polysorbate
Mercurials	Thioglycollate
Mercurials, halogens, aldehydes	Thiosulfate
EDTA (edetate)	Mg or Ca ions

If no suitable neutralizing method can be found, it can be assumed that the failure to isolate the inoculated organism is attributable to the microbicidal activity of the product. This information serves to indicate that the article is not likely to be contaminated with the given species of the microorganism. However, it is possible that the product inhibits only some of the microorganisms specified herein, but does not inhibit others not included among the test strains or those for which the latter are not representative. Then, perform the test with the highest dilution factor compatible with microbial growth and the specific acceptance criterion.

#### recovery of microorganisms in the presence of product

For each of the microorganisms listed, separate tests are performed. Only microorganisms of the added test strain are counted.

**Membrane Filtration**— Use membrane filters having a nominal pore size not greater than 0.45 µm. The type of filter material is chosen in such a way that the bacteria-retaining efficiency is not affected by the components of the sample to be investigated. For each of the microorganisms listed, one membrane filter is used.

Transfer a suitable quantity of the sample prepared as described under Preparation of the Sample, Inoculation and Dilution, and Neutralization/Removal of Antimicrobial Activity (preferably representing 1 g of the product, or less if large numbers of cfu are expected) to the membrane filter, filter immediately, and rinse the membrane filter with an appropriate volume of diluent.

For the determination of total aerobic microbial count (TAMC), transfer the membrane filter to the surface of the Soybean-Casein Digest Agar. For the determination of total combined yeasts and molds count (TYMC), transfer the membrane to the surface of the Sabouraud Dextrose Agar. Incubate the plates as indicated in [Table 1](#). Perform the counting.

Plate-Count Methods— Perform plate-count methods at least in duplicate for each medium, and use the mean count of the result.

Pour-Plate Method— For Petri dishes 9 cm in diameter, add to the dish 1 mL of the sample prepared as described under Preparation of the Sample, Inoculation and Dilution, and Neutralization/Removal of Antimicrobial Activity and 15 to 20 mL of Soybean-Casein Digest Agar or Sabouraud Dextrose Agar, both media maintained at not more than 45°. If larger Petri dishes are used, the amount of agar medium is increased accordingly. For each of the microorganisms listed in [Table 1](#), at least two Petri dishes are used.

Incubate the plates as indicated in [Table 1](#). Take the arithmetic mean of the counts per medium, and calculate the number of cfu in the original inoculum.

Surface-Spread Method— For Petri dishes 9 cm in diameter, add 15 to 20 mL of Soybean-Casein Digest Agar or Sabouraud Dextrose Agar at about 45° to each Petri dish, and allow to solidify. If larger Petri dishes are used, the volume of the agar is increased accordingly. Dry the plates, for example, in a laminar-airflow cabinet or in an incubator. For each of the microorganisms listed in [Table 1](#), at least two Petri dishes are used. Spread a measured volume of not less than 0.1 mL of the sample, prepared as directed under Preparation of the Sample, Inoculation and Dilution, and Neutralization/Removal of Antimicrobial Activity over the surface of the medium. Incubate and count as directed for Pour-Plate Method.

Most-Probable-Number (MPN) Method— The precision and accuracy of the MPN Method is less than that of the Membrane Filtration method or the Plate-Count Method. Unreliable results are obtained particularly for the enumeration of molds. For these reasons, the MPN Method is reserved for the enumeration of TAMC in situations where no other method is available. If the use of the method is justified, proceed as follows.

Prepare a series of at least three serial 10-fold dilutions of the product as described for Preparation of the Sample, Inoculation and Dilution, and Neutralization/Removal of Antimicrobial Activity. From each level of dilution, three aliquots of 1 g or 1 mL are used to inoculate three tubes with 9 to 10 mL of Soybean-Casein Digest Broth. If necessary a surface-active agent such as polysorbate 80, or an inactivator of antimicrobial agents may be added to the medium. Thus, if three levels of dilution are prepared, nine tubes are inoculated.

Incubate all tubes at 30° to 35° for not more than 3 days. If reading of the results is difficult or uncertain owing to the nature of the product to be examined, subculture in the same broth or in Soybean-Casein Digest Agar for 1 to 2 days at the same temperature, and use these results. From [Table 3](#), determine the most probable number of microorganisms per g or mL of the product to be examined.

Table 3. Most-Probable-Number Values of Microorganisms

Observed Combinations of Numbers of Tubes Showing Growth in Each Set			MPN per g or per mL of Product	95% Confidence Limits
Number of g or mL of Product per Tube	0.1	0.01		
0	0	0	<3	0-9.4
0	0	1	3	0.1-9.5
0	1	0	3	0.1-10
0	1	1	6.1	1.2-17
0	2	0	6.2	1.2-17
0	3	0	9.4	3.5-35
1	0	0	3.6	0.2-17
1	0	1	7.2	1.2-17
1	0	2	11	4-35
1	1	0	7.4	1.3-20
1	1	1	11	4-35
1	2	0	11	4-35
1	2	1	15	5-38
1	3	0	16	5-38
2	0	0	9.2	1.5-35
2	0	1	14	4-35
2	0	2	20	5-38
2	1	0	15	4-38
2	1	1	20	5-38
2	1	2	27	9-94
2	2	0	21	5-40
2	2	1	28	9-94
2	2	2	35	9-94
2	3	0	29	9-94
2	3	1	36	9-94
3	0	0	23	5-94
3	0	1	38	9-104

3	1	2	120	30-360
3	1	3	160	30-380
3	2	0	93	18-360
3	2	1	150	30-380
3	2	2	210	30-400

3	2	3	290	90-990
3	3	0	240	40-990
3	3	1	460	90-1980
3	3	2	1100	200-4000
3	3	3	>1100	

#### results and interpretation

When verifying the suitability of the Membrane Filtration method or the Plate-Count Method, a mean count of any of the test organisms not differing by a factor greater than 2 from the value of the control defined in Inoculation and Dilution in the absence of product must be obtained. When verifying the suitability of the MPN Method, the calculated value from the inoculum must be within 95% confidence limits of the results obtained with the control.

If the above criteria cannot be met for one of more of the organisms tested with any of the described methods, the method and test conditions that come closest to the criteria are used to test the product.

#### TESTING OF PRODUCTS

##### Amount Used for the Test

Unless otherwise directed, use 10 g or 10 mL of the product to be examined taken with the precautions referred to above. For fluids or solids in aerosol form, sample 10 containers. For transdermal patches, sample 10 patches.

The amount to be tested may be reduced for active substances that will be formulated in the following conditions: the amount per dosage unit (e.g., tablet, capsule, injection) is less than or equal to 1 mg, or the amount per g or mL (for preparations not presented in dose units) is less than 1 mg. In these cases, the amount of sample to be tested is not less than the amount present in 10 dosage units or 10 g or 10 mL of the product.

For materials used as active substances where the sample quantity is limited or batch size is extremely small (i.e., less than 1000 mL or 1000 g), the amount tested shall be 1% of the batch unless a lesser amount is prescribed or justified and authorized.

For products where the total number of entities in a batch is less than 200 (e.g., samples used in clinical trials), the sample size may be reduced to two units, or one unit if the size is less than 100.

Select the sample(s) at random from the bulk material or from the available containers of the preparation. To obtain the required quantity, mix the contents of a sufficient number of containers to provide the sample.

##### Examination of the Product

###### membrane filtration

Use a filtration apparatus designed to allow the transfer of the filter to the medium. Prepare the sample using a method that has been shown to be suitable as described in Growth Promotion Test and Suitability of the Counting Method, transfer the appropriate amount to each of two membrane filters, and filter immediately. Wash each filter following the procedure shown to be suitable.

For the determination of TAMC, transfer one of the membrane filters to the surface of Soybean-Casein Digest Agar. For the determination of TYMC, transfer the other membrane to the surface of Sabouraud Dextrose Agar. Incubate the plate of Soybean-Casein Digest Agar at 30° to 35° for 3 to 5 days and the plate of Sabouraud Dextrose Agar at 20° to 25° for 7 days. Calculate the number of cfu per g or per mL of product.

When examining transdermal patches, separately filter 10% of the volume of the preparation described for Preparation of the Sample through each of two sterile filter membranes. Transfer one membrane to Soybean-Casein Digest Agar for TAMC and the other membrane to Sabouraud Dextrose Agar for TYMC.

###### plate-count methods

Pour-Plate Method— Prepare the sample using a method that has been shown to be suitable as described in Growth Promotion Test and Suitability of the Counting Method. Prepare for each medium at least two Petri dishes for each level of dilution. Incubate the plates of Soybean-Casein Digest Agar at 30° to 35° for 3 to 5 days and the plates of Sabouraud Dextrose Agar at 20° to 25° for 5 to 7 days. Select the plates corresponding to a given dilution and showing the highest number of colonies less than 250 for TAMC and 50 for TYMC. Take the arithmetic mean per culture medium of the counts, and calculate the number of cfu per g or per mL of product.

Surface-Spread Method— Prepare the sample using a method that has been shown to be suitable as described in Growth Promotion Test and Suitability of the Counting Method. Prepare at least two Petri dishes for each medium and each level of dilution. For incubation and calculation of the number of cfu, proceed as directed for the Pour-Plate Method.

###### most-probable-number method

Prepare and dilute the sample using a method that has been shown to be suitable as described in Growth Promotion Test and Suitability of the Counting Method. Incubate all tubes for 3 to 5 days at 30° to 35°. Subculture if necessary, using the procedure shown to be suitable. Record for each level of dilution the number of tubes showing microbial growth. Determine the most probable number of microorganisms per g or mL of the product to be examined from [Table 3](#).

#### Interpretation of the Results

The total aerobic microbial count (TAMC) is considered to be equal to the number of cfu found using Soybean-Casein Digest Agar; if colonies of fungi are detected on this medium, they are counted as part of TAMC. The total combined yeasts and molds count (TYMC) is considered to be equal to the number of cfu found using Sabouraud Dextrose Agar; if colonies of bacteria are detected on this medium, they are counted as part of TYMC. When the TYMC is expected to exceed the acceptance criterion due to the bacterial growth, Sabouraud Dextrose Agar containing antibiotics may be used. If the count is carried out by the MPN Method, the calculated value is TAMC.

When an acceptance criterion for microbiological quality is prescribed, it is interpreted as follows:

- 101 cfu: maximum acceptable count = 20;
- 102 cfu: maximum acceptable count = 200;
- 103 cfu: maximum acceptable count = 2000;

and so forth.

The recommended solutions and media are described in [Tests for Specified Microorganisms](#) (62)

(Official May 1, 2009)

Auxiliary Information— Please [check for your question in the FAQs](#) before contacting USP.

General Chapter	<a href="#">Radhakrishna S Tirumalai, Ph.D.</a> Senior Scientist 1-301-816-8339	(MSA05) Microbiology and Sterility Assurance

## INTRODUCTION

The tests described hereafter will allow determination of the absence of, or limited occurrence of, specified microorganisms that may be detected under the conditions described.

The tests are designed primarily to determine whether a substance or preparation complies with an established specification for microbiological quality. When used for such purposes, follow the instructions given below, including the number of samples to be taken, and interpret the results as stated below.

Alternative microbiological procedures, including automated methods, may be used, provided that their equivalence to the Pharmacopeial method has been demonstrated.

## GENERAL PROCEDURES

The preparation of samples is carried out as described in [Microbiological Examination of Nonsterile Products: Microbial Enumeration Tests](#) 61.

If the product to be examined has antimicrobial activity, this is insofar as possible removed or neutralized as described in [Microbiological Examination of Nonsterile Products: Microbial Enumeration Tests](#) 61.

If surface-active substances are used for sample preparation, their absence of toxicity for microorganisms and their compatibility with any inactivators used must be demonstrated as described in [Microbiological Examination of Nonsterile Products: Microbial Enumeration Tests](#) 61.

## GROWTH-PROMOTING AND INHIBITORY PROPERTIES OF THE MEDIA AND SUITABILITY OF THE TEST

The ability of the test to detect microorganisms in the presence of the product to be tested must be established. Suitability must be confirmed if a change in testing performance or a change in the product that may affect the outcome of the test is introduced.

## Preparation of Test Strains

Use standardized stable suspensions of test strains as stated below. Seed-lot culture maintenance techniques (seed-lot systems) are used so that the viable microorganisms used for inoculation are not more than five passages removed from the original master seed-lot.

## aerobic microorganisms

Grow each of the bacterial test strains separately in containers containing Soybean-Casein Digest Broth or on Soybean-Casein Digest Agar at 30° to 35° for 18 to 24 hours. Grow the test strain for *Candida albicans* separately on Sabouraud Dextrose Agar or in Sabouraud Dextrose Broth at 20° to 25° for 2 to 3 days.

<i>Staphylococcus aureus</i>	such as ATCC 6538, NCIMB 9518, CIP 4.83, or NBRC 13276
<i>Pseudomonas aeruginosa</i>	such as ATCC 9027, NCIMB 8626, CIP 82.118, or NBRC 13275
<i>Escherichia coli</i>	such as ATCC 8739, NCIMB 8545, CIP 53.126, or NBRC 3972
<i>Salmonella enterica</i> ssp. <i>enterica</i> serotype <i>typhimurium</i> or, as an alternative,	such as ATCC 14028
<i>Salmonella enterica</i> ssp. <i>enterica</i> serotype <i>abony</i>	such as NBRC 100797, NCTC 6017, or CIP 80.39
<i>Candida albicans</i>	such as ATCC 10231, NCPF 3179, IP 48.72, or NBRC 1594

Use Buffered Sodium Chloride-Peptone Solution pH 7.0 or Phosphate Buffer Solution pH 7.2 to make test suspensions. Use the suspensions within 2 hours or within 24 hours if stored at 2° to 8°.

## clostridia

Use Clostridium sporogenes such as ATCC 11437 (NBRC 14293, NCIMB 12343, CIP 100651) or ATCC 19404 (NCTC 532 or CIP 79.3). Grow the clostridial test strain under anaerobic conditions in Reinforced Medium for Clostridia at 30° to 35° for 24 to 48 hours. As an alternative to preparing and then diluting down a fresh suspension of vegetative cells of *C. sporogenes*, a stable spore suspension is used for test inoculation. The stable spore suspension may be maintained at 2° to 8° for a validated period.

## Negative Control

To verify testing conditions, a negative control is performed using the chosen diluent in place of the test preparation. There must be no growth of microorganisms.

## Growth Promotion and Inhibitory Properties of the Media

Test each batch of ready-prepared medium and each batch of medium prepared either from dehydrated medium or from ingredients. Verify suitable properties of relevant media as described in [Table 1](#).

Table 1. Growth Promoting, Inhibitory, and Indicative Properties of Media

Test/Medium	Property	Test Strains
<b>Test for bile-tolerant Gram-negative bacteria</b>		
Enterobacteria Enrichment Broth Mossel	Growth promoting	<i>E. coli</i>
		<i>P. aeruginosa</i>
	Inhibitory	<i>S. aureus</i>
Violet Red Bile Glucose Agar	Growth promoting + Indicative	<i>E. coli</i>
		<i>P. aeruginosa</i>
<b>Test for <i>Escherichia coli</i></b>		
MacConkey Broth	Growth promoting	<i>E. coli</i>
	Inhibitory	<i>S. aureus</i>
MacConkey Agar	Growth promoting + Indicative	<i>E. coli</i>
<b>Test for <i>Salmonella</i></b>		
Rappaport Vassiliadis <i>Salmonella</i> Enrichment Broth	Growth promoting	<i>Salmonella enterica</i> ssp. <i>enterica</i> serotype <i>typhimurium</i> or
		<i>Salmonella enterica</i> ssp. <i>enterica</i> serotype <i>abony</i>
	Inhibitory	<i>S. aureus</i>
Xylose Lysine Deoxycholate Agar	Growth promoting + Indicative	<i>Salmonella enterica</i> ssp. <i>enterica</i> serotype <i>typhimurium</i> or
		<i>Salmonella enterica</i> ssp. <i>enterica</i> serotype <i>abony</i>

	Indicative	E. coli
<b>Test for Pseudomonas aeruginosa</b>		
Cetrimide Agar	Growth promoting	P. aeruginosa
	Inhibitory	E. coli
<b>Test for Staphylococcus aureus</b>		
Mannitol Salt Agar	Growth promoting + Indicative	S. aureus
	Inhibitory	E. coli
<b>Test for Clostridia</b>		
Reinforced Medium for Clostridia	Growth promoting	Cl. sporogenes
Columbia Agar	Growth promoting	Cl. sporogenes
<b>Test for Candida albicans</b>		
Sabouraud Dextrose Broth	Growth promoting	C. albicans
Sabouraud Dextrose Agar	Growth promoting + Indicative	C. albicans

Test for Growth-Promoting Properties, Liquid Media— Inoculate a portion of the appropriate medium with a small number (not more than 100 cfu) of the appropriate microorganism. Incubate at the specified temperature for not more than the shortest period of time specified in the test. Clearly visible growth of the microorganism comparable to that previously obtained with a previously tested and approved batch of medium occurs.

Test for Growth-Promoting Properties, Solid Media— Perform Surface-Spread Method (see Plate-Count Methods under [Microbiological Examination of Nonsterile Products: Microbial Enumeration Tests \(61\)](#)), inoculating each plate with a small number (not more than 100 cfu) of the appropriate microorganism. Incubate at the specified temperature for not more than the shortest period of time specified in the test. Growth of the microorganism comparable to that previously obtained with a previously tested and approved batch of medium occurs.

Test for Inhibitory Properties, Liquid or Solid Media— Inoculate the appropriate medium with at least 100 cfu of the appropriate microorganism. Incubate at the specified temperature for not less than the longest period of time specified in the test. No growth of the test microorganism occurs.

Test for Indicative Properties— Perform Surface-Spread Method (see Plate-Count Methods under [Microbiological Examination of Nonsterile Products: Microbial Enumeration Tests \(61\)](#)), inoculating each plate with a small number (not more than 100 cfu) of the appropriate microorganism. Incubate at the specified temperature for a period of time within the range specified in the test. Colonies are comparable in appearance and indication reactions to those previously obtained with a previously tested and approved batch of medium.

#### Suitability of the Test Method

For each new product to be tested perform sample preparation as described in the relevant paragraph under Testing of Products. At the time of mixing, add each test strain in the prescribed growth medium. Inoculate the test strains individually. Use a number of microorganisms equivalent to not more than 100 cfu in the inoculated test preparation.

Perform the test as described in the relevant paragraph under Testing of Products using the shortest incubation period prescribed.

The specified microorganisms must be detected with the indication reactions as described under Testing of Products.

Any antimicrobial activity of the product necessitates a modification of the test procedure (see Neutralization/Removal of Antimicrobial Activity under [Microbiological Examination of Nonsterile Products: Microbial Enumeration Tests \(61\)](#)).

For a given product, if the antimicrobial activity with respect to a microorganism for which testing is prescribed cannot be neutralized, then it is to be assumed that the inhibited microorganism will not be present in the product.

### TESTING OF PRODUCTS

#### Bile-Tolerant Gram-Negative Bacteria

Sample Preparation and Pre-Incubation— Prepare a sample using a 1 in 10 dilution of not less than 1 g of the product to be examined as described in [Microbiological Examination of Nonsterile Products: Microbial Enumeration Tests \(61\)](#), but using Soybean-Casein Digest Broth as the chosen diluent, mix, and incubate at 20° to 25° for a time sufficient to resuscitate the bacteria but not sufficient to encourage multiplication of the organisms (usually 2 hours but not more than 5 hours).

Test for Absence— Unless otherwise prescribed, use the volume corresponding to 1 g of the product, as prepared in Sample Preparation and Pre-Incubation, to inoculate Enterobacteria Enrichment Broth Mossel. Incubate at 30° to 35° for 24 to 48 hours. Subculture on plates of Violet Red Bile Glucose Agar. Incubate at 30° to 35° for 18 to 24 hours.

The product complies with the test if there is no growth of colonies.

#### Quantitative Test—

Selection and Subculture— Inoculate suitable quantities of Enterobacteria Enrichment Broth Mossel with the preparation as directed under Sample Preparation and Pre-Incubation and/or dilutions of it containing respectively 0.1 g, 0.01 g, and 0.001 g (or 0.1 mL, 0.01 mL, and 0.001 mL) of the product to be examined. Incubate at 30° to 35° for 24 to 48 hours.

Subculture each of the cultures on a plate of Violet Red Bile Glucose Agar. Incubate at 30° to 35° for 18 to 24 hours.

Interpretation— Growth of colonies constitutes a positive result. Note the smallest quantity of the product that gives a positive result and the largest quantity that gives a negative result. Determine from [Table 2](#) the probable number of bacteria.

Table 2. Interpretation of Results

Results for Each Quantity of Product			Probable Number of Bacteria per g or mL of Product
0.1 g or 0.1 mL	0.01 g or 0.01 mL	0.001 g or 0.001 mL	
+	+	+	more than 103
+	+	-	less than 103 and more than 102
+	-	-	less than 102 and more than 10
-	-	-	less than 10

#### Escherichia coli

Sample Preparation and Pre-Incubation— Prepare a sample using a 1 in 10 dilution of not less than 1 g of the product to be examined as described in [Microbiological Examination of Nonsterile Products: Microbial Enumeration Tests \(61\)](#), and use 10 mL or the quantity corresponding to 1 g or 1 mL, to inoculate a suitable amount (determined as described under Suitability of the Test Method) of Soybean-Casein Digest Broth, mix, and incubate at 30° to 35° for 18 to 24 hours.

Selection and Subculture— Shake the container, transfer 1 mL of Soybean-Casein Digest Broth to 100 mL of MacConkey Broth, and incubate at 42° to 44° for 24 to 48 hours.

Subculture on a plate of MacConkey Agar at 30° to 35° for 18 to 72 hours.

Interpretation— Growth of colonies indicates the possible presence of *E. coli*. This is confirmed by identification tests.

The product complies with the test if no colonies are present or if the identification tests are negative.

#### Salmonella

Sample Preparation and Pre-Incubation— Prepare the product to be examined as described in [Microbiological Examination of Nonsterile Products: Microbial Enumeration Tests](#) (61), and use the quantity corresponding to not less than 10 g or 10 mL to inoculate a suitable amount (determined as described under Suitability of the Test Method) of Soybean–Casein Digest Broth, mix, and incubate at 30° to 35° for 18 to 24 hours.

Selection and Subculture— Transfer 0.1 mL of Soybean–Casein Digest Broth to 10 mL of Rappaport Vassiliadis Salmonella Enrichment Broth, and incubate at 30° to 35° for 18 to 24 hours. Subculture on plates of Xylose Lysine Deoxycholate Agar. Incubate at 30° to 35° for 18 to 48 hours.

Interpretation— The possible presence of *Salmonella* is indicated by the growth of well-developed, red colonies, with or without black centers. This is confirmed by identification tests.

The product complies with the test if colonies of the types described are not present or if the confirmatory identification tests are negative.

#### Pseudomonas aeruginosa

Sample Preparation and Pre-Incubation— Prepare a sample using a 1 in 10 dilution of not less than 1 g of the product to be examined as described in [Microbiological Examination of Nonsterile Products: Microbial Enumeration Tests](#) (61), and use 10 mL or the quantity corresponding to 1 g or 1 mL to inoculate a suitable amount (determined as described under Suitability of the Test Method) of Soybean–Casein Digest Broth, and mix. When testing transdermal patches, filter the volume of sample corresponding to one patch of the preparation (see Transdermal Patches under Preparation of the Sample in [Microbiological Examination of Nonsterile Products: Microbial Enumeration Tests](#) (61)) through a sterile filter membrane, and place in 100 mL of Soybean–Casein Digest Broth. Incubate at 30° to 35° for 18 to 24 hours.

Selection and Subculture— Subculture on a plate of Cetrimide Agar, and incubate at 30° to 35° for 18 to 72 hours.

Interpretation— Growth of colonies indicates the possible presence of *P. aeruginosa*. This is confirmed by identification tests.

The product complies with the test if colonies are not present or if the confirmatory identification tests are negative.

#### Staphylococcus aureus

Sample Preparation and Pre-Incubation— Prepare a sample using a 1 in 10 dilution of not less than 1 g of the product to be examined as described in [Microbiological Examination of Nonsterile Products: Microbial Enumeration Tests](#) (61), and use 10 mL or the quantity corresponding to 1 g or 1 mL to inoculate a suitable amount (determined as described under Suitability of the Test Method) of Soybean–Casein Digest Broth, and homogenize. When testing transdermal patches, filter the volume of sample corresponding to one patch of the preparation (see Transdermal Patches under Preparation of the Sample in [Microbiological Examination of Nonsterile Products: Microbial Enumeration Tests](#) (61)) through a sterile filter membrane, and place in 100 mL of Soybean–Casein Digest Broth. Incubate at 30° to 35° for 18 to 24 hours.

Selection and Subculture— Subculture on a plate of Mannitol Salt Agar, and incubate at 30° to 35° for 18 to 72 hours.

Interpretation— The possible presence of *S. aureus* is indicated by the growth of yellow or white colonies surrounded by a yellow zone. This is confirmed by identification tests.

The product complies with the test if colonies of the types described are not present or if the confirmatory identification tests are negative.

#### Clostridia

Sample Preparation and Heat Treatment— Prepare the product to be examined as described in [Microbiological Examination of Nonsterile Products: Microbial Enumeration Tests](#) (61). Take two equal portions corresponding to not less than 1 g or 1 mL of the product to be examined. Heat one portion at 80° for 10 minutes, and cool rapidly. Do not heat the other portion.

Selection and Subculture— Transfer 10 mL of each of the mixed portions to two containers (38 mm × 200 mm) or other containers containing 100 mL of Reinforced Medium for Clostridia. Incubate under anaerobic conditions at 30° to 35° for 48 hours. After incubation, make subcultures from each tube on Columbia Agar, and incubate under anaerobic conditions at 30° to 35° for 48 hours.

Interpretation— The occurrence of anaerobic growth of rods (with or without endospores) giving a negative catalase reaction indicates the presence of Clostridia.

If no anaerobic growth of microorganisms is detected on Columbia Agar or the catalase test is positive, the product complies with the test.

#### Candida albicans

Sample Preparation and Pre-Incubation— Prepare the product to be examined as described in [Microbiological Examination of Nonsterile Products: Microbial Enumeration Tests](#) (61), and use 10 mL or the quantity corresponding to not less than 1 g or 1 mL, to inoculate 100 mL of Sabouraud Dextrose Broth, and mix. Incubate at 30° to 35° for 3 to 5 days.

Selection and Subculture— Subculture on a plate of Sabouraud Dextrose Agar, and incubate at 30° to 35° for 24 to 48 hours.

Interpretation— Growth of white colonies may indicate the presence of *C. albicans*. This is confirmed by identification tests.

The product complies with the test if such colonies are not present or if the confirmatory identification tests are negative.

#### RECOMMENDED SOLUTIONS AND CULTURE MEDIA

[note—This section is given for information.]

The following solutions and culture media have been found satisfactory for the purposes for which they are prescribed in the test for microbial contamination in the Pharmacopeia.

Other media may be used if they have similar growth-promoting and inhibitory properties.

Stock Buffer Solution— Transfer 34 g of potassium dihydrogen phosphate to a 1000-mL volumetric flask, dissolve in 500 mL of [Purified Water](#), adjust with sodium hydroxide to a pH of 7.2 ± 0.2, add [Purified Water](#) to volume, and mix. Dispense in containers, and sterilize. Store at a temperature of 2° to 8°.

Phosphate Buffer Solution pH 7.2— Prepare a mixture of [Purified Water](#) and Stock Buffer Solution (800:1 v/v), and sterilize.

Buffered Sodium Chloride–Peptone Solution pH 7.0	
Potassium Dihydrogen Phosphate	3.6 g
Disodium Hydrogen Phosphate Dihydrate	7.2 g (equivalent to 0.067 M phosphate)
Sodium Chloride	4.3 g
Peptone (meat or casein)	1.0 g
Purified Water	1000 mL

Sterilize in an autoclave using a validated cycle.

Soybean-Casein Digest Broth	
Pancreatic Digest of Casein	17.0 g
Papaic Digest of Soybean	3.0 g
Sodium Chloride	5.0 g
Dibasic Hydrogen Phosphate	2.5 g
Glucose Monohydrate	2.5 g
Purified Water	1000 mL

Adjust the pH so that after sterilization it is  $7.3 \pm 0.2$  at  $25^{\circ}\text{C}$ . Sterilize in an autoclave using a validated cycle.

Soybean-Casein Digest Agar	
Pancreatic Digest of Casein	15.0 g
Papaic Digest of Soybean	5.0 g
Sodium Chloride	5.0 g
Agar	15.0 g
Purified Water	1000 mL

Adjust the pH so that after sterilization it is  $7.3 \pm 0.2$  at  $25^{\circ}\text{C}$ . Sterilize in an autoclave using a validated cycle.

Sabouraud Dextrose Agar	
Dextrose	40.0 g
Mixture of Peptic Digest of Animal Tissue and Pancreatic Digest of Casein (1:1)	10.0 g
Agar	15.0 g
Purified Water	1000 mL

Adjust the pH so that after sterilization it is  $5.6 \pm 0.2$  at  $25^{\circ}\text{C}$ . Sterilize in an autoclave using a validated cycle.

Potato Dextrose Agar	
Infusion from potatoes	200 g
Dextrose	20.0 g
Agar	15.0 g
Purified Water	1000 mL

Adjust the pH so that after sterilization it is  $5.6 \pm 0.2$  at  $25^{\circ}\text{C}$ . Sterilize in an autoclave using a validated cycle.

Sabouraud Dextrose Broth	
Dextrose	20.0 g
Mixture of Peptic Digest of Animal Tissue and Pancreatic Digest of Casein (1:1)	10.0 g
Purified Water	1000 mL

Adjust the pH so that after sterilization it is  $5.6 \pm 0.2$  at  $25^{\circ}\text{C}$ . Sterilize in an autoclave using a validated cycle.

Enterobacteria Enrichment Broth Mossel	
Pancreatic Digest of Gelatin	10.0 g
Glucose Monohydrate	5.0 g
Dehydrated Ox Bile	20.0 g
Potassium Dihydrogen Phosphate	2.0 g
Disodium Hydrogen Phosphate Dihydrate	8.0 g
Brilliant Green	15 mg
Purified Water	1000 mL

Adjust the pH so that after heating it is  $7.2 \pm 0.2$  at  $25^{\circ}\text{C}$ . Heat at  $100^{\circ}\text{C}$  for 30 minutes, and cool immediately.

Violet Red Bile Glucose Agar	
Yeast Extract	3.0 g
Pancreatic Digest of Gelatin	7.0 g
Bile Salts	1.5 g
Sodium Chloride	5.0 g
Glucose Monohydrate	10.0 g
Agar	15.0 g
Neutral Red	30 mg
Crystal Violet	2 mg
Purified Water	1000 mL

Adjust the pH so that after heating it is  $7.4 \pm 0.2$  at  $25^{\circ}\text{C}$ . Heat to boiling; do not heat in an autoclave.

MacConkey Broth	

Pancreatic Digest of Gelatin	20.0 g
Lactose Monohydrate	10.0 g
Dehydrated Ox Bile	5.0 g
Bromocresol Purple	10 mg
Purified Water	1000 mL

Adjust the pH so that after sterilization it is  $7.3 \pm 0.2$  at  $25^{\circ}$ . Sterilize in an autoclave using a validated cycle.

MacConkey Agar	
Pancreatic Digest of Gelatin	17.0 g
Peptones (meat and casein)	3.0 g
Lactose Monohydrate	10.0 g
Sodium Chloride	5.0 g
Bile Salts	1.5 g
Agar	13.5 g
Neutral Red	30.0 mg
Crystal Violet	1 mg
Purified Water	1000 mL

Adjust the pH so that after sterilization it is  $7.1 \pm 0.2$  at  $25^{\circ}$ . Boil for 1 minute with constant shaking, then sterilize in an autoclave using a validated cycle.

Rappaport Vassiliadis Salmonella Enrichment Broth	
Soya Peptone	4.5 g
Magnesium Chloride Hexahydrate	29.0 g
Sodium Chloride	8.0 g
Dipotassium Phosphate	0.4 g
Potassium Dihydrogen Phosphate	0.6 g
Malachite Green	0.036 g
Purified Water	1000 mL

Dissolve, warming slightly. Sterilize in an autoclave using a validated cycle, at a temperature not exceeding  $115^{\circ}$ . The pH is to be  $5.2 \pm 0.2$  at  $25^{\circ}$  after heating and autoclaving.

Xylose Lysine Deoxycholate Agar	
Xylose	3.5 g
L-Lysine	5.0 g
Lactose Monohydrate	7.5 g
Sucrose	7.5 g
Sodium Chloride	5.0 g
Yeast Extract	3.0 g
Phenol Red	80 mg
Agar	13.5 g
Sodium Deoxycholate	2.5 g
Sodium Thiosulfate	6.8 g
Ferric Ammonium Citrate	0.8 g
Purified Water	1000 mL

Adjust the pH so that after heating it is  $7.4 \pm 0.2$  at  $25^{\circ}$ . Heat to boiling, cool to  $50^{\circ}$ , and pour into Petri dishes. Do not heat in an autoclave.

Cetrimide Agar	
Pancreatic Digest of Gelatin	20.0 g
Magnesium Chloride	1.4 g
Dipotassium Sulfate	10.0 g
Cetrimide	0.3 g
Agar	13.6 g
Purified Water	1000 mL
Glycerol	10.0 mL

Heat to boiling for 1 minute with shaking. Adjust the pH so that after sterilization it is  $7.2 \pm 0.2$  at  $25^{\circ}$ . Sterilize in an autoclave using a validated cycle.

Mannitol Salt Agar	
Pancreatic Digest of Casein	5.0 g
Peptic Digest of Animal Tissue	5.0 g
Beef Extract	1.0 g
d-Mannitol	10.0 g
Sodium Chloride	75.0 g
Agar	15.0 g
Phenol Red	0.025 g
Purified Water	1000 mL

Heat to boiling for 1 minute with shaking. Adjust the pH so that after sterilization it is  $7.4 \pm 0.2$  at  $25^\circ$ . Sterilize in an autoclave using a validated cycle.

Reinforced Medium for Clostridia	
Beef Extract	10.0 g
Peptone	10.0 g
Yeast Extract	3.0 g
Soluble Starch	1.0 g
Glucose Monohydrate	5.0 g
Cysteine Hydrochloride	0.5 g
Sodium Chloride	5.0 g
Sodium Acetate	3.0 g
Agar	0.5 g
Purified Water	1000 mL

Hydrate the agar, and dissolve by heating to boiling with continuous stirring. If necessary, adjust the pH so that after sterilization it is about  $6.8 \pm 0.2$  at  $25^\circ$ . Sterilize in an autoclave using a validated cycle.

Columbia Agar	
Pancreatic Digest of Casein	10.0 g
Meat Peptic Digest	5.0 g
Heart Pancreatic Digest	3.0 g
Yeast Extract	5.0 g
Maize Starch	1.0 g
Sodium Chloride	5.0 g
Agar, according to gelling power	10.0–15.0 g
Purified Water	1000 mL

Hydrate the agar, and dissolve by heating to boiling with continuous stirring. If necessary, adjust the pH so that after sterilization it is  $7.3 \pm 0.2$  at  $25^\circ$ . Sterilize in an autoclave using a validated cycle. Allow to cool to  $45^\circ$  to  $50^\circ$ ; add, where necessary, gentamicin sulfate corresponding to 20 mg of gentamicin base, and pour into Petri dishes.

(Official May 1, 2009)

## 71 STERILITY TESTS

◆ Portions of this general chapter have been harmonized with the corresponding texts of the European Pharmacopeia and/or the Japanese Pharmacopeia. Those portions that are not harmonized are marked with symbols (◆◆) to specify this fact.◆

The following procedures are applicable for determining whether a Pharmacopeial article purporting to be sterile complies with the requirements set forth in the individual monograph with respect to the test for sterility. Pharmacopeial articles are to be tested by the Membrane Filtration method under Test for Sterility of the Product to be Examined where the nature of the product permits. If the membrane filtration technique is unsuitable, use the Direct Inoculation of the Culture Medium method under Test for Sterility of the Product to be Examined. All devices, with the exception of Devices with Pathways Labeled Sterile, are tested using the Direct Inoculation of the Culture Medium method. Provisions for retesting are included under Observation and Interpretation of Results.

Because sterility testing is a very exacting procedure, where asepsis of the procedure must be ensured for a correct interpretation of results, it is important that personnel be properly trained and qualified. The test for sterility is carried out under aseptic conditions. In order to achieve such conditions, the test environment has to be adapted to the way in which the sterility test is performed. The precautions taken to avoid contamination are such that they do not affect any microorganisms that are to be revealed in the test. The working conditions in which the tests are performed are monitored regularly by appropriate sampling of the working area and by carrying out appropriate controls.

These Pharmacopeial procedures are not by themselves designed to ensure that a batch of product is sterile or has been sterilized. This is accomplished primarily by validation of the sterilization process or of the aseptic processing procedures.

When evidence of microbial contamination in the article is obtained by the appropriate Pharmacopeial method, the result so obtained is conclusive evidence of failure of the article to meet the requirements of the test for sterility, even if a different result is obtained by an alternative procedure. ◆ For additional information on sterility testing, see [Sterilization and Sterility Assurance of Compendial Articles](#) (1211).◆

## MEDIA

Prepare media for the tests as described below, or dehydrated formulations may be used provided that, when reconstituted as directed by the manufacturer or distributor, they meet the requirements of the Growth Promotion Test of Aerobes, Anaerobes, and Fungi. Media are sterilized using a validated process.

The following culture media have been found to be suitable for the test for sterility. Fluid Thioglycollate Medium is primarily intended for the culture of anaerobic bacteria. However, it will also detect aerobic bacteria. Soybean–Casein Digest Medium is suitable for the culture of both fungi and aerobic bacteria.

Fluid Thioglycollate Medium	
I-Cystine	0.5 g
Sodium Chloride	2.5 g
Dextrose (C <sub>6</sub> H <sub>12</sub> O <sub>6</sub> ·H <sub>2</sub> O)	5.5/5.0 g
Agar, granulated (moisture content not exceeding 15%)	0.75 g

Yeast Extract (water-soluble)	5.0 g
Pancreatic Digest of Casein	15.0 g
Sodium Thioglycollate	0.5 g
or Thioglycolic Acid	0.3 mL
Resazurin Sodium Solution (1 in 1000), freshly prepared	1.0 mL
Purified Water	1000 mL

Mix the L-cystine, sodium chloride, dextrose, yeast extract, and pancreatic digest of casein with the purified water, and heat until solution is effected. Dissolve the sodium thioglycollate or thioglycolic acid in the solution and, if necessary, add 1 N sodium hydroxide so that, after sterilization, the solution will have a pH of  $7.1 \pm 0.2$ . If filtration is necessary, heat the solution again without boiling, and filter while hot through moistened filter paper. Add the resazurin sodium solution, mix, and place the medium in suitable vessels that provide a ratio of surface to depth of medium such that not more than the upper half of the medium has undergone a color change indicative of oxygen uptake at the end of the incubation period. Sterilize using a validated process. If the medium is stored, store at a temperature between  $2^{\circ}$  and  $25^{\circ}$  in a sterile, airtight container. If more than the upper one-third of the medium has acquired a pink color, the medium may be restored once by heating the containers in a water-bath or in free-flowing steam until the pink color disappears and by cooling quickly, taking care to prevent the introduction of nonsterile air into the container.

Fluid Thioglycollate Medium is to be incubated at  $32.5 \pm 2.5^{\circ}$ .

◆ Alternative Thioglycollate Medium

Prepare a mixture having the same composition as that of the Fluid Thioglycollate Medium, but omitting the agar and the resazurin sodium solution, sterilize as directed above, and allow to cool prior to use. The pH after sterilization is  $7.1 \pm 0.2$ . Incubate under anaerobic conditions for the duration of the incubation period.

Alternative Fluid Thioglycollate Medium is to be incubated at  $32.5 \pm 2.5^{\circ}$ .

Soybean-Casein Digest Medium	
Pancreatic Digest of Casein	17.0 g
Papaic Digest of Soybean Meal	3.0 g
Sodium Chloride	5.0 g
Dibasic Potassium Phosphate	2.5 g
Dextrose (C <sub>6</sub> H <sub>12</sub> O <sub>6</sub> H <sub>2</sub> O)	2.5/2.3 g
Purified Water	1000 mL

Dissolve the solids in the Purified Water, heating slightly to effect a solution. Cool the solution to room temperature, and adjust the pH with 1 N sodium hydroxide so that, after sterilization, it will have a pH of  $7.3 \pm 0.2$ . Filter, if necessary to clarify, dispense into suitable containers, and sterilize using a validated procedure. Store at a temperature between  $2^{\circ}$  and  $25^{\circ}$  in a sterile well-closed container, unless it is intended for immediate use.

Soybean-Casein Digest Medium is to be incubated at  $22.5 \pm 2.5^{\circ}$ .

◆ Media for Penicillins or Cephalosporins

Where sterility test media are to be used in the Direct Inoculation of the Culture Medium method under Test for Sterility of the Product to be Examined, modify the preparation of Fluid Thioglycollate Medium and the Soybean-Casein Digest Medium as follows. To the containers of each medium, transfer aseptically a quantity of  $\beta$ -lactamase sufficient to inactivate the amount of antibiotic in the specimen under test. Determine the quantity of  $\beta$ -lactamase required to inactivate the antibiotic by using a  $\beta$ -lactamase preparation that has been assayed previously for its penicillin- or cephalosporin-inactivating power. [note—Supplemented  $\beta$ -lactamase media can also be used in the membrane filtration test.]

Alternatively (in an area completely separate from that used for sterility testing), confirm that an appropriate amount of  $\beta$ -lactamase is incorporated into the medium, following either method under Validation Test, using less than 100 colony-forming units (cfu) of *Staphylococcus aureus* (see Table 1) as the challenge. Typical microbial growth of the inoculated

culture must be observed as a confirmation that the  $\beta$ -lactamase concentration is appropriate.

Table 1. Strains of the Test Microorganisms Suitable for Use in the Growth Promotion Test and the Validation Test

Aerobic bacteria	
<i>Staphylococcus aureus</i> <sup>◆1◆</sup>	ATCC 6538, CIP 4.83, NCTC 10788, NCIMB 9518
<i>Bacillus subtilis</i>	ATCC 6633, CIP 52.62, NCIMB 8054
<i>Pseudomonas aeruginosa</i> <sup>◆2◆</sup>	ATCC 9027, NCIMB 8626, CIP 82.118
Anaerobic bacterium	
<i>Clostridium sporogenes</i> <sup>◆3◆</sup>	ATCC 19404, CIP 79.3, NCTC 532 or ATCC 11437
Fungi	
<i>Candida albicans</i>	ATCC 10231, IP 48.72, NCPF 3179
<i>Aspergillus niger</i>	ATCC 16404, IP 1431.83, IMI 149007

◆1 An alternative to *Staphylococcus aureus* is *Bacillus subtilis* (ATCC 6633).

◆2 An alternative microorganism is *Micrococcus luteus* (*Kocuria rhizophila*), ATCC 9341.

◆3 An alternative to *Clostridium sporogenes*, when a nonspore-forming microorganism is desired, is *Bacillus vulgaris* (ATCC 8482). [note—Seed-lot culture maintenance techniques (seed-lot systems) are used so that the viable microorganisms used for inoculation are not more than five passages removed from the original master seed lot.]

Suitability Tests

The media used comply with the following tests, carried out before, or in parallel, with the test on the product to be examined.

sterility

Confirm the sterility of each sterilized batch of medium by incubating a portion of the media at the specified incubation temperature for 14 days. No growth of microorganisms occurs.

growth promotion test of aerobes, anaerobes, and fungi

Test each lot of ready-prepared medium and each batch of medium prepared either from dehydrated medium or from ingredients <sup>◆1◆</sup>. Suitable strains of microorganisms are indicated in Table 1.

Inoculate portions of Fluid Thioglycollate Medium with a small number (not more than 100 cfu) of the following microorganisms, using a separate portion of medium for each of the

ollowing species of microorganism: Clostridium sporogenes, Pseudomonas aeruginosa, and Staphylococcus aureus. ♦Inoculate portions of Alternative Fluid Thioglycollate Medium with a small number (not more than 100 cfu) of Clostridium sporogenes.♦ Inoculate portions of Soybean–Casein Digest Medium with a small number (not more than 100 cfu) of the following microorganisms, using a separate portion of medium for each of the following species of microorganism: Aspergillus niger, Bacillus subtilis, and Candida albicans. Incubate for not more than 3 days in the case of bacteria and not more than 5 days in the case of fungi.

The media are suitable if a clearly visible growth of the microorganisms occurs.

♦storage

If prepared media are stored in unsealed containers, they can be used for 1 month, provided that they are tested for growth promotion within 2 weeks of the time of use and that color indicator requirements are met. If stored in tight containers, the media can be used for 1 year, provided that they are tested for growth promotion within 3 months of the time of use and that the color indicator requirements are met.♦

♦DILUTING AND RINSING FLUIDS FOR MEMBRANE FILTRATION

Fluid A

preparation

Dissolve 1 g of peptic digest of animal tissue in water to make 1 L, filter or centrifuge to clarify, if necessary, and adjust to a pH of  $7.1 \pm 0.2$ . Dispense into containers, and sterilize using a validated process.

preparation for penicillins or cephalosporins

Aseptically add to the above Preparation, if necessary, a quantity of sterile  $\beta$ -lactamase sufficient to inactivate any residual antibiotic activity on the membranes after the solution of the test specimen has been filtered (see Media for Penicillins or Cephalosporins).

Fluid D

To each L of Fluid A add 1 mL of polysorbate 80, adjust to a pH of  $7.1 \pm 0.2$ , dispense into containers, and sterilize using a validated process. Use this fluid for articles containing lecithin or oil, or for devices labeled as "sterile pathway."

Fluid K

Dissolve 5.0 g of peptic digest of animal tissue, 3.0 g of beef extract, and 10.0 g of polysorbate 80 in water to make 1 L. Adjust the pH to obtain, after sterilization, a pH of  $6.9 \pm 0.2$ .

Dispense into containers, and sterilize using a validated process.♦

VALIDATION TEST

Carry out a test as described below under Test for Sterility of the Product to be Examined using exactly the same methods, except for the following modifications.

Membrane Filtration

After transferring the content of the container or containers to be tested to the membrane, add an inoculum of a small number of viable microorganisms (not more than 100 cfu) to the final portion of sterile diluent used to rinse the filter.

Direct Inoculation

After transferring the contents of the container or containers to be tested (for catgut and other surgical sutures for veterinary use: strands) to the culture medium, add an inoculum of a small number of viable microorganisms (not more than 100 cfu) to the medium.

In both cases use the same microorganisms as those described above under Growth Promotion Test of Aerobes, Anaerobes, and Fungi. Perform a growth promotion test as a positive control. Incubate all the containers containing medium for not more than 5 days.

If clearly visible growth of microorganisms is obtained after the incubation, visually comparable to that in the control vessel without product, either the product possesses no antimicrobial activity under the conditions of the test or such activity has been satisfactorily eliminated. The test for sterility may then be carried out without further modification.

If clearly visible growth is not obtained in the presence of the product to be tested, visually comparable to that in the control vessels without product, the product possesses antimicrobial activity that has not been satisfactorily eliminated under the conditions of the test. Modify the conditions in order to eliminate the antimicrobial activity, and repeat the validation test.

This validation is performed (a) when the test for sterility has to be carried out on a new product; and (b) whenever there is a change in the experimental conditions of the test. The validation may be performed simultaneously with the Test for Sterility of the Product to be Examined.

TEST FOR STERILITY OF THE PRODUCT TO BE EXAMINED

♦Number of Articles to Be Tested

Unless otherwise specified elsewhere in this chapter or in the individual monograph, test the number of articles specified in [Table 3](#). If the contents of each article are of sufficient quantity (see [Table 2](#)), they may be divided so that equal appropriate portions are added to each of the specified media. [note—Perform sterility testing employing two or more of the specified media.] If each article does not contain sufficient quantities for each medium, use twice the number of articles indicated in [Table 3](#).♦

Table 2. Minimum Quantity to be Used for Each Medium

Quantity per Container	Minimum Quantity to be Used (unless otherwise justified and authorized)
Liquids (other than antibiotics)	
Less than 1 mL	The whole contents of each container
1–40 mL	Half the contents of each container, but not less than 1 mL
Greater than 40 mL, and not greater than 100 mL	20 mL
Greater than 100 mL	10% of the contents of the container, but not less than 20 mL
Antibiotic liquids	1 mL
Other preparations soluble in water or in isopropyl myristate	The whole contents of each container to provide not less than 200 mg
Insoluble preparations, creams, and ointments to be suspended or emulsified	Use the contents of each container to provide not less than 200 mg
Solids	
Less than 50 mg	The whole contents of each container
50 mg or more, but less than 300 mg	Half the contents of each container, but not less than 50 mg
300 mg–5 g	150 mg

greater than 5 g	500 mg
Devices	
Catgut and other surgical sutures for veterinary use	3 sections of a strand (each 30-cm long)
♦Surgical dressing/cotton/gauze (in packages)	100 mg per package
Sutures and other individually packaged single-use material	The whole device
Other medical devices	The whole device, cut into pieces or disassembled♦

Table 3. Minimum Number of Articles to be Tested in Relation to the Number of Articles in the Batch

Number of Items in the Batch	Minimum Number of Items to be Tested for Each Medium (unless otherwise justified and authorized)*
Parenteral preparations	
Not more than 100 containers	10% or 4 containers, whichever is the greater
More than 100 but not more than 500 containers	10 containers
More than 500 containers	2% or 20 containers, whichever is less
♦For large-volume parenterals	2% or 10 containers, whichever is less
Antibiotic solids	
Pharmacy bulk packages (<5 g)	20 containers
Pharmacy bulk packages ( $\geq$ 5 g)	6 containers
Bulks and blends	See Bulk solid products♦
Ophthalmic and other noninjectable preparations	
Not more than 200 containers	5% or 2 containers, whichever is the greater
More than 200 containers	10 containers
If the product is presented in the form of single-dose containers, apply the scheme shown above for preparations for parenteral use.	
Devices	
Catgut and other surgical sutures for veterinary use	2% or 5 packages, whichever is the greater, up to a maximum total of 20 packages
♦Not more than 100 articles	10% or 4 articles, whichever is greater
More than 100, but not more than 500 articles	10 articles
More than 500 articles	2% or 20 articles, whichever is less♦
Bulk solid products	
Up to 4 containers	Each container
More than 4 containers, but not more than 50 containers	20% or 4 containers, whichever is greater
More than 50 containers	2% or 10 containers, whichever is greater

\* If the contents of one container are enough to inoculate the two media, this column gives the number of containers needed for both the media together.

The test may be carried out using the technique of Membrane Filtration or by Direct Inoculation of the Culture Medium with the product to be examined. Appropriate negative controls are included. The technique of membrane filtration is used whenever the nature of the product permits; that is, for filterable aqueous preparations, for alcoholic or oily preparations, and for preparations miscible with, or soluble in, aqueous or oily solvents, provided these solvents do not have an antimicrobial effect in the conditions of the test.

#### Membrane Filtration

Use membrane filters having a nominal pore size not greater than 0.45  $\mu$ m whose effectiveness to retain microorganisms has been established. Cellulose nitrate filters, for example, are used for aqueous, oily, and weakly alcoholic solutions; and cellulose acetate filters, for example, are used for strongly alcoholic solutions. Specially adapted filters may be needed for certain products (e.g., for antibiotics).

The technique described below assumes that membranes about 50 mm in diameter will be used. If filters of a different diameter are used, the volumes of the dilutions and the washings should be adjusted accordingly. The filtration apparatus and membrane are sterilized by appropriate means. The apparatus is designed so that the solution to be examined can be introduced and filtered under aseptic conditions: it permits the aseptic removal of the membrane for transfer to the medium, or it is suitable for carrying out the incubation after adding the medium to the apparatus itself.

#### aqueous solutions

If appropriate, transfer a small quantity of a suitable, sterile diluent such as ♦Fluid A (see Diluting and Rinsing Fluids for Membrane Filtration)♦ onto the membrane in the apparatus and filter. The diluent may contain suitable neutralizing substances and/or appropriate inactivating substances, for example, in the case of antibiotics.

Transfer the contents of the container or containers to be tested to the membrane or membranes, if necessary, after diluting to the volume used in the Validation Test with the chosen sterile diluent, but using not less than the quantities of the product to be examined prescribed in Tables 2 and 3. Filter immediately. If the product has antimicrobial properties, wash the membrane not less than three times by filtering through it each time the volume of the chosen sterile diluent used in the Validation Test. Do not exceed a washing cycle of 5 times 200 mL, even if during validation it has been demonstrated that such a cycle does not fully eliminate the antimicrobial activity. Transfer the whole membrane to the culture medium or cut it aseptically into two equal parts, and transfer one half to each of two suitable media. Use the same volume of each medium as in the Validation Test. Alternatively, transfer the medium onto the membrane in the apparatus. Incubate the media for not less than 14 days.

#### soluble solids (other than antibiotics)

Use for each medium not less than the quantity prescribed in Tables 2 and 3 of the product dissolved in a suitable solvent, such as ♦Fluid A (Diluting and Rinsing Fluids for Membrane Filtration),♦ and proceed with the test as described above for Aqueous Solutions using a membrane appropriate to the chosen solvent.

#### oils and oily solutions

Use for each medium not less than the quantity of the product prescribed in Tables 2 and 3. Oils and oily solutions of sufficiently low viscosity may be filtered without dilution through a dry membrane. Viscous oils may be diluted as necessary with a suitable sterile diluent such as isopropyl myristate shown not to have antimicrobial activity in the conditions of the test.

Allow the oil to penetrate the membrane by its own weight, and then filter, applying the pressure or suction gradually. Wash the membrane at least three times by filtering through it

each time about 100 mL of a suitable sterile solution such as ♦Fluid A (see Diluting and Rinsing Fluids for Membrane Filtration)♦ containing a suitable emulsifying agent at a concentration shown to be appropriate in the validation of the test, for example polysorbate 80 at a concentration of 10 g per L ♦(Fluid K)♦. Transfer the membrane or membranes to the culture medium or media, or vice versa, as described above for Aqueous Solutions, and incubate at the same temperatures and for the same times.

#### ointments and creams

Use for each medium not less than the quantities of the product prescribed in [Tables 2](#) and [3](#). Ointments in a fatty base and emulsions of the water-in-oil type may be diluted to 1% in isopropyl myristate as described above, by heating, if necessary, to not more than 40°. In exceptional cases it may be necessary to heat to not more than 44°. Filter as rapidly as possible, and proceed as described above for Oils and Oily Solutions.

#### ♦prefilled syringes

For prefilled syringes without attached sterile needles, expel the contents of each syringe into one or two separate membrane filter funnels or into separate pooling vessels prior to transfer. If a separate sterile needle is attached, directly expel the syringe contents as indicated above, and proceed as directed for Aqueous Solutions. Test the sterility of the needle, using Direct Inoculation under Validation Test.

#### solids for injection other than antibiotics

Constitute the test articles as directed on the label, and proceed as directed for Aqueous Solutions or Oils and Oily Solutions, whichever applies. [note—If necessary, excess diluent can be added to aid in the constitution and filtration of the constituted test article.]

#### antibiotic solids for injection

Pharmacy Bulk Packages, < 5 g— From each of 20 containers, aseptically transfer about 300 mg of solids, into a sterile 500-mL conical flask, dissolve in about 200 mL of Fluid A (see Diluting and Rinsing Fluids for Membrane Filtration), and mix; or constitute, as directed in the labeling, each of 20 containers and transfer a quantity of liquid or suspension, equivalent to about 300 mg of solids, into a sterile 500-mL conical flask, dissolve in about 200 mL of Fluid A, and mix. Proceed as directed for Aqueous Solutions or Oils and Oily Solutions, whichever applies.

Pharmacy Bulk Packages, ≥ 5 g— From each of 6 containers, aseptically transfer about 1 g of solids into a sterile 500-mL conical flask, dissolve in about 200 mL of Fluid A, and mix; or constitute, as directed in the labeling, each of 6 containers and transfer a quantity of liquid, equivalent to about 1 g of solids, into a sterile 500-mL conical flask, dissolve in about 200 mL of Fluid A, and mix. Proceed as directed for Aqueous Solutions.

#### antibiotic solids, bulks, and blends

Aseptically remove a sufficient quantity of solids from the appropriate amount of containers (see [Table 2](#)), mix to obtain a composite, equivalent to about 6 g of solids, and transfer to a sterile 500-mL conical flask. Dissolve in about 200 mL of Fluid A, and mix. Proceed as directed for Aqueous Solutions.

#### sterile aerosol products

For fluid products in pressurized aerosol form, freeze the containers in an alcohol-dry ice mixture at least at -20° for about 1 hour. If feasible, allow the propellant to escape before aseptically opening the container, and transfer the contents to a sterile pooling vessel. Add 100 mL of Fluid D to the pooling vessel, and mix gently. Proceed as directed for Aqueous Solutions or Oils and Oily Solutions, whichever applies.

#### devices with pathways labeled sterile

Aseptically pass not less than 10 pathway volumes of Fluid D through each device tested. Collect the fluids in an appropriate sterile vessel, and proceed as directed for Aqueous Solutions or Oils and Oily Solutions, whichever applies.

In the case of sterile, empty syringes, draw sterile diluent into the barrel through the sterile needle, if attached, or through a sterile needle attached for the purpose of the test, and express the contents into a sterile pooling vessel. Proceed as directed above.♦

#### Direct Inoculation of the Culture Medium

Transfer the quantity of the preparation to be examined prescribed in [Tables 2](#) and [3](#) directly into the culture medium so that the volume of the product is not more than 10% of the volume of the medium, unless otherwise prescribed.

If the product to be examined has antimicrobial activity, carry out the test after neutralizing this with a suitable neutralizing substance or by dilution in a sufficient quantity of culture medium. When it is necessary to use a large volume of the product, it may be preferable to use a concentrated culture medium prepared in such a way that it takes into account the subsequent dilution. Where appropriate, the concentrated medium may be added directly to the product in its container.

#### oily liquids

Use media to which have been added a suitable emulsifying agent at a concentration shown to be appropriate in the validation of the test, for example polysorbate 80 at a concentration of 10 g per L.

#### ointments and creams

Prepare by diluting to about 1 in 10 by emulsifying with the chosen emulsifying agent in a suitable sterile diluent such as ♦Fluid A (see Diluting and Rinsing Fluids for Membrane Filtration).♦ Transfer the diluted product to a medium not containing an emulsifying agent.

Incubate the inoculated media for not less than 14 days. Observe the cultures several times during the incubation period. Shake cultures containing oily products gently each day. However, when thioglycollate medium or other similar medium is used for the detection of anaerobic microorganisms, keep shaking or mixing to a minimum in order to maintain anaerobic conditions.

#### catgut and other surgical sutures for veterinarian use

Use for each medium not less than the quantities of the product prescribed in [Tables 2](#) and [3](#). Open the sealed package using aseptic precautions, and remove three sections of the strand for each culture medium. Carry out the test on three sections, each 30-cm long, which have been cut off from the beginning, the center, and the end of the strand. Use whole strands from freshly opened cassette packs. Transfer each section of the strand to the selected medium. Use sufficient medium to cover adequately the material to be tested (20 mL to 150 mL).

#### ♦solids

Transfer a quantity of the product in the form of a dry solid (or prepare a suspension of the product by adding sterile diluent to the immediate container), corresponding to not less than the quantity indicated in [Tables 2](#) and [3](#). Transfer the material so obtained to 200 mL of Fluid Thioglycollate Medium, and mix. Similarly, transfer the same quantity to 200 mL of Soybean-Casein Digest Medium, and mix. Proceed as directed above.

#### purified cotton, gauze, surgical dressings, and related articles

From each package of cotton, rolled gauze bandage, or large surgical dressings being tested, aseptically remove two or more portions of 100- to 500-mg each from the innermost part of the sample. From individually packaged, single-use materials, aseptically remove the entire article. Immerse the portions or article in each medium, and proceed as directed above.

#### sterile devices

Articles can be immersed intact or disassembled. To ensure that device pathways are also in contact with the media, immerse the appropriate number of units per medium in a volume of medium sufficient to immerse the device completely, and proceed as directed above. For extremely large devices, immerse those portions of the device that are to come into contact

with the patient in a volume of medium sufficient to achieve complete immersion of those portions.

For catheters where the inside lumen and outside are required to be sterile, either cut them into pieces such that the medium is in contact with the entire lumen or fill the lumen with medium, and then immerse the intact unit.♦

#### OBSERVATION AND INTERPRETATION OF RESULTS

At intervals during the incubation period and at its conclusion, examine the media for macroscopic evidence of microbial growth. If the material being tested renders the medium turbid so that the presence or absence of microbial growth cannot be readily determined by visual examination, 14 days after the beginning of incubation transfer portions (each not less than 1 mL) of the medium to fresh vessels of the same medium, and then incubate the original and transfer vessels for not less than 4 days.

If no evidence of microbial growth is found, the product to be examined complies with the test for sterility. If evidence of microbial growth is found, the product to be examined does not comply with the test for sterility, unless it can be clearly demonstrated that the test was invalid for causes unrelated to the product to be examined. The test may be considered invalid only if one or more of the following conditions are fulfilled:

- a. The data of the microbiological monitoring of the sterility testing facility show a fault.
- b. A review of the testing procedure used during the test in question reveals a fault.
- c. Microbial growth is found in the negative controls.
- d. After determination of the identity of the microorganisms isolated from the test, the growth of this species (or these species) may be ascribed unequivocally to faults with respect to the material and or the technique used in conducting the sterility test procedure.

If the test is declared to be invalid, it is repeated with the same number of units as in the original test. If no evidence of microbial growth is found in the repeat test, the product examined complies with the test for sterility. If microbial growth is found in the repeat test, the product examined does not comply with the test for sterility.

#### APPLICATION OF THE TEST TO PARENTERAL PREPARATIONS, OPHTHALMIC, AND OTHER NONINJECTABLE PREPARATIONS REQUIRED TO COMPLY WITH THE TEST FOR STERILITY

When using the technique of membrane filtration, use, whenever possible, the whole contents of the container, but not less than the quantities indicated in [Tables 2](#) and [3](#), diluting where necessary to about 100 mL with a suitable sterile solution, such as ♦Fluid A (see Diluting and Rinsing Fluids for Membrane Filtration).♦

When using the technique of direct inoculation of media, use the quantities shown in [Tables 2](#) and [3](#), unless otherwise justified and authorized. The tests for bacterial and fungal sterility are carried out on the same sample of the product to be examined. When the volume or the quantity in a single container is insufficient to carry out the tests, the contents of two or more containers are used to inoculate the different media.

♦1 In appropriate cases, periodic testing of the different batches prepared from the same lot of dehydrated medium is acceptable.♦

Auxiliary Information— Please [check for your question in the FAQs](#) before contacting USP.

#### 81 ANTIBIOTICS—MICROBIAL ASSAYS

The activity (potency) of antibiotics may be demonstrated under suitable conditions by their inhibitory effect on microorganisms. A reduction in antimicrobial activity also will reveal subtle changes not demonstrable by chemical methods. Accordingly, microbial or biological assays remain generally the standard for resolving doubt with respect to possible loss of activity. This chapter summarizes these procedures for the antibiotics recognized in this Pharmacopeia for which microbiological assay remains the definitive method.

Two general methods are employed, the cylinder-plate or "plate" assay and the turbidimetric or "tube" assay. The first depends upon diffusion of the antibiotic from a vertical cylinder through a solidified agar layer in a petri dish or plate to an extent such that growth of the added microorganism is prevented entirely in a circular area or "zone" around the cylinder containing a solution of the antibiotic. The turbidimetric method depends upon the inhibition of growth of a microbial culture in a uniform solution of the antibiotic in a fluid medium that is favorable to its rapid growth in the absence of the antibiotic.

#### APPARATUS

All equipment is to be thoroughly cleaned before and after each use. Glassware for holding and transferring test organisms is sterilized by dry heat or by steam.

#### Temperature Control

Thermostatic control is required in several stages of a microbial assay, when culturing a microorganism and preparing its inoculum, and during incubation in plate and tube assays. Maintain the temperature of assay plates at  $\pm 0.5^{\circ}$  of the temperature selected. Closer control of the temperature ( $\pm 0.1^{\circ}$  of the selected temperature) is imperative during incubation in a tube assay, and may be achieved in either circulated air or water, the greater heat capacity of water lending it some advantage over circulating air.

#### Spectrophotometer

Measuring transmittance within a fairly narrow frequency band requires a suitable spectrophotometer in which the wavelength of the light source can be varied or restricted by the use of a 580-nm filter or a 530-nm filter for reading the absorbance in a tube assay. For the latter purpose, the instrument may be arranged to accept the tube in which incubation takes place (see Turbidimetric Assay Receptacles), to accept a modified cell fitted with a drain that facilitates rapid change of content, or preferably, fixed with a flow-through cell for a continuous flow-through analysis; set the instrument at zero absorbance with clear, uninoculated broth prepared as specified for the particular antibiotic, including the same amount of test solution and formaldehyde as found in each sample.

note—Either absorbance or transmittance measurement may be used for preparing inocula.

#### Cylinder-Plate Assay Receptacles

For assay plates, use glass or plastic petri dishes (approximately 20 × 100 mm) having covers of suitable material. For assay cylinders, use stainless steel or porcelain cylinders with the following dimensions, each dimension having a tolerance of  $\pm 0.1$  mm: outside diameter 8 mm; inside diameter 6 mm; and length 10 mm. Carefully clean cylinders to remove all residues. An occasional acid bath, e.g., with about 2 N nitric acid or with chromic acid (see [Cleaning Glass Apparatus](#) [1051](#)) is needed.

#### Turbidimetric Assay Receptacles

For assay tubes, use glass or plastic test tubes, e.g., 16 × 125 mm or 18 × 150 mm that are relatively uniform in length, diameter, and thickness and substantially free from surface blemishes and scratches. Tubes that are to be placed in the spectrophotometer are matched and are without scratches or blemishes. Cleanse thoroughly to remove all antibiotic residues and traces of cleaning solution, and sterilize tubes that have been used previously, before subsequent use.

#### MEDIA AND DILUENTS

## Media

The media required for the preparation of test organism inocula are made from the ingredients listed herein. Minor modifications of the individual ingredients, or reconstituted dehydrated media, may be substituted, provided the resulting media possess equal or better growth-promoting properties and give a similar standard curve response.

Dissolve the ingredients in water to make 1 L, and adjust the solutions with either 1 N sodium hydroxide or 1 N hydrochloric acid as required, so that after steam sterilization the pH is as specified.

## medium 1

Peptone	6.0 g
Pancreatic Digest of Casein	4.0 g
Yeast Extract	3.0 g
Beef Extract	1.5 g
Dextrose	1.0 g
Agar	15.0 g
Water	1000 mL

pH after sterilization:  $6.6 \pm 0.1$ .

## medium 2

Peptone	6.0 g
Yeast Extract	3.0 g
Beef Extract	1.5 g
Agar	15.0 g
Water	1000 mL

pH after sterilization:  $6.6 \pm 0.1$ .

## medium 3

Peptone	5.0 g
Yeast Extract	1.5 g
Beef Extract	1.5 g
Sodium Chloride	3.5 g
Dextrose	1.0 g
Dibasic Potassium Phosphate	3.68 g
Monobasic Potassium Phosphate	1.32 g
Water	1000 mL

pH after sterilization:  $7.0 \pm 0.05$ .

## medium 4

Same as Medium 2, except for the additional ingredient 1.0 g of Dextrose.

## medium 5

Same as Medium 2, except that the final pH after sterilization is  $7.9 \pm 0.1$ .

## medium 8

Same as Medium 2, except that the final pH after sterilization is  $5.9 \pm 0.1$ .

## medium 9

Pancreatic Digest of Casein	17.0 g
Papaic Digest of Soybean	3.0 g
Sodium Chloride	5.0 g
Dibasic Potassium Phosphate	2.5 g
Dextrose	2.5 g
Agar	20.0 g
Water	1000 mL

pH after sterilization:  $7.2 \pm 0.1$ .

## medium 10

Same as Medium 9, except to use 12.0 g of Agar instead of 20.0 g, and to add 10 mL of Polysorbate 80 after boiling the medium to dissolve the agar.

pH after sterilization:  $7.2 \pm 0.1$ .

## medium 11

Same as Medium 1, except that the final pH after sterilization is  $8.3 \pm 0.1$ .

## medium 13

Dextrose	20.0 g
Peptone	10.0 g
Water	1000 mL

pH after sterilization:  $5.6 \pm 0.1$ .

## medium 19

Peptone	9.4 g
Yeast Extract	4.7 g

Beef Extract	2.4 g
Sodium Chloride	10.0 g
Dextrose	10.0 g
Agar	23.5 g
Water	1000 mL

pH after sterilization:  $6.1 \pm 0.1$ .

#### medium 32

Same as Medium 1, except for the additional ingredient 0.3 g of Manganese Sulfate.

#### medium 34

Glycerol	10.0 g
Peptone	10.0 g
Beef Extract	10.0 g
Sodium Chloride	3.0 g
Water	1000 mL

pH after sterilization:  $7.0 \pm 0.1$ .

#### medium 35

Same as Medium 34, except for the additional ingredient 17.0 g of Agar.

#### medium 36

Pancreatic Digest of Casein	15.0 g
Papaic Digest of Soybean	5.0 g
Sodium Chloride	5.0 g
Agar	15.0 g
Water	1000 mL

pH after sterilization:  $7.3 \pm 0.1$ .

#### medium 39

Same as [Medium 3](#), except that the final pH after sterilization is  $7.9 \pm 0.1$ .

#### medium 40

Yeast Extract	20.0 g
Polypeptone	5.0 g
Dextrose	10.0 g
Monobasic Potassium Phosphate	2.0 g
Polysorbate 80	0.1 g
Agar	10.0 g
Water	1000 mL

pH after sterilization:  $6.7 \pm 0.2$ .

#### medium 41

Pancreatic Digest of Casein	9.0 g
Dextrose	20.0 g
Yeast Extract	5.0 g
Sodium Citrate	10.0 g
Monobasic Potassium Phosphate	1.0 g
Dibasic Potassium Phosphate	1.0 g
Water	1000 mL

pH after sterilization:  $6.8 \pm 0.1$ .

#### Phosphate Buffers and Other Solutions

Prepare as follows, or by other suitable means, the potassium phosphate buffers required for the antibiotic under assay. The buffers are sterilized after preparation, and the pH specified in each case is the pH after sterilization.

buffer no. 1, 1 percent, pH 6.0— Dissolve 2.0 g of dibasic potassium phosphate and 8.0 g of monobasic potassium phosphate in 1000 mL of water. Adjust with 18 N phosphoric acid or 10 N potassium hydroxide to a pH of  $6.0 \pm 0.05$ .

buffer no. 3, 0.1 m, pH 8.0— Dissolve 16.73 g of dibasic potassium phosphate and 0.523 g of monobasic potassium phosphate in 1000 mL of water. Adjust with 18 N phosphoric acid or 10 N potassium hydroxide to a pH of  $8.0 \pm 0.1$ .

buffer no. 4, 0.1 m, pH 4.5— Dissolve 13.61 g of monobasic potassium phosphate in 1000 mL of water. Adjust with 18 N phosphoric acid or 10 N potassium hydroxide to a pH of  $4.5 \pm 0.05$ .

buffer no. 6, 10 percent, pH 6.0— Dissolve 20.0 g of dibasic potassium phosphate and 80.0 g of monobasic potassium phosphate in 1000 mL of water. Adjust with 18 N phosphoric acid or 10 N potassium hydroxide to a pH of  $6.0 \pm 0.05$ .

buffer no. 10, 0.2 m, pH 10.5— Dissolve 35.0 g of dibasic potassium phosphate in 1000 mL of water, and add 2 mL of 10 N potassium hydroxide. Adjust with 18 N phosphoric acid or 10 N potassium hydroxide to a pH of  $10.5 \pm 0.1$ .

buffer no. 16, 0.1 m, pH 7.0— Dissolve 13.6 g of dibasic potassium phosphate and 4.0 g of monobasic potassium phosphate in 1000 mL of water. Adjust with 18 N phosphoric acid or 10 N potassium hydroxide to a pH of  $7.0 \pm 0.2$ .

other solutions— Use the substances specified under [Reagents, Indicators, and Solutions](#). For water, use Purified Water. For saline, use Sodium Chloride Injection. Dilute formaldehyde is Formaldehyde Solution diluted with water 1:3.

#### UNITS AND REFERENCE STANDARDS

The potency of antibiotics is designated in either "Units" or "µg" of activity. In each case the "Unit" or "µg" of antibiotic activity is established and defined by the designated federal master standard for that antibiotic. The corresponding USP Reference Standard is calibrated in terms of the master standard. USP Reference Standards for antibiotic substances are held and distributed by the U.S. Pharmacopeial Convention, Inc.

The concept of "µg" of activity originated from the situation where the antibiotic preparation selected as the reference standard was thought to consist entirely of a single chemical entity and was therefore assigned a potency of 1000 "µg" per mg. In several such instances, as a result of the development of manufacturing and purification methods for particular antibiotics, preparations became available that contained more than 1000 "µg" of activity per mg. It was then understood that such preparations had an activity equivalent to a given number of "µg" of the original reference standard. In most instances, however, the "µg" of activity is exactly equivalent numerically to the µg (weight) of the pure substance. Complications arise in some situations, e.g., where an antibiotic exists as the free base and in salt form, and the "µg" of activity has been defined in terms of one such form; where the antibiotic substance consists of a number of components having close chemical similarity but differing antibiotic activity; or where the potencies of a family of antibiotics are expressed in terms of a reference standard consisting of a single member which, however, might itself be heterogeneous. In such cases the "µg" of activity defined in terms of a "Master Standard" is tantamount to a "Unit." The "µg" of activity should therefore not be assumed necessarily to correspond to the µg (weight) of the antibiotic substance.

#### PREPARATION OF THE STANDARD

To prepare a stock solution, dissolve a quantity of the USP Reference Standard of a given antibiotic, accurately weighed, or the entire contents of a vial of USP Reference Standard, where appropriate, in the solvent specified in that table, and then dilute to the required concentration as indicated. Store in a refrigerator, and use within the period indicated. On the day of the assay, prepare from the stock solution five or more test dilutions, the successive solutions increasing stepwise in concentration, usually in the ratio of 1:1.25 for a cylinder-plate assay or smaller for a turbidimetric assay. Use the final diluent specified and a sequence such that the middle or median has the concentration designated.

#### PREPARATION OF THE SAMPLE

From the information available for the preparation to be assayed (the "Unknown"), assign to it an assumed potency per unit weight or volume, and on this assumption prepare on the day of the assay a stock solution and test dilution as specified for each antibiotic but with the same final diluent as used for the USP Reference Standard. The assay with five levels of the Standard requires only one level of the Unknown at a concentration assumed equal to the median level of the Standard.

#### ORGANISMS AND INOCULUM

##### Test Organisms

The test organism for each antibiotic is listed in [Table 2](#), together with its identification number in the American Type Culture Collection. The method of assay is given for each in [Table 1](#). Maintain a culture on slants of the medium and under the incubation conditions specified in [Table 3](#), and transfer weekly to fresh slants. For *K. pneumoniae* use a nonencapsulated culture. For *Enterococcus hirae*, stab cultures may be used.

Table 1. Preparation of Stock Solutions and Test Dilutions of Reference Standards

Antibiotic and Type of Assay [Cylinder-plate (CP) or Turbidimetric (T)]	Stock Solution			Test Dilution	
	Initial Solvent (and initial concentration where specified); Further Diluent, if different	Final Stock Concentration per mL	Use Within	Final Diluent	Median Dose (µg of activity or Units per mL)
Amikacin (T)	Water	1 mg	14 days	Water	10 µg
Amphotericin B (CP)	Dimethyl sulfoxide	1 mg	Same day	B. 10	1.0 µg
Bacitracin Zinc (CP)	0.01 N hydrochloric acid	100 U	Same day	B. 1	1.0 U
Bleomycin (CP)	B. 16	2 U	14 days	B. 16	0.04 U
Candidin (T)	Dimethyl sulfoxide	1 mg	Same day	Water	0.06 µg
Capreomycin (T)	Water	1 mg	7 days	Water	100 µg
Carbenicillin (CP)	B. 1	1 mg	14 days	B. 1	20 µg
Cephalothin (CP)	B. 1	1 mg	5 days	B. 1	1.0 µg
Cephapirin (CP)	B. 1	1 mg	3 days	B. 1	1.0 µg
Chloramphenicol (T)	Alcohol (10 mg/mL); [Water]	1 mg	30 days	Water	2.5 µg
Chlortetracycline (T)	0.01 N hydrochloric acid	1 mg	4 days	Water	0.06 µg
Clloxacillin (CP)	B. 1	1 mg	7 days	B. 1	5.0 µg
Colistimethate Sodium (CP)	Water (10 mg/mL); [B. 6]	1 mg	Same day	B. 6	1.0 µg
Colistin (CP)	Water (10 mg/mL); [B. 6]	1 mg	14 days	B. 6	1.0 µg
Cycloserine (T)	Water	1 mg	30 days	Water	50 µg
Demeclocycline (T)	0.1 N hydrochloric acid	1 mg	4 days	Water	0.1 µg
Dihydrostreptomycin (CP)	B. 3	1 mg	30 days	B. 3	1.0 µg
Dihydrostreptomycin (T)	Water	1 mg	30 days	Water	30 µg
Doxycycline (T)	0.1 N hydrochloric acid	1 mg	5 days	Water	0.1 µg
Erythromycin (CP)	Methanol (10 mg/mL); [B. 3]	1 mg	14 days	B. 3	1.0 µg
Gentamicin (CP)	B. 3	1 mg	30 days	B. 3	0.1 µg
Gramicidin (T)	Alcohol 95%	1 mg	30 days	Alcohol 95%	0.04 µg
Kanamycin (T)	Water	1 mg	30 days	Water	10 µg
Methacycline (T)	Water	1 mg	7 days	Water	0.06 µg
Nafcillin (CP)	B. 1	1 mg	2 days	B. 1	2.0 µg
Natamycin (CP)	Dimethyl sulfoxide	1 mg	Same	B. 10	5.00 µg

			day		
Neomycin (CP)	B. 3	1 mg	14 days	B. 3	1.0 µg
Neomycin (T)	B. 3	100 µg	14 days	B. 3	1.0 µg
Netilmicin (CP)	B. 3	1 mg	7 days	B. 3	0.1 µg
Novobiocin (CP)	Alcohol (10 mg/mL); [ B. 3]	1 mg	5 days	B. 6	0.5 µg
Nystatin (CP)	Dimethylformamide	1,000 U	Same day	B. 6	20 U
Oxytetracycline (T)	0.1 N hydrochloric acid	1 mg	4 days	Water	0.24 µg
Paromomycin (CP)	B. 3	1 mg	21 days	B. 3	1.0 µg
Penicillin G (CP)	B. 1	1,000 U	4 days	B. 1	1.0 U
Polymyxin B (CP)	Water; [ B. 6]	10,000 U	14 days	B. 6	10 U
Rolitetracycline (T)	Water	1 mg	1 day	Water	0.24 µg
Sisomicin (CP)	B. 3	1 mg	14 days	B. 3	0.1 µg
Streptomycin (T)	Water	1 mg	30 days	Water	30 µg
Tetracycline (T)	0.1 N hydrochloric acid	1 mg	1 day	Water	0.24 µg
Thiostrepton (T)	Dimethyl sulfoxide	1 U	Same day	Dimethyl sulfoxide	0.80 U
Ticarcillin (CP)	B. 1	1 mg	1 day	B. 1	5.0 µg
Tobramycin (T)	Water	1 mg	14 days	Water	2.5 µg
Troleandomycin (T)	Isopropyl alcohol-water (4:1)	1 mg	Same day	Water	25 µg
Tylosin (T)	Methanol (10 mg/mL); [ B. 16]	1 mg	30 days	B.3: methanol (1:1)	4 µg
Vancomycin (CP)	Water	1 mg	7 days	B. 4	10 µg

notes—"B" denotes "buffer," and the number following refers to the potassium phosphate buffers defined in this chapter.

For amphotericin B, colistimethate sodium, and nystatin, prepare the USP Reference Standard solutions and the sample test solution simultaneously.

For amphotericin B, further dilute the stock solution with dimethyl sulfoxide to give concentrations of 12.8, 16, 20, 25, and 31.2 µg per mL prior to making the test dilutions. The Test Dilution of the sample should contain the same amount of dimethyl sulfoxide as the test dilutions of the USP Reference Standard.

For bacitracin zinc, each of the Standard test dilutions should contain the same amount of hydrochloric acid as the Test Dilution of the sample.

For neomycin turbidimetric assay, dilute the 100-µg-per-mL stock solution quantitatively with Buffer No. 3 to obtain a solution having a concentration equivalent to 25.0 µg of neomycin per mL. To separate 50-mL volumetric flasks add 1.39, 1.67, 2.00, 2.40, and 2.88 mL of this solution, add 5.0 mL of 0.01 N hydrochloric acid to each flask, dilute with Buffer No. 3 to volume, and mix to obtain solutions having concentrations of 0.69, 0.83, 1.0, 1.2, and 1.44 µg of neomycin per mL. Use these solutions to prepare the standard response line.

For nystatin, further dilute the stock solution with dimethylformamide to give concentrations of 256, 320, 400, 500, and 624 Units per mL prior to making the test dilutions. Prepare the standard response line solutions simultaneously with dilutions of the sample to be tested. The Test Dilution of the sample should contain the same amount of dimethylformamide as the test dilutions of the Standard. Use red low-actinic glassware.

For Polymyxin B, prepare the stock solution by adding 2 mL of water for each 5 mg of the weighed USP Reference Standard material.

Table 2. Test Organisms for Antibiotics Assayed by the Procedure Indicated in Table 1

Antibiotic	Test Organism	ATCC <sup>a</sup> Number
Amikacin	Staphylococcus aureus	29737
Amphotericin B	Saccharomyces cerevisiae	9763
Bacitracin	Micrococcus luteus	10240
Bleomycin	Mycobacterium smegmatis	607
Candididin	Saccharomyces cerevisiae	9763
Capreomycin	Klebsiella pneumoniae	10031
Carbenicillin	Pseudomonas aeruginosa	25619
Cephalothin	Staphylococcus aureus	29737
Cephapirin	Staphylococcus aureus	29737
Chloramphenicol	Escherichia coli	10536
Chlortetracycline	Staphylococcus aureus	29737
Cloxacillin	Staphylococcus aureus	29737
Colistimethate Sodium	Bordetella bronchiseptica	4617
Colistin	Bordetella bronchiseptica	4617
Cycloserine	Staphylococcus aureus	29737
Demeclocycline	Staphylococcus aureus	29737
Dihydrostreptomycin (CP)	Bacillus subtilis	6633
Dihydrostreptomycin (T)	Klebsiella pneumoniae	10031
Doxycycline	Staphylococcus aureus	29737
Erythromycin	Micrococcus luteus	9341
Gentamicin	Staphylococcus epidermidis	12228
Gramicidin	Enterococcus hirae	10541
Kanamycin	Staphylococcus aureus	29737
Methacycline	Staphylococcus aureus	29737
Nafcillin	Staphylococcus aureus	29737

Neomycin (CP)	<i>Staphylococcus epidermidis</i>	12228
Neomycin (T)	<i>Klebsiella pneumoniae</i>	10031
Netilmicin	<i>Staphylococcus epidermidis</i>	12228
Novobiocin	<i>Staphylococcus epidermidis</i>	12228
Nystatin	<i>Saccharomyces cerevisiae</i>	2601
Oxytetracycline	<i>Staphylococcus aureus</i>	29737
Paromomycin	<i>Staphylococcus epidermidis</i>	12228
Penicillin G	<i>Staphylococcus aureus</i>	29737
Polymyxin B	<i>Bordetella bronchiseptica</i>	4617
Rolitetracycline	<i>Staphylococcus aureus</i>	29737
Sisomicin	<i>Staphylococcus epidermidis</i>	12228
Spectinomycin	<i>Escherichia coli</i>	10536
Streptomycin (T)	<i>Klebsiella pneumoniae</i>	10031
Tetracycline	<i>Staphylococcus aureus</i>	29737
Thiostrepton (T)	<i>Enterococcus hirae</i>	10541
Tobramycin	<i>Staphylococcus aureus</i>	29737
Troleandomycin	<i>Klebsiella pneumoniae</i>	10031
Tylosin	<i>Staphylococcus aureus</i>	9144
Vancomycin	<i>Bacillus subtilis</i>	6633

37.5

hr.

note—For *Pseudomonas aeruginosa* (ATCC 25619) in the assay of Carbenicillin, use 0.5 mL of a 1:25 dilution of the stock suspension per 100 mL of Medium 10.

#### Preparation of Inoculum

Preparatory to an assay, remove the growth from a recently grown slant or culture of the organism, with 3 mL of sterile saline TS and sterile glass beads. Inoculate the surface of 250 mL of the agar medium specified for that organism in [Table 3](#) and contained on the flat side of a Roux bottle except in the case of *Enterococcus hirae* and *Staphylococcus aureus* (ATCC 9144), which are grown in a liquid medium. Spread the suspension evenly over the surface of the agar with the aid of sterile glass beads, and incubate at the temperature shown for approximately the indicated length of time. At the end of this period, prepare the stock suspension by collecting the surface growth in 50 mL of sterile saline TS, except for *Bleomycin* (use 50 mL of [Medium 34](#)).

Determine by trial the quantity of stock suspension to be used as the Inoculum, starting with the volume suggested in [Table 3](#). The trial tests should be incubated for the times indicated in the section Turbidimetric Method for Procedure. Adjust the quantity of Inoculum on a daily basis, if necessary, to obtain the optimum dose-response relationship from the amount of growth of the test organism in the assay tubes and the length of the time of incubation. At the completion of the incubation periods described in the section Turbidimetric Method for Procedure, tubes containing the median dose of the Standard should have absorbances of at least 0.3 absorbance unit, except for *Amikacin*, *Chlortetracycline*, *Gramicidin*, and *Tetracycline* (0.35 absorbance unit), and *Capreomycin*, *Methacycline*, and *Tobramycin* (0.4 absorbance unit).

For the cylinder-plate assay, determine by trial the proportions of stock suspension to be incorporated in the Inoculum, starting with the volumes indicated in [Table 3](#), that result in satisfactory demarcation of the zones of inhibition of about 14 to 16 mm in diameter and giving a reproducible dose relationship. Prepare the inoculum by adding a portion of stock suspension to a sufficient amount of agar medium that has been melted and cooled to 45° to 50°, and swirling to attain a homogeneous suspension.

#### PROCEDURE

##### Assay Designs

Microbial assays gain markedly in precision by the segregation of relatively large sources of potential error and bias through suitable experimental designs. In a cylinder-plate assay, the essential comparisons are restricted to relationships between zone diameter measurements within plates, exclusive of the variation between plates in their preparation and subsequent handling. To conduct a turbidimetric assay so that the differences in observed turbidity will reflect the differences in the antibiotic concentration requires both greater uniformity in the environment created for the tubes through closer thermostatic control of the incubator and the avoidance of systematic bias by use of a random placement of replicate tubes in separate tube racks, each rack containing one complete set of treatments. The essential comparisons are then restricted to relationships between the observed turbidities within racks.

note—For some purposes, the practice is to design the assay so that a set of treatments consists of not fewer than three tubes for each sample and standard concentration, and each set is placed in a single rack.

Within these restrictions, the assay design recommended is a 1-level assay with a standard curve. For this assay with a standard curve, prepare solutions of 5, 6, or more test dilutions, provided they include one corresponding to the reference concentration (S3), of the Standard and a solution of a single median test level of the Unknown as described under Preparation of Standard and Preparation of the Sample. Consider an assay as preliminary if its computed potency with either design is less than 80% or more than 125% of that assumed in preparing the stock solution of the Unknown. In such a case, adjust its assumed potency accordingly and repeat the assay.

Microbial determinations of potency are subject to inter-assay as well as intra-assay variables, so that two or more independent assays are required for a reliable estimate of the potency of a given assay preparation or Unknown. Starting with separately prepared stock solutions and test dilutions of both the Standard and the Unknown, repeat the assay of a given Unknown on a different day. If the estimated potency of the second assay differs significantly, as indicated by the calculated standard error, from that of the first, conduct one or more additional assays. The combined result of a series of smaller, independent assays spread over a number of days is a more reliable estimate of potency than that from a single large assay with the same total number of plates or tubes.

##### Cylinder-Plate Method

To prepare assay plates using Petri dishes, place 21 mL of Medium 2 in each of the required number of plates, and allow it to harden into a smooth base layer of uniform depth, except for *Amphotericin B* and *Nystatin*, where no separate base layer is used. For *Erythromycin*, *Gentamicin*, *Neomycin B*, *Paromomycin*, and *Sisomicin*, use Medium 11. For *Bleomycin*, use 10 mL of Medium 35. For *Dihydrostreptomycin* use Medium 5. For *Vancomycin*, use 10 mL of Medium 8. For *Carbenicillin*, *Colistimethate Sodium*, *Colistin*, and *Polymyxin B*, use [Medium 9](#). For *Netilmicin*, use 20 mL of Medium 11. Add 4 mL of seed layer inoculum (see Preparation of Inoculum and [Table 3](#)), prepared as directed for the given antibiotic, except for *Bleomycin* (use 6 mL), for *Netilmicin* (use 5 mL), and for *Nystatin* and *Amphotericin B* (use 8 mL), tilting the plate back and forth to spread the inoculum evenly over the surface, and allow it to harden. Drop six assay cylinders on the inoculated surface from a height of 12 mm, using a mechanical guide or other device to insure even spacing on a radius of 2.8 cm, and cover the plates to avoid contamination. After filling the six cylinders on each plate with dilutions of antibiotic containing the test levels specified below, incubate the plates at 32° to 35°, or at the temperature specified below for the individual case, for 16 to 18 hours, remove the cylinders, and measure and record the diameter of each zone of growth inhibition to the nearest 0.1 mm. Incubate the plates at 29° to 31° for *Amphotericin B* and *Nystatin*. Incubate at 34° to 36° for *Novobiocin*. Incubate at 36° to 37.5° for *Carbenicillin*, *Colistimethate Sodium*, *Colistin*, *Dihydrostreptomycin*, *Gentamicin*, *Neomycin*, *Netilmicin*, *Paromomycin*, *Polymyxin B*, *Sisomicin*, and *Vancomycin*.

For the 1-level assay with a standard curve, prepare dilutions representing five test levels of the Standard (S1 to S5) and a single test level of the Unknown U3 corresponding to S3 of the standard curve, as defined under Preparation of the Standard and Preparation of the Sample. For deriving the standard curve, fill alternate cylinders on each of three plates with the median test dilution (S3) of the Standard and each of the remaining nine cylinders with one of the other four dilutions of the Standard. Repeat the process for the three dilutions of the Standard. For each Unknown, fill alternate cylinders on each of three plates with the median test dilution of the Standard (S3), and the remaining nine cylinders with the corresponding test dilution (U3) of the Unknown.

##### Turbidimetric Method

On the day of the assay, prepare the necessary doses by dilution of stock solutions of the Standard and of each Unknown as defined under Preparation of the Standard and Preparation of the Sample. Add 1.0 mL of each dose, except for *Gramicidin*, *Thiostrepton*, and *Tylosin* (use 0.10 mL) to each of 3 prepared test tubes, and place the 3 replicate tubes in a position, selected at random, in a test tube rack or other carrier. Include similarly in each rack 1 or 2 control tubes containing 1 mL of the test diluent (see Table 1) but no antibiotic. Upon completion of the rack of test solutions (with *Candididin*, within 30 minutes of the time when water is added to the dimethyl sulfoxide stock solution), add 9.0 mL of inoculum to each tube in the rack in turn, and place the completed rack immediately in an incubator or a water bath maintained at 36° to 37.5°, except for *Candididin* (incubate at 27° to 29°). Incubate the tubes for 4 to 5 hours, except for *Capreomycin*, *Chloramphenicol*, *Cycloserine*, *Dihydrostreptomycin*, *Spectinomycin*, *Streptomycin*, and *Troleandomycin* (incubate for 3 to 4 hours), *Tylosin* (incubate for 3 to 5 hours), and *Candididin* (incubate for 16 to 18 hours). After incubation add 0.5 mL of dilute formaldehyde to each tube, except for *Tylosin* (heat the rack in a water bath at 80° to 90° for 2 to 6 minutes or in a steam bath for 5 to 10 minutes, and bring to room temperature), taking one rack at a time, and read its transmittance or absorbance in a suitable spectrophotometer fitted with a 530-nm or 580-nm filter (see Spectrophotometer under Apparatus).

For the 1-level assay with a standard curve, prepare dilutions representing 5 test levels of the Standard (S1 to S5) and a single test level (U3) of each of up to 20 Unknowns corresponding to S3 of the Standard. Prepare also an extra S3 as a test of growth. Add 1 mL of each test dilution, except for *Gramicidin*, *Thiostrepton*, and *Tylosin* (use 0.10 mL) to 3 tubes and 1 mL of antibiotic-free diluent to 6 tubes as controls. Distribute one complete set, including 2 tubes of controls, to a tube rack, intermingling them at random. Add 9.0 mL of inoculum, except for *Thiostrepton* (use 10.0 mL of inoculum), incubate, add 0.5 mL of dilute formaldehyde, and complete the assay as directed above. Determine the exact duration of incubation by observation of growth in the reference concentration (median dose) of the dilutions of the Standard (S3).

#### CALCULATION

To calculate the potency from the data obtained either by the cylinder-plate or by the turbidimetric method, proceed in each case as directed under Potencies Interpolated from a

standard Curve (see [Design and Analysis of Biological Assays](#) (111)), using a log transformation, straight-line method with a least-squares fitting procedure, and a test for linearity. Where a number of assays of the same material are made with the same standard curve, calculate the coefficient of variation of results of all of the assays of the material. Where more than one assay is made of the same material with different standard curves, average the two or more values of the potency.

Auxiliary Information— Please [check for your question in the FAQs](#) before contacting USP.

### 85 BACTERIAL ENDOTOXINS TEST

◆ Portions of this general chapter have been harmonized with the corresponding texts of the European Pharmacopoeia and/or the Japanese Pharmacopoeia. Those portions that are not harmonized are marked with symbols (◆◆) to specify this fact.◆

This chapter provides a test to detect or quantify bacterial endotoxins that may be present in or on the sample of the article(s) to which the test is applied. It uses Limulus Amebocyte Lysate (LAL) obtained from the aqueous extracts of circulating amebocytes of horseshoe crab (Limulus polyphemus or Tachypleus tridentatus) which has been prepared and characterized for use as an LAL Reagent.◆◆

There are two types of techniques for this test: the gel-clot techniques, which are based on gel formation, and the photometric techniques. The latter include a turbidimetric method, which is based on the development of turbidity after cleavage of an endogenous substrate, and a chromogenic method, which is based on the development of color after cleavage of a synthetic peptide-chromogen complex. Proceed by any one of these techniques, unless otherwise indicated in the monograph. In case of dispute, the final decision is based on the gel-clot techniques, unless otherwise indicated in the monograph.

In the gel-clot techniques, the reaction endpoint is determined from dilutions of the material under test in direct comparison with parallel dilutions of a reference endotoxin, and quantities of endotoxin are expressed in USP Endotoxin Units (USP-EU). [note—One USP-EU is equal to one IU of endotoxin.]

Because LAL Reagents have been formulated to be used also for turbidimetric or colorimetric tests, such tests may be used to comply with the requirements. These tests require the establishment of a standard regression curve; the endotoxin content of the test material is determined by interpolation from the curve. The procedures include incubation for a preselected time of reacting endotoxin and control solutions with LAL Reagent and reading of the spectrophotometric light absorbance at suitable wavelengths. In the endpoint turbidimetric procedure the reading is made immediately at the end of the incubation period. In the endpoint colorimetric procedure the reaction is arrested at the end of the preselected time by the addition of an enzyme reaction-terminating agent prior to the readings. In the turbidimetric and colorimetric kinetic assays the absorbance is measured throughout the reaction period and rate values are determined from those readings.

#### APPARATUS AND GLASSWARE

Depyrogenate all glassware and other heat-stable materials in a hot-air oven using a validated process.◆◆ Commonly used minimum time and temperature settings are 30 minutes at 250°. If employing plastic apparatus, such as microplates and pipet tips for automatic pipettors, use only that which has been shown to be free of detectable endotoxin and not to interfere with the test. [note—In this chapter, the term “tube” includes any other receptacle such as a micro-titer well.]

#### PREPARATION OF THE STANDARD ENDOTOXIN STOCK SOLUTION AND STANDARD SOLUTIONS

The [USP Endotoxin RS](#) has a defined potency of 10,000 USP Endotoxin Units (EU) per vial. Constitute the entire contents of 1 vial of the RSE with 5 mL of LAL Reagent Water◆◆, mix intermittently for 30 minutes, using a vortex mixer, and use this concentrate for making appropriate serial dilutions. Preserve the concentrate in a refrigerator for making subsequent dilutions for not more than 14 days. Mix vigorously, using a vortex mixer, for not less than 3 minutes before use. Mix each dilution for not less than 30 seconds before proceeding to make the next dilution. Do not store dilutions, because of loss of activity by adsorption, in the absence of supporting data to the contrary.

#### Preparatory Testing

Use an LAL Reagent of confirmed label sensitivity.

The validity of test results for bacterial endotoxins requires an adequate demonstration that specimens of the article or of solutions, washings, or extracts thereof to which the test is to be applied do not of themselves inhibit or enhance the reaction or otherwise interfere with the test. Validation is accomplished by performing the inhibition or enhancement test described under each of the three techniques indicated. Appropriate negative controls are included. Validation must be repeated if the LAL Reagent source or the method of manufacture or formulation of the article is changed.

#### Preparation of Sample Solutions

Prepare sample solutions by dissolving or diluting drugs or extracting medical devices using LAL Reagent Water. Some substances or preparations may be more appropriately dissolved, diluted, or extracted in other aqueous solutions. If necessary, adjust the pH of the solution (or dilution thereof) to be examined so that the pH of the mixture of the LAL Reagent and sample falls within the pH range specified by the LAL Reagent manufacturer. This usually applies to a product with a pH in the range of 6.0 to 8.0. The pH may be adjusted using an acid, base, or suitable buffer as recommended by the LAL Reagent manufacturer. Acids and bases may be prepared from concentrates or solids with LAL Reagent Water in containers free of detectable endotoxin. Buffers must be validated to be free of detectable endotoxin and interfering factors.

#### DETERMINATION OF MAXIMUM VALID DILUTION (MVD)

The Maximum Valid Dilution is the maximum allowable dilution of a specimen at which the endotoxin limit can be determined. It applies to injections or to solutions for parenteral administration in the form constituted or diluted for administration, or, where applicable, to the amount of drug by weight if the volume of the dosage form for administration could be varied. The general equation to determine MVD is:

$$MVD = (\text{Endotoxin limit} \times \text{Concentration of sample solution}) / \lambda$$

where the concentration of sample solution and  $\lambda$  are as defined below. Where the endotoxin limit concentration is specified in the individual monograph in terms of volume (in EU per mL), divide the limit by  $\lambda$ , which is the labeled sensitivity (in EU per mL) of the LAL Reagent, to obtain the MVD factor. Where the endotoxin limit concentration is specified in the individual monograph in terms of weight or Units of active drug (in EU per mg or in EU per Unit), multiply the limit by the concentration (in mg per mL or in Units per mL) of the drug in the solution tested or of the drug constituted according to the label instructions, whichever is applicable, and divide the product of the multiplication by  $\lambda$ , to obtain the MVD factor. The MVD factor so obtained is the limit dilution factor for the preparation for the test to be valid.

#### ESTABLISHMENT OF ENDOTOXIN LIMITS

The endotoxin limit for parenteral drugs, defined on the basis of dose, is equal to  $K/M$ ,◆◆ where  $K$  is the threshold human pyrogenic dose of endotoxin per kg of body weight, and  $M$  is equal to the maximum recommended human dose of product per kg of body weight in a single hour period.

The endotoxin limit for parenteral drugs is specified in individual monographs in units such as EU/mL, EU/mg, or EU/Unit of biological activity.

## GEL-CLOT TECHNIQUES

The gel-clot techniques detect or quantify endotoxins based on clotting of the LAL Reagent in the presence of endotoxin. The concentration of endotoxin required to cause the lysate to clot under standard conditions is the labeled sensitivity of the LAL Reagent. To ensure both the precision and validity of the test, tests for confirming the labeled LAL Reagent sensitivity and for interfering factors are described under Preparatory Testing for the Gel-Clot Techniques.

### Preparatory Testing for the Gel-Clot Techniques

Test for Confirmation of Labeled LAL Reagent Sensitivity— Confirm the labeled sensitivity using at least 1 vial of the LAL Reagent lot. Prepare a series of two-fold dilutions of the [USP Endotoxin RS](#) in LAL Reagent Water to give concentrations of  $2\lambda$ ,  $\lambda$ ,  $0.5\lambda$ , and  $0.25\lambda$ , where  $\lambda$  is as defined above. Perform the test on the four standard concentrations in quadruplicate and include negative controls. The test for confirmation of lysate sensitivity is to be carried out when a new batch of LAL Reagent is used or when there is any change in the experimental conditions that may affect the outcome of the test.

Mix a volume of the LAL Reagent with an equal volume (such as 0.1-mL aliquots) of one of the standard solutions in each test tube. When single test vials or ampuls containing lyophilized LAL Reagent are used, add solutions directly to the vial or ampul. Incubate the reaction mixture for a constant period according to directions of the LAL Reagent manufacturer (usually at  $37 \pm 1^\circ$  for  $60 \pm 2$  minutes), avoiding vibration. To test the integrity of the gel, take each tube in turn directly from the incubator and invert it through about  $180^\circ$  in one smooth motion. If a firm gel has formed that remains in place upon inversion, record the result as positive. A result is negative if an intact gel is not formed. The test is not valid unless the lowest concentration of the standard solutions shows a negative result in all replicate tests.

The endpoint is the last positive test in the series of decreasing concentrations of endotoxin. Calculate the mean value of the logarithms of the endpoint concentration and then the antilogarithm of the mean value using the following equation:

$$\text{Geometric Mean Endpoint Concentration} = \text{antilog}(\Sigma e / f)$$

where  $\Sigma e$  is the sum of the log endpoint concentrations of the dilution series used, and  $f$  is the number of replicate test tubes. The geometric mean endpoint concentration is the measured sensitivity of the LAL Reagent (in EU/mL). If this is not less than  $0.5\lambda$  and not more than  $2\lambda$ , the labeled sensitivity is confirmed and is used in tests performed with this lysate.

Interfering Factors Test for the Gel-Clot Techniques— Prepare solutions A, B, C, and D as shown in [Table 1](#), and perform the inhibition/enhancement test on the sample solutions at a dilution less than the MVD, not containing any detectable endotoxins, following the procedure in the Test for Confirmation of Labeled LAL Reagent Sensitivity above. The geometric mean endpoint concentrations of solutions B and C are determined using the equation in that test.

Table 1. Preparation of Solutions for the Inhibition/Enhancement Test for Gel-Clot Techniques

Solution	Endotoxin Concentration/Solution to which Endotoxin is Added	Diluent	Dilution Factor	Initial Endotoxin Concentration	Number of Replicates
A <sup>a</sup>	none/sample solution	—	—	—	4
B <sup>b</sup>	$2\lambda$ /sample solution	sample solution	1	$2\lambda$	4
			2	$1\lambda$	4
			4	$0.5\lambda$	4
			8	$0.25\lambda$	4
C <sup>c</sup>	$2\lambda$ /water for BET	LAL Reagent Water	1	$2\lambda$	2
			2	$1\lambda$	2
			4	$0.5\lambda$	2
			8	$0.25\lambda$	2
D <sup>d</sup>	none/LAL Reagent Water	—	—	—	2

a Solution A: a sample solution of the preparation under test that is free of detectable endotoxins.

b Solution B: test for interference.

c Solution C: control for labeled LAL Reagent sensitivity.

d Solution D: negative control of LAL Reagent Water.

This test must be repeated when any condition that is likely to influence the test results changes. The test is not valid unless Solutions A and D show no reaction and the result of Solution C confirms the labeled sensitivity.

If the sensitivity of the lysate determined in the presence of the sample solution under test of Solution B is not less than  $0.5\lambda$  and not greater than  $2\lambda$ , the sample solution does not contain factors which interfere under the experimental conditions used. Otherwise, the sample solution to be examined interferes with the test.

If the sample under test does not comply with the test at a dilution less than the MVD, repeat the test using a greater dilution, not exceeding the MVD. The use of a more sensitive lysate permits a greater dilution of the sample to be examined and this may contribute to the elimination of interference.

Interference may be overcome by suitable treatment, such as filtration, neutralization, dialysis, or heating. To establish that the chosen treatment effectively eliminates interference without loss of endotoxins, perform the assay described below using the preparation to be examined to which [USP Endotoxin RS](#) has been added and which has been subjected to the selected treatment.

### Gel-Clot Limit Test

This test is used when a monograph contains a requirement for endotoxin limits.

Procedure— Prepare Solutions A, B, C, and D as shown in [Table 2](#), and perform the test on these solutions following the procedure in the Test for Confirmation of Labeled LAL Reagent Sensitivity under Preparatory Testing for the Gel-Clot Techniques.

Table 2. Preparation of Solutions for the Gel-Clot Limit Test

Solution*	Endotoxin Concentration/Solution to which Endotoxin is Added	Number of Replicates
A	none/diluted sample solution	2
B	$2\lambda$ /diluted sample solution	2
C	$2\lambda$ /LAL Reagent Water	2
D	none/LAL Reagent Water	2

\* Prepare Solution A and positive product control Solution B using a dilution not greater than the MVD and treatments as directed in the Interfering Factors Test for the Gel-Clot Techniques under Preparatory Testing for the Gel-Clot Techniques. Positive control Solutions B and C contain the standard endotoxin preparation at a concentration corresponding to twice the labeled LAL Reagent sensitivity. The negative control Solution D is LAL Reagent Water.

...terpretation— The test is not valid unless both replicates of positive control Solutions B and C are positive and those of negative control Solution D are negative. The preparation under test complies with the test when a negative result is found for both tubes containing Solution A. The preparation under test does not comply with the test when a positive result is found for both tubes containing Solution A.

Repeat the test when a positive result is found for 1 tube containing Solution A and a negative result for the other one. The preparation under test complies with the test when a negative result is found for both tubes containing Solution A in the repeat result. If the test is positive for the preparation under test at a dilution less than the MVD, the test may be repeated at a dilution not greater than the MVD.

#### Gel-Clot Assay

This assay quantifies bacterial endotoxins in sample solutions by titration to an endpoint.

Procedure— Prepare Solutions A, B, C, and D as shown in [Table 3](#), and test these solutions by following the procedure in the Test for Confirmation of Labeled LAL Reagent Sensitivity under Preparatory Testing for the Gel-Clot Techniques.

Table 3. Preparation of Solutions for the Gel-Clot Assay

Solution	Endotoxin Concentration/Solution to which Endotoxin is Added	Diluent	Dilution Factor	Initial Endotoxin Concentration	Number of Replicates
A <sup>a</sup>	none/sample solution	LAL Reagent Water	1	—	2
			2	—	2
			4	—	2
			8	—	2
B <sup>b</sup>	2 $\lambda$ /sample solution	—	1	2 $\lambda$	2
C <sup>c</sup>	2 $\lambda$ /LAL Reagent Water	LAL Reagent Water	1	2 $\lambda$	2
			2	1 $\lambda$	2
			4	0.5 $\lambda$	2
			8	0.25 $\lambda$	2
D <sup>d</sup>	none/LAL Reagent Water	—	—	—	2

a Solution A: a sample solution under test at the dilution, not to exceed the MVD, with which the Interfering Factors Test for the Gel-Clot Techniques was completed. Subsequent dilution of the sample solution must not exceed the MVD. Use LAL Reagent Water to make dilution series of four tubes containing the sample solution under test at concentrations of 1,  $\frac{1}{2}$ ,  $\frac{1}{4}$ , and  $\frac{1}{8}$  relative to the dilution with which the Interfering Factors Test for the Gel-Clot Techniques was completed. Other dilutions may be used as appropriate.

b Solution B: Solution A containing standard endotoxin at a concentration of 2 $\lambda$  (positive product control).

c Solution C: two series of 4 tubes of LAL Reagent Water containing the standard endotoxin at a concentration of 2 $\lambda$ ,  $\lambda$ , 0.5 $\lambda$ , and 0.25 $\lambda$ , respectively.

d Solution D: LAL Reagent Water (negative control).

Calculation and Interpretation— The test is not valid unless the following conditions are met: (1) both replicates of negative control Solution D are negative; (2) both replicates of positive product control Solution B are positive; and (3) the geometric mean endpoint concentration of Solution C is in the range of 0.5 $\lambda$  to 2 $\lambda$ .

To determine the endotoxin concentration of Solution A, calculate the endpoint concentration for each replicate series of dilutions by multiplying each endpoint dilution factor by  $\lambda$ . The endotoxin concentration in the sample is the geometric mean endpoint concentration of the replicates (see the formula given in the Test for Confirmation of Labeled LAL Reagent Sensitivity under Preparatory Testing for the Gel-Clot Techniques). If the test is conducted with a diluted sample solution, calculate the concentration of endotoxin in the original sample solution by multiplying by the dilution factor. If none of the dilutions of the sample solution is positive in a valid assay, report the endotoxin concentration as less than  $\lambda$  (if the diluted sample was tested, less than  $\lambda$  times the lowest dilution factor of the sample.) If all dilutions are positive, the endotoxin concentration is reported as equal to or greater than the greatest dilution factor multiplied by  $\lambda$  (e.g., initial dilution factor times 8 times  $\lambda$  in [Table 3](#)).

The article meets the requirements of the test if the concentration of endotoxin is less than that specified in the individual monograph.

#### PHOTOMETRIC TECHNIQUES

The turbidimetric method measures increases in turbidity. Depending on the test principle used, this technique is classified as either endpoint-turbidimetric or kinetic-turbidimetric. The endpoint-turbidimetric technique is based on the quantitative relationship between the concentration of endotoxins and the turbidity (absorbance or transmission) of the reaction mixture at the end of an incubation period. The kinetic-turbidimetric technique is a method to measure either the onset time needed to reach a predetermined absorbance of the reaction mixture or the rate of turbidity development.

The chromogenic method measures the chromophore released from a suitable chromogenic peptide by the reaction of endotoxins with the LAL Reagent. Depending on the test principle employed, this technique is classified as either endpoint-chromogenic or kinetic-chromogenic. The endpoint-chromogenic technique is based on the quantitative relationship between the concentration of endotoxins and the release of chromophore at the end of an incubation period. The kinetic-chromogenic technique is a method to measure either the onset time needed to reach a predetermined absorbance of the reaction mixture or the rate of color development.

All photometric tests are carried out at the incubation temperature recommended by the LAL Reagent manufacturer, which is usually 37  $\pm$  1°.

#### Preparatory Testing for the Photometric Techniques

To assure the precision or validity of the turbidimetric and chromogenic techniques, preparatory tests are conducted to verify that the criteria for the standard curve are valid and that the sample solution does not inhibit or enhance the reaction. Revalidation for the test method is required when conditions that are likely to influence the test result change.

Verification of Criteria for the Standard Curve— Using the Standard Endotoxin Solution, prepare at least three endotoxin concentrations to generate the standard curve. Perform the test using at least three replicates of each standard endotoxin concentration according to the manufacturer's instructions for the LAL Reagent (with regard to volume ratios, incubation time, temperature, pH, etc.). If the desired range in the kinetic methods is greater than two logs, additional standards should be included to bracket each log increase within the range of the standard curve. The absolute value of the correlation coefficient, |r|, must be greater than or equal to 0.980 for the range of endotoxin concentrations indicated by the manufacturer of the LAL Reagent.

Interfering Factors Test for the Photometric Techniques— Select an endotoxin concentration at or near the middle of the endotoxin standard curve. Prepare Solutions A, B, C, and D as shown in [Table 4](#). Perform the test on Solutions A, B, C, and D at least in duplicate following the instructions for the LAL Reagent used (with regard to volume of sample and LAL Reagent, volume ratio of sample to LAL Reagent, incubation time, etc.).

Table 4. Preparation of Solutions for the Inhibition/Enhancement Test for Photometric Techniques

Solution	Endotoxin Concentration	Solution to which Endotoxin is Added	Number of Replicates
A <sup>a</sup>	none	sample solution	not less than 2
B <sup>b</sup>	middle concentration of the standard curve	sample solution	not less than 2
C <sup>c</sup>	at least 3 concentrations (lowest concentration is designated $\lambda$ )	LAL Reagent Water	each not less than 2
D <sup>d</sup>	none	LAL Reagent Water	not less than 2

Solution A: the sample solution may be diluted not to exceed MVD.

- b Solution B: the preparation under test at the same dilution as Solution A, containing added endotoxin at a concentration equal to or near the middle of the standard curve.
- c Solution C: the standard endotoxin at the concentrations used in the validation of the method described in Verification of Criteria for the Standard Curve under Preparatory Testing for the Photometric Techniques (positive control series).
- d Solution D: LAL Reagent Water (negative control).

Calculate the mean recovery of the added endotoxin by subtracting the mean endotoxin concentration in the solution (if any) from that containing the added endotoxin. In order to be considered free of interfering factors under the conditions of the test, the measured concentration of the endotoxin added to the sample solution must be within 50% to 200% of the known added endotoxin concentration after subtraction of any endotoxin detected in the solution without added endotoxin.

When the endotoxin recovery is out of the specified ranges, the interfering factors must be removed as described in the Interfering Factors Test for the Gel-Clot Techniques under Preparatory Testing for the Gel-Clot Techniques. Repeating the Interfering Factors Test for the Gel-Clot Techniques validates the treatment.

#### Procedure for the Photometric Techniques

Follow the procedure described in the Interfering Factors Test for the Photometric Techniques under Preparatory Testing for the Photometric Techniques.

#### Calculation for the Photometric Techniques

Calculate the endotoxin concentration of each of the replicates of test Solution A using the standard curve generated by positive control series C. The test is not valid unless the following conditions are met: (1) the results of control series C comply with the requirements for validation defined under Verification of Criteria for the Standard Curve under Preparatory Testing for the Photometric Techniques; (2) the endotoxin recovery, calculated from the concentration found in Solution B after subtracting the endotoxin concentration found in Solution A is within 50 to 200%; and (3) the result of negative control series D does not exceed the limit of the blank value required in the description of the LAL Reagent used.

#### Interpretation of Results from the Photometric Techniques

In photometric assays, the preparation under test complies with the test if the mean endotoxin concentration of the replicates of Solution A, after correction for dilution and concentration, is less than the endotoxin limit for the product.

◆1 LAL Reagent reacts with some  $\beta$ -glucans in addition to endotoxins. Some preparations that are treated will not react with  $\beta$ -glucans and must be used for samples that contain glucans.◆

◆2 For a validity test of the procedure for inactivating endotoxins, see Dry-Heat Sterilization under [Sterilization and Sterility Assurance of Compendial Articles](#) (1211). Use an LAL Reagent having a sensitivity of not less than 0.15 Endotoxin Unit per mL.◆

◆3 Sterile Water for Injection or other water that shows no reaction with the specific LAL Reagent with which it is to be used, at the limit of sensitivity of such reagent.◆

◆4 K is 5 USP-EU/kg for any route of administration other than intrathecal (for which K is 0.2 USP-EU/kg body weight). For radiopharmaceutical products not administered intrathecally the endotoxin limit is calculated as 175/V, where V is the maximum recommended dose in mL. For intrathecally administered radiopharmaceuticals, the endotoxin limit is obtained by the formula 14/V. For formulations (usually anticancer products) administered on a per square meter of body surface, the formula is K/M, where K = 5 EU/kg and M is the (maximum dose/m<sup>2</sup>/hour  $\times$  1.80 m<sup>2</sup>)/70 Kg.◆

#### 87 BIOLOGICAL REACTIVITY TESTS, IN VITRO

The following tests are designed to determine the biological reactivity of mammalian cell cultures following contact with the elastomeric plastics and other polymeric materials with direct or indirect patient contact or of specific extracts prepared from the materials under test. It is essential that the tests be performed on the specified surface area. When the surface area of the specimen cannot be determined, use 0.1 g of elastomer or 0.2 g of plastic or other material for every mL of extraction fluid. Exercise care in the preparation of the materials to prevent contamination with microorganisms and other foreign matter.

Three tests are described (i.e., the Agar Diffusion Test, the Direct Contact Test, and the Elution Test).<sup>1</sup> The decision as to which type of test or the number of tests to be performed to assess the potential biological response of a specific sample or extract depends upon the material, the final product, and its intended use. Other factors that may also affect the suitability of sample for a specific use are the polymeric composition; processing and cleaning procedures; contacting media; inks; adhesives; absorption, adsorption, and permeability of preservatives; and conditions of storage. Evaluation of such factors should be made by appropriate additional specific tests before determining that a product made from a specific material is suitable for its intended use.

[USP Reference Standards](#) (11)—[USP High-Density Polyethylene RS](#). [USP Positive Bioreaction RS](#).

Cell Culture Preparation— Prepare multiple cultures of L-929 (ATCC cell line CCL 1, NCTC clone 929) mammalian fibroblast cells in serum-supplemented minimum essential medium having a seeding density of about 105 cells per mL. Incubate the cultures at 37  $\pm$  1° in a humidified incubator for not less than 24 hours in a 5  $\pm$  1% carbon dioxide atmosphere until a monolayer, with greater than 80% confluence, is obtained. Examine the prepared cultures under a microscope to ensure uniform, near-confluent monolayers. [note—The reproducibility of the In Vitro Biological Reactivity Tests depends upon obtaining uniform cell culture density.]

Extraction Solvents— [Sodium Chloride Injection](#) (see monograph—use Sodium Chloride Injection containing 0.9% of NaCl). Alternatively, serum-free mammalian cell culture media or serum-supplemented mammalian cell culture media may be used. Serum supplementation is used when extraction is done at 37° for 24 hours.

#### Apparatus—

Autoclave— Employ an autoclave capable of maintaining a temperature of 121  $\pm$  2°, equipped with a thermometer, a pressure gauge, a vent cock, a rack adequate to accommodate the test containers above the water level, and a water cooling system that will allow for cooling of the test containers to about 20°, but not below 20°, immediately following the heating cycle.

Oven— Use an oven, preferably a mechanical convection model, that will maintain operating temperatures in the range of 50° to 70° within  $\pm$  2°.

Incubator— Use an incubator capable of maintaining a temperature of 37  $\pm$  1° and a humidified atmosphere of 5  $\pm$  1% carbon dioxide in air.

Extraction Containers— Use only containers, such as ampuls or screw-cap culture test tubes, or their equivalent, of Type I glass. If used, culture test tubes, or their equivalent, are

Closed with a screw cap having a suitable elastomeric liner. The exposed surface of the elastomeric liner is completely protected with an inert solid disk 50 to 75  $\mu\text{m}$  in thickness. . . suitable disk can be fabricated from polytef.

**Preparation of Apparatus**— Cleanse all glassware thoroughly with chromic acid cleansing mixture and, if necessary, with hot nitric acid followed by prolonged rinsing with Sterile Water for Injection. Sterilize and dry by a suitable process containers and devices used for extraction, transfer, or administration of test material. If ethylene oxide is used as the sterilizing agent, allow not less than 48 hours for complete degassing.

#### Procedure—

Preparation of Sample for Extracts— Prepare as directed in the Procedure under [Biological Reactivity Tests, In Vivo](#) (88).

**Preparation of Extracts**— Prepare as directed for Preparation of Extracts in [Biological Reactivity Tests, In Vivo](#) (88) using either Sodium Chloride Injection (0.9% NaCl) or serum-free mammalian cell culture media as Extraction Solvents. [note—If extraction is done at 37° for 24 hours in an incubator, use cell culture media supplemented by serum. The extraction conditions should not in any instance cause physical changes, such as fusion or melting of the material pieces, other than a slight adherence.]

#### Agar Diffusion Test

This test is designed for elastomeric closures in a variety of shapes. The agar layer acts as a cushion to protect the cells from mechanical damage while allowing the diffusion of leachable chemicals from the polymeric specimens. Extracts of materials that are to be tested are applied to a piece of filter paper.

**Sample Preparation**— Use extracts prepared as directed or use portions of the test specimens having flat surfaces not less than 100  $\text{mm}^2$  in surface area.

Positive Control Preparation— Proceed as directed for Sample Preparation.

Negative Control Preparation— Proceed as directed for Sample Preparation.

**Procedure**— Using 7 mL of cell suspension prepared as directed under Cell Culture Preparation, prepare the monolayers in plates having a 60-mm diameter. Following incubation, aspirate the culture medium from the monolayers, and replace it with serum-supplemented culture medium containing not more than 2% of agar. [note—The quality of the agar must be adequate to support cell growth. The agar layer must be thin enough to permit diffusion of leached chemicals.] Place the flat surfaces of Sample Preparation, Negative Control Preparation, and Positive Control Preparation or their extracts in an appropriate extracting medium, in duplicate cultures in contact with the solidified agar surface. Use no more than three specimens per prepared plate. Incubate all cultures for not less than 24 hours at 37  $\pm$  1°, preferably in a humidified incubator containing 5  $\pm$  1% of carbon dioxide. Examine each culture around each Sample, Negative Control, and Positive Control, under a microscope, using a suitable stain, if desired.

**Interpretation of Results**— The biological reactivity (cellular degeneration and malformation) is described and rated on a scale of 0 to 4 (see [Table 1](#)). Measure the responses of the cell cultures to the Sample Preparation, the Negative Control Preparation, and the Positive Control Preparation. The cell culture test system is suitable if the observed responses to the Negative Control Preparation is grade 0 (no reactivity) and to the Positive Control Preparation is at least grade 3 (moderate). The Sample meets the requirements of the test if the response to the Sample Preparation is not greater than grade 2 (mildly reactive). Repeat the procedure if the suitability of the system is not confirmed.

Table 1. Reactivity Grades for Agar Diffusion Test and Direct Contact Test

Grade	Reactivity	Description of Reactivity Zone
0	None	No detectable zone around or under specimen
1	Slight	Some malformed or degenerated cells under specimen
2	Mild	Zone limited to area under specimen
3	Moderate	Zone extends 0.5 to 1.0 cm beyond specimen
4	Severe	Zone extends greater than 1.0 cm beyond specimen

#### Direct Contact Test

This test is designed for materials in a variety of shapes. The procedure allows for simultaneous extraction and testing of leachable chemicals from the specimen with a serum-supplemented medium. The procedure is not appropriate for very low- or high-density materials that could cause mechanical damage to the cells.

**Sample Preparation**— Use portions of the test specimen having flat surfaces not less than 100  $\text{mm}^2$  in surface area.

Positive Control Preparation— Proceed as directed for Sample Preparation.

Negative Control Preparation— Proceed as directed for Sample Preparation.

**Procedure**— Using 2 mL of cell suspension prepared as directed under Cell Culture Preparation, prepare the monolayers in plates having a 35-mm diameter. Following incubation, aspirate the culture medium from the cultures, and replace it with 0.8 mL of fresh culture medium. Place a single Sample Preparation, a Negative Control Preparation, and a Positive Control Preparation in each of duplicate cultures. Incubate all cultures for not less than 24 hours at 37  $\pm$  1° in a humidified incubator containing 5  $\pm$  1% of carbon dioxide. Examine each culture around each Sample, Negative Control, and Positive Control Preparation, either visually or under a microscope, using a suitable stain, if desired.

**Interpretation of Results**— Proceed as directed for Interpretation of Results under Agar Diffusion Test. The Sample meets the requirements of the test if the response to the Sample Preparation is not greater than grade 2 (mildly reactive). Repeat the procedure if the suitability of the system is not confirmed.

#### Elution Test

This test is designed for the evaluation of extracts of polymeric materials. The procedure allows for extraction of the specimens at physiological or nonphysiological temperatures for varying time intervals. It is appropriate for high-density materials and for dose-response evaluations.

**Sample Preparation**— Prepare as directed in Preparation of Extracts, using either Sodium Chloride Injection (0.9% NaCl) or serum-free mammalian cell culture media as Extraction Solvents. If the size of the Sample cannot be readily measured, a mass of not less than 0.1 g of elastomeric material or 0.2 g of plastic or polymeric material per mL of extraction medium may be used. Alternatively, use serum-supplemented mammalian cell culture media as the extracting medium to simulate more closely physiological conditions. Prepare the extracts by heating for 24 hours in an incubator containing 5  $\pm$  1% of carbon dioxide. Maintain the extraction temperature at 37  $\pm$  1°, because higher temperatures may cause denaturation of serum proteins.

Positive Control Preparation— Proceed as directed for Sample Preparation.

Negative Control Preparation— Proceed as directed for Sample Preparation.

**Procedure**— Using 2 mL of cell suspension prepared as directed under Cell Culture Preparation, prepare the monolayers in plates having a 35-mm diameter. Following incubation, aspirate the culture medium from the monolayers, and replace it with extracts of the Sample Preparation, Negative Control Preparation, or Positive Control Preparation. The serum-supplemented and serum-free cell culture media extracts are tested in duplicate without dilution (100%). The Sodium Chloride Injection extract is diluted with serum-supplemented cell culture medium and tested in duplicate at 25% extract concentration. Incubate all cultures for 48 hours at 37  $\pm$  1° in a humidified incubator preferably containing 5  $\pm$  1% of carbon dioxide. Examine each culture at 48 hours, under a microscope, using a suitable stain, if desired.

**Interpretation of Results**— Proceed as directed for Interpretation of Results under Agar Diffusion Test but using [Table 2](#). The Sample meets the requirements of the test if the response to the Sample Preparation is not greater than grade 2 (mildly reactive). Repeat the procedure if the suitability of the system is not confirmed. For dose-response evaluations, repeat the

procedure, using quantitative dilutions of the sample extract.

Table 2. Reactivity Grades for Elution Test

Grade	Reactivity	Conditions of all Cultures
0	None	Discrete intracytoplasmic granules; no cell lysis
1	Slight	Not more than 20% of the cells are round, loosely attached, and without intracytoplasmic granules; occasional lysed cells are present
2	Mild	Not more than 50% of the cells are round and devoid of intracytoplasmic granules; no extensive cell lysis and empty areas between cells
3	Moderate	Not more than 70% of the cell layers contain rounded cells or are lysed
4	Severe	Nearly complete destruction of the cell layers

\* Further details are given in the following publications of the American Society for Testing and Materials, 1916 Race St., Philadelphia, PA 19103: "Standard Test Method for Agar Diffusion Cell Culture Screening for Cytotoxicity," ASTM Designation F 895-84; "Standard Practice for Direct Contact Cell Culture Evaluation of Materials for Medical Devices," ASTM Designation F 813-83.

### 88 BIOLOGICAL REACTIVITY TESTS, IN VIVO

The following tests are designed to determine the biological response of animals to elastomers, plastics and other polymeric material with direct or indirect patient contact, or by the injection of specific extracts prepared from the material under test. It is essential to make available the specific surface area for extraction. When the surface area of the specimen cannot be determined, use 0.1 g of elastomer or 0.2 g of plastic or other material for every mL of extraction fluid. Also it is essential to exercise care in the preparation of the materials to be injected or instilled to prevent contamination with microorganisms and other foreign matter. Three tests are described. The Systemic Injection Test and the Intracutaneous Test are used for elastomeric materials, especially to elastomeric closures for which the appropriate [Biological Reactivity Tests, In Vitro](#) 87 have indicated significant biological reactivity.

These two tests are used for plastics and other polymers in addition to a third test, the Implantation Test, to test the suitability of these materials intended for use in fabricating containers and accessories thereto, for use in parenteral preparations, and for use in medical devices, implants, and other systems.

These three tests are applied to materials or medical devices, if there is a need for classification of plastics and other polymers based on in vivo biological reactivity testing.

For the purpose of this chapter, these definitions apply: the Sample is the specimen under test or an extract prepared from such a specimen. A Blank consists of the same quantity of the same extracting medium that is used for the extraction of the specimen under test, treated in the same manner as the extracting medium containing the specimen under test. A

Negative Control<sup>a</sup> is a specimen that gives no reaction under the conditions of the test.

Classification of Plastics— Six Plastic Classes are defined (see [Table 1](#)). This classification is based on responses to a series of in vivo tests for which extracts, materials, and routes of administration are specified. These tests are directly related to the intended end-use of the plastic articles. The choice of extractants is representative of the vehicles in preparations with which the plastics are likely to be in contact. The [Table 1](#) classification facilitates communication among suppliers, users, and manufacturers of plastics by summarizing the tests to be performed for containers for injections and medical devices if a need for classification exists.

Table 1. Classification of Plastics

Plastic Classes <sup>a</sup>						Tests To Be Conducted			
I	II	III	IV	V	VI	Test Material	Animal	Dose	Procedure <sup>b</sup>
x	x	x	x	x	x	Extract of Sample in Sodium	Mouse	50 mL/kg	A (iv)
x	x	x	x	x	x	Chloride Injection	Rabbit	0.2 mL/animal at each of 10 sites	B
x	x	x	x	x	x	Extract of Sample in 1 in 20	Mouse	50 mL/kg	A (iv)
x	x	x	x	x	x	Solution of Alcohol in Sodium Chloride Injection	Rabbit	0.2 mL/animal at each of 10 sites	B
x		x	x			Extract of Sample in	Mouse	10 g/kg	A (ip)
		x	x			Polyethylene Glycol 400	Rabbit	0.2 mL/animal at each of 10 sites	B
x	x	x	x			Extract of Sample in	Mouse	50 mL/kg	A (ip)
	x	x	x			Vegetable Oil	Rabbit	0.2 mL/animal at each of 10 sites	B
x		x				Implant strips of Sample	Rabbit	4 strips/animal	C

a Tests required for each class are indicated by "x" in appropriate columns.

b Legend: A (ip)—Systemic Injection Test (intraperitoneal); A (iv)—Systemic Injection Test (intravenous); B—Intracutaneous Test (intracutaneous); C—Implantation Test (intramuscular implantation).

With the exception of the Implantation Test, the procedures are based on the use of extracts that, depending on the heat resistance of the material, are prepared at one of three standard temperatures: 50°, 70°, and 121°. Therefore, the class designation of a plastic must be accompanied by an indication of the temperature of extraction (e.g., IV-121°, which represents a class IV plastic extracted at 121°, or I-50°, which represents a class I plastic extracted at 50°).

Plastics may be classified as USP Plastic Classes I–VI only on the basis of the response criteria prescribed in [Table 1](#).

This classification does not apply to plastics that are intended for use as containers for oral or topical products, or that may be used as an integral part of a drug formulation. [Table 1](#) does not apply to natural elastomers, which are to be tested in Sodium Chloride Injection and vegetable oils only.

The Systemic Injection Test and the Intracutaneous Test are designed to determine the systemic and local, respectively, biological responses of animals to plastics and other polymers by the single-dose injection of specific extracts prepared from a Sample. The Implantation Test is designed to evaluate the reaction of living tissue to the plastic and other polymers by the implantation of the Sample itself into animal tissue. The proper preparation and placement of the specimens under aseptic conditions are important in the conduct of the Implantation Test.

These tests are designed for application to plastics and other polymers in the condition in which they are used. If the material is to be exposed to any cleansing or sterilization process prior to its end-use, then the tests are to be conducted on a Sample prepared from a specimen preconditioned by the same processing.

actors such as material composition, processing and cleaning procedures, contacting media, inks, adhesives, absorption, adsorption and permeability of preservatives, and condition of storage may also affect the suitability of a material for a specific use. Evaluation of such factors should be made by appropriate additional specific tests to determine the suitability of a material for its intended use.

USP Reference Standards  USP High-Density Polyethylene RS.

**Extracting Media—**

sodium chloride injection (see monograph). Use Sodium Chloride Injection containing 0.9% of NaCl.

1 in 20 solution of alcohol in Sodium Chloride Injection.

polyethylene glycol 400 (see monograph).

vegetable oil— Use freshly refined Sesame Oil (see monograph) or Cottonseed Oil (see monograph) or other suitable vegetable oils.

drug product vehicle (where applicable).

water for injection (see monograph).

**note—**The Sesame Oil or Cottonseed Oil or other suitable vegetable oil meets the following additional requirements. Obtain, if possible, freshly refined oil. Use three properly prepared animals and inject the oil intracutaneously in a dose of 0.2 mL into each of 10 sites per animal, and observe the animals at 24, 48, and 72 hours following injection. Rate the observations at each site on the numerical scale indicated in Table 2. For the 3 rabbits (30 injection sites), at any observation time, the average response for erythema is not greater than 0.5 and for edema is not greater than 1.0, and no site shows a tissue reaction larger than 10 mm in overall diameter. The residue of oil at the injection site should not be misinterpreted as edema. Edematous tissue blanches when gentle pressure is applied.

Table 2. Evaluation of Skin Reactions

Erythema and Eschar Formation	Score
No erythema	0
Very slight erythema (barely perceptible)	1
Well-defined erythema	2
Moderate to severe erythema	3
Severe erythema (beet-redness) to slight eschar formation (injuries in depth)	4
Edema Formation <sup>*</sup>	Score
No edema	0
Very slight edema (barely perceptible)	1
Slight edema (edges of area well defined by definite raising)	2
Moderate edema (raised approximately 1 mm)	3
Severe edema (raised more than 1 mm and extending beyond the area of exposure)	4

\* Excludes noninflammatory (mechanical) edema from the blank or extraction fluid.

**Apparatus—** The apparatus for the tests includes the following.

**AUTOCLAVE—** Use an autoclave capable of maintaining a temperature of  $121 \pm 2.0^\circ$ , equipped with a thermometer, a pressure gauge, a vent cock, a rack adequate to accommodate the test containers above the water level, and a water cooling system that will allow for cooling of the test containers to about, but not below,  $20^\circ$  immediately following the heating cycle.

**OVEN—** Use an oven, preferably a forced-circulation model, that will maintain operating temperatures of  $50^\circ$  or  $70^\circ$  within  $\pm 2^\circ$ .

**EXTRACTION CONTAINERS—** Use only containers, such as ampuls or screw-cap culture test tubes, of Type I glass. If used, culture test tubes are closed with screw caps having suitable elastomeric liners. The exposed surface of the elastomeric liner is completely protected with an inert solid disk 0.05 mm to 0.075 mm in thickness. A suitable disk may be fabricated from a polytef resin.

**Preparation of Apparatus—** Cleanse all glassware thoroughly with chromic acid cleansing mixture, or if necessary with hot nitric acid, followed by prolonged rinsing with water. Clean cutting utensils by an appropriate method (e.g., successive cleaning with acetone and methylene chloride) prior to use in subdividing a specimen. Clean all other equipment by thorough scrubbing with a suitable detergent and prolonged rinsing with water.

Render containers and equipment used for extraction, and in transfer and administration of test material, sterile and dry by a suitable process. [note—If ethylene oxide is used as the sterilizing agent, allow adequate time for complete degassing.]

**Procedure—**

**preparation of sample—** Both the Systemic Injection Test and the Intracutaneous Test may be performed using the same extract, if desired, or separate extracts may be made for each test. Select and subdivide into portions a Sample of the size indicated in Table 3. Remove particulate matter, such as lint and free particles, by treating each subdivided Sample or Negative Control as follows: place the Sample into a clean, glass-stoppered, 100-mL graduated cylinder of Type I glass, and add about 70 mL of Water for Injection. Agitate for about 30 seconds, and drain off the water, repeat this step, and dry those pieces prepared for the extraction with Vegetable Oil in an oven at a temperature not exceeding  $50^\circ$ . [note—Do not clean the Sample with a dry or wet cloth or by rinsing or washing with an organic solvent, surfactant, etc.]

Table 3. Surface Area of Specimen To Be Used<sup>1</sup>

Form of Material	Thickness	Amount of Sample for Each 20 mL of Extracting Medium	Subdivided Into
Film or sheet	<0.5 mm	Equivalent of 120 cm <sup>2</sup> total surface area (both sides combined)	Strips of about 5 x 0.3 cm
	0.5 to 1 mm	Equivalent of 60 cm <sup>2</sup> total surface area (both sides combined)	
Tubing	<0.5 mm (wall)	Length (in cm) = 120 cm <sup>2</sup> /(sum of ID and OD circumferences)	Sections of about 5 x 0.3 cm
	0.5 to 1 mm (wall)	Length (in cm) = 60 cm <sup>2</sup> /(sum of ID and OD circumferences)	
Slabs, tubing, and molded items	>1 mm	Equivalent of 60 cm <sup>2</sup> total surface area (all exposed surfaces combined)	Pieces up to about 5 x 0.3 cm
Elastomers	>1 mm	Equivalent of 25 cm <sup>2</sup> total surface area (all exposed surfaces combined)	Do not subdivide <sup>2</sup>

<sup>1</sup> When surface area cannot be determined due to the configuration of the specimen, use 0.1 g of elastomer or 0.2 g of plastic or other polymers for every 1 mL of extracting fluid.

<sup>2</sup> Molded elastomeric closures are tested intact.

**preparation of extracts—** Place a properly prepared Sample to be tested in an extraction container, and add 20 mL of the appropriate extracting medium. Repeat these directions for

each extracting medium required for testing. Also prepare one 20-mL blank of each medium for parallel injections and comparisons. Extract by heating in an autoclave at 121° for 60 minutes, in an oven at 70° for 24 hours, or at 50° for 72 hours. Allow adequate time for the liquid within the container to reach the extraction temperature. [note—The extraction conditions should not in any instance cause physical changes such as fusion or melting of the Sample pieces, which result in a decrease in the available surface area. A slight adherence of the pieces can be tolerated. Always add the cleaned pieces individually to the extracting medium. If culture tubes are used for autoclave extractions with Vegetable Oil, seal screw caps adequately with pressure-sensitive tape.]

Cool to about room temperature but not below 20°, shake vigorously for several minutes, and decant each extract immediately, using aseptic precautions, into a dry, sterile vessel. Store the extracts at a temperature between 20° and 30°, and do not use for tests after 24 hours. Of importance are the contact of the extracting medium with the available surface area of the plastic and the time and temperature during extraction, the proper cooling, agitation, and decanting process, and the aseptic handling and storage of the extracts following extraction.

#### Systemic Injection Test

This test is designed to evaluate systemic responses to the extracts of materials under test following injection into mice.

**Test Animal**— Use healthy, not previously used albino mice weighing between 17 and 23 g. For each test group use only mice of the same source. Allow water and food, commonly used for laboratory animals and of known composition, *ad libitum*.

**Procedure**— [note—Agitate each extract vigorously prior to withdrawal of injection doses to ensure even distribution of the extracted matter. However, visible particulates should not be injected intravenously.] Inject each of the five mice in a test group with the Sample or the Blank as outlined in [Table 4](#), except to dilute each g of the extract of the Sample prepared with Polyethylene Glycol 400, and the corresponding blank, with 4.1 volumes of Sodium Chloride Injection to obtain a solution having a concentration of about 200 mg of polyethylene glycol per mL.

**Table 4. Injection Procedure—Systemic Injection Test**

Extract or Blank	Dose per kg	Route*	Injection Rate, $\mu\text{L}$ per second
Sodium Chloride Injection	50 mL	IV	100
1 in 20 solution of Alcohol in Sodium Chloride Injection	50 mL	IV	100
Polyethylene Glycol 400	10 g	IP	—
Drug product vehicle	50 mL	IV	100
(where applicable)	50 mL	IP	—
Vegetable Oil	50 mL	IP	—

\* IV = intravenous (aqueous sample and blank); IP = intraperitoneal (oleaginous sample and blank).

Observe the animals immediately after injection, again 4 hours after injection, and then at least at 24, 48, and 72 hours. If during the observation period none of the animals treated with the extract of the Sample shows a significantly greater biological reactivity than the animals treated with the Blank, the Sample meets the requirements of this test. If two or more mice die, or if abnormal behavior such as convulsions or prostration occurs in two or more mice, or if a body weight loss greater than 2 g occurs in three or more mice, the Sample does not meet the requirements of the test. If any animals treated with the Sample show only slight signs of biological reactivity, and not more than one animal shows gross symptoms of biological reactivity or dies, repeat the test using groups of 10 mice. On the repeat test, all 10 animals treated with the Sample show no significant biological reactivity above the Blank animals during the observation period.

#### Intracutaneous Test

This test is designed to evaluate local responses to the extracts of materials under test following intracutaneous injection into rabbits.

**Test Animal**— Select healthy, thin-skinned albino rabbits whose fur can be clipped closely and whose skin is free from mechanical irritation or trauma. In handling the animals, avoid touching the injection sites during observation periods, except to discriminate between edema and an oil residue. [note—Rabbits previously used in unrelated tests, such as the [Pyrogen Test](#) (151), and that have received the prescribed rest period, may be used for this test provided that they have clean, unblemished skin.]

**Procedure**— [note—Agitate each extract vigorously prior to withdrawal of injection doses to ensure even distribution of the extracted matter.] On the day of the test, closely clip the fur on the animal's back on both sides of the spinal column over a sufficiently large test area. Avoid mechanical irritation and trauma. Remove loose hair by means of vacuum. If necessary, swab the skin lightly with diluted alcohol, and dry the skin prior to injection. More than one extract from a given material can be used per rabbit, if you have determined that the test results will not be affected. For each Sample use two animals and inject each intracutaneously, using one side of the animal for the Sample and the other side for the Blank, as outlined in [Table 5](#). [note—Dilute each g of the extract of the Sample prepared with Polyethylene Glycol 400, and the corresponding Blank, with 7.4 volumes of Sodium Chloride Injection to obtain a solution having a concentration of about 120 mg of polyethylene glycol per mL.]

**Table 5. Intracutaneous Test**

Extract or Blank	Number of Sites (per animal)	Dose, $\mu\text{L}$ per site
Sample	5	200
Blank	5	200

Examine injection sites for evidence of any tissue reaction such as erythema, edema, and necrosis. Swab the skin lightly, if necessary, with diluted alcohol to facilitate reading of injection sites. Observe all animals at 24, 48, and 72 hours after injection. Rate the observations on a numerical scale for the extract of the Sample and for the Blank, using [Table 2](#). Reclip the fur as necessary during the observation period. The average erythema and edema scores for Sample and Blank sites are determined at every scoring interval (24, 48, and 72 hours) for each rabbit. After the 72 hour scoring, all erythema scores plus edema scores are totalled separately for each Sample and Blank. Divide each of the totals by 12 (2 animals  $\times$  3 scoring periods  $\times$  2 scoring categories) to determine the overall mean score for each Sample versus each corresponding Blank. The requirements of the test are met if the difference between the Sample and the Blank mean score is 1.0 or less. If at any observation period the average reaction to the Sample is questionably greater than the average reaction to the Blank, repeat the test using three additional rabbits. The requirements of the test are met if the difference between the Sample and the Blank mean score is 1.0 or less.

#### Implantation Test

The implantation test is designed for the evaluation of plastic materials and other polymeric materials in direct contact with living tissue. Of importance are the proper preparation of the implant strips and their proper implantation under aseptic conditions. Prepare for implantation 8 strips of the Sample and 4 strips of USP High-Density Polyethylene RS. Each strip should measure not less than 10  $\times$  1 mm. The edges of the strips should be as smooth as possible to avoid additional mechanical trauma upon implantation. Strips of the specified minimum size are implanted by means of a hypodermic needle (15- to 19-gauge) with intravenous point and a sterile trocar. Use either presterilized needles into which the sterile plastic strips are aseptically inserted, or insert each clean strip into a needle, the cannula and hub of which are protected with an appropriate cover, and then subjected to the appropriate sterilization procedure. [note—Allow for proper degassing if agents such as ethylene oxide are used.]

**Test Animal**— Select healthy, adult rabbits weighing not less than 2.5 kg, and whose paravertebral muscles are sufficiently large in size to allow for implantation of the test strips. Do not use any muscular tissue other than the paravertebral site. The animals must be anesthetized with a commonly used anesthetic agent to a degree deep enough to prevent muscular movements, such as twitching.

**Procedure**— Perform the test in a clean area. On the day of the test or up to 20 hours before testing, clip the fur of the animals on both sides of the spinal column. Remove loose hair by means of vacuum. Swab the skin lightly with diluted alcohol and dry the skin prior to injection.

Implant four strips of the Sample into the paravertebral muscle on one side of the spine of each of two rabbits, 2.5 to 5 cm from the midline and parallel to the spinal column, and about 2.5 cm apart from each other. In a similar fashion implant two strips of USP High-Density Polyethylene RS, in the opposite muscle of each animal. Insert a sterile stylet into the needle to hold the implant strip in the tissue while withdrawing the needle. If excessive bleeding is observed after implantation of a strip, place a duplicate strip at another site.

Keep the animals for a period of not less than 120 hours, and sacrifice them at the end of the observation period by administering an overdose of an anesthetic agent or other suitable agents. Allow sufficient time to elapse for the tissue to be cut without bleeding. Examine macroscopically the area of the tissue surrounding the center portion of each implant strip. Use a magnifying lens and auxiliary light source. Observe the Sample and Control implant sites for hemorrhage, necrosis, discolorations, and infections, and record the observations.

Measure encapsulation, if present, by recording the width of the capsule (from the periphery of the space occupied by the implant Control or Sample to the periphery of the capsule) rounded to the nearest 0.1 mm. Score encapsulation according to [Table 6](#).

Table 6. Evaluation of Encapsulation in the Implantation Test

Capsule Width	Score
None	0
up to 0.5 mm	1
0.6–1.0 mm	2
1.1–2.0 mm	3
Greater than 2.0 mm	4

Calculate the differences between average scores for the Sample and Control sites. The requirements of the test are met if the difference does not exceed 1.0, or if the difference between the Sample and Control mean scores for more than one of the four implant sites does not exceed 1 for any implanted animal.

#### SAFETY TESTS—BIOLOGICALS

The safety test set forth here is intended to detect in an article any unexpected, unacceptable biological reactivity. This *in vivo* test is provided for the safety assessment of biologics (see [Biologics](#) 1041) and biotechnology-derived products.

##### Safety Test

Select five healthy mice not previously used for testing, weighing between 17 and 23 g, unless otherwise directed in the individual monograph or elsewhere in this chapter, and maintained on an adequate balanced diet. Prepare a test solution as directed in the individual monograph. Unless otherwise directed in the individual monograph or elsewhere in this chapter, inject intravenously a dose of 0.5 mL of the test solution into each of the mice, using a 26-gauge needle of suitable length, or of the length specified below as applicable. Observe the animals over the 48 hours following the injection. If, at the end of 48 hours, all of the animals survive and not more than one of the animals shows outward symptoms of a reaction not normally expected of the level of toxicity related to the article, the requirements of this test are met. If one or more animals die or if more than one of the animals shows signs of abnormal or untoward toxicity of the article under test, repeat the test using at least another 10 mice similar to those used in the initial test, but weighing  $20 \pm 1$  g. In either case, if all of the animals survive for 48 hours and show no symptoms of a reaction indicative of an abnormal or undue level of toxicity of the article, the requirements of the test are met.

For biologics, perform the test according to the procedures prescribed in the Federal Regulations (see [Biologics](#) 1041), Section 610.11, using not less than two mice similar to those described above but weighing less than 22 g and not less than two healthy guinea pigs weighing less than 400 g. Unless otherwise directed in the individual monograph, for a liquid product or a freeze-dried product that has been constituted as directed in the labeling, inject a volume of 0.5 mL intraperitoneally into each mouse, and inject a volume of 5.0 mL intraperitoneally into each guinea pig. For freeze-dried products for which the volume of constitution is not indicated in the label, or for nonliquid products other than freeze-dried products, perform the test using the route of administration, test dose, and diluent approved by the Center for Biologics Evaluation and Research (FDA), on the basis of substantial evidence demonstrating that the test variation will assure sensitivity equal to or greater than that of the test described above. Observe the animals for a minimum observation period of 7 days. If all of the animals survive the test period, do not exhibit any response that is not specific for or expected from the product and that may indicate a difference in such product quality, and weigh no less at the end of the test period than at the time of injection, the requirements of the test are met. If the article fails to meet the requirements, the test may be repeated as in the initial test, in the one or both species in which the requirements were not met. If the animals fulfill the criteria specified for the initial test, the article meets the requirements of the test. If the article fails to meet the requirements after the first repeat test, and not less than 50% of the total number of animals of the species in which the requirements of the test were not met in the combined initial and first retests have survived, a second retest may be performed. Use twice the number of animals of the relevant species used in the initial test. If the animals fulfill the criteria specified for the initial test, the requirements of the test are met.

#### 91 CALCIUM PANTOTHENATE ASSAY

USP Reference Standards 11—[USP Calcium Pantothenate RS](#)

Standard Stock Solution of Calcium Pantothenate— Dissolve 50 mg of [USP Calcium Pantothenate RS](#), previously dried and stored in the dark over phosphorus pentoxide and accurately weighed while protected from absorption of moisture during the weighing, in about 500 mL of water in a 1000-mL volumetric flask. Add 10 mL of 0.2 N acetic acid and 100 mL of sodium acetate solution (1 in 60), then dilute with water to volume. Each mL represents 50 µg of [USP Calcium Pantothenate RS](#). Store under toluene in a refrigerator.

Standard Preparation— On the day of the assay, dilute a measured volume of Standard Stock Solution of Calcium Pantothenate with sufficient water so that it contains, in each mL, between 0.01 µg and 0.04 µg of calcium pantothenate, the exact concentration being such that the responses obtained as directed for Procedure, 2.0 and 4.0 mL of the Standard Preparation being used, are within the linear portion of the log-concentration response curve.

Assay Preparation— Proceed as directed in the individual monograph for preparing a solution expected to contain approximately the equivalent of the calcium pantothenate concentration in the Standard Preparation.

Basal Medium Stock Solution—	
Acid-hydrolyzed Casein Solution	25 mL
Cystine-Tryptophane Solution	25 mL
Polysorbate 80 Solution	0.25 mL
Dextrose, Anhydrous	10 g
Sodium Acetate, Anhydrous	5 g
Adenine-Guanine-Uracil Solution	5 mL
Riboflavin-Thiamine Hydrochloride-Biotin Solution	5 mL
Para-aminobenzoic Acid-Niacin-Pyridoxine Hydrochloride Solution	5 mL
Salt Solution A	5 mL
Salt Solution B	5 mL

Dissolve the anhydrous dextrose and sodium acetate in the solutions previously mixed, and adjust with 1 N sodium hydroxide to a pH of 6.8. Finally, dilute with water to 250 mL, and mix.

Acid-Hydrolyzed Casein Solution— Mix 100 g of vitamin-free casein with 500 mL of 6 N hydrochloric acid, and reflux the mixture for 8 to 12 hours. Remove the hydrochloric acid from the mixture by distillation under reduced pressure until a thick paste remains. Redissolve the resulting paste in water, adjust the solution with 1 N sodium hydroxide to a pH of  $3.5 \pm 0.1$ , and add water to make 1000 mL. Add 20 g of activated charcoal, stir for 1 hour, and filter. Repeat the treatment with activated charcoal. Store under toluene in a refrigerator at a temperature not below  $10^\circ$ . Filter the solution if a precipitate forms during storage.

Cystine-Tryptophane Solution— Suspend 4.0 g of L-cystine and 1.0 g of L-tryptophane (or 2.0 g of D,L-tryptophane) in 700 to 800 mL of water, heat to  $70^\circ$  to  $80^\circ$ , and add dilute hydrochloric acid (1 in 2) dropwise, with stirring, until the solids are dissolved. Cool, and add water to make 1000 mL. Store under toluene in a refrigerator at a temperature not below  $10^\circ$ .

Adenine-Guanine-Uracil Solution— Dissolve 200 mg each of adenine sulfate, guanine hydrochloride, and uracil, with the aid of heat, in 10 mL of 4 N hydrochloric acid, cool, and add water to make 200 mL. Store under toluene in a refrigerator.

Polysorbate 80 Solution— Dissolve 25 g of polysorbate 80 in alcohol to make 250 mL.

Riboflavin-Thiamine Hydrochloride-Biotin Solution— Prepare a solution containing, in each mL, 20  $\mu$ g of riboflavin, 10  $\mu$ g of thiamine hydrochloride, and 0.04  $\mu$ g of biotin, by dissolving riboflavin, thiamine hydrochloride, and biotin in 0.02 N acetic acid. Store, protected from light, under toluene in a refrigerator.

Para-aminobenzoic Acid-Niacin-Pyridoxine Hydrochloride Solution— Prepare a solution in neutral 25 percent alcohol to contain 10  $\mu$ g of para-aminobenzoic acid, 50  $\mu$ g of niacin, and 40  $\mu$ g of pyridoxine hydrochloride in each mL. Store in a refrigerator.

Salt Solution A— Dissolve 25 g of monobasic potassium phosphate and 25 g of dibasic potassium phosphate in water to make 500 mL. Add 5 drops of hydrochloric acid, and store under toluene.

Salt Solution B— Dissolve 10 g of magnesium sulfate, 0.5 g of sodium chloride, 0.5 g of ferrous sulfate, and 0.5 g of manganese sulfate in water to make 500 mL. Add 5 drops of hydrochloric acid, and store under toluene.

Stock Culture of Lactobacillus plantarum— Dissolve 2.0 g of water-soluble yeast extract in 100 mL of water, add 500 mg of anhydrous dextrose, 500 mg of anhydrous sodium acetate, and 1.5 g of agar, and heat the mixture, with stirring, on a steam bath, until the agar dissolves. Add approximately 10-mL portions of the hot solution to test tubes, suitably close or cover the tubes, sterilize at  $121^\circ$ , and allow the tubes to cool in an upright position. Prepare stab cultures in 3 or more of the tubes, using a pure culture of Lactobacillus plantarum, incubating for 16 to 24 hours at any selected temperature between  $30^\circ$  and  $37^\circ$  but held constant to within  $\pm 0.5^\circ$ , and finally store in a refrigerator. Prepare a fresh stab of the stock culture every week, and do not use for inoculum if the culture is more than 1 week old.

Culture Medium— To each of a series of test tubes containing 5.0 mL of Basal Medium Stock Solution add 5.0 mL of water containing 0.2  $\mu$ g of calcium pantothenate. Plug the tubes with cotton, sterilize in an autoclave at  $121^\circ$ , and cool.

Inoculum— Make a transfer of cells from the stock culture of Lactobacillus plantarum to a sterile tube containing 10 mL of culture medium. Incubate this culture for 16 to 24 hours at any selected temperature between  $30^\circ$  and  $37^\circ$  but held constant to within  $\pm 0.5^\circ$ . The cell suspension so obtained is the inoculum.

Procedure— To similar test tubes add, in duplicate, 1.0 and/or 1.5, 2.0, 3.0, 4.0, and 5.0 mL, respectively, of the Standard Preparation. To each tube and to 4 similar tubes containing no Standard Preparation add 5.0 mL of Basal Medium Stock Solution and sufficient water to make 10 mL.

To similar test tubes add, in duplicate, volumes of the Assay Preparation corresponding to 3 or more of the levels listed above for the Standard Preparation, including the levels of 2.0, 3.0, and 4.0 mL. To each tube add 5.0 mL of the Basal Medium Stock Solution and sufficient water to make 10 mL. Place one complete set of Standard and Assay tubes together in one tube rack and the duplicate set in a second rack or section of a rack, preferably in random order.

Cover the tubes of both series suitably to prevent contamination, and heat in an autoclave at  $121^\circ$  for 5 minutes. Cool, add 1 drop of inoculum to each tube, except 2 of the 4 tubes containing no Standard Preparation (to serve as the uninoculated blanks), and mix. Incubate the tubes at a temperature between  $30^\circ$  and  $37^\circ$ , held constant to within  $\pm 0.5^\circ$  until, following 16 to 24 hours of incubation, there has been no substantial increase in turbidity in the tubes containing the highest level of standard during a 2-hour period.

Determine the transmittance of the tubes in the following manner: Mix the contents of each tube, and transfer to an optical container if necessary. Place the container in a spectrophotometer that has been set at a specific wavelength between 540 nm and 660 nm, and read the transmittance when a steady state is reached. This steady state is observed a few seconds after agitation when the galvanometer reading remains constant for 30 seconds or more. Allow approximately the same time interval for the reading on each tube.

With the transmittance set at 1.00 for the uninoculated blank, read the transmittance of the inoculated blank. With the transmittance set at 1.00 for the inoculated blank, read the transmittance for each of the remaining tubes. If there is evidence of contamination with a foreign microorganism, disregard the result of the assay.

Calculation— Prepare a standard concentration-response curve as follows. For each level of the standard, calculate the response from the sum of the duplicate values of the

transmittance as the difference,  $y = 2.00 - \Sigma$  (of transmittance). Plot this response on the ordinate of cross-section paper against the logarithm of the mL of Standard Preparation per tube on the abscissa, using for the ordinate either an arithmetic or a logarithmic scale, whichever gives the better approximation to a straight line. Draw the straight line or smooth curve that best fits the plotted points.

Calculate the response,  $y$ , adding together the two transmittances for each level of the Assay Preparation. Read from the standard curve the logarithm of the volume of the Standard Preparation corresponding to each of those values of  $y$  that fall within the range of the lowest and highest points plotted for the standard. Subtract from each logarithm so obtained the logarithm of the volume, in mL, of the Assay Preparation to obtain the difference,  $x$ , for each dosage level. Average the values of  $x$  for each of three or more dosage levels to obtain  $x = M'$ , the log-relative potency of the Assay Preparation. Determine the quantity, in mg, of [USP Calcium Pantothenate RS](#) corresponding to the calcium pantothenate in the portion of material taken for assay as antilog:

$$M = \text{antilog}(M' + \log R)$$

in which  $R$  is the number of mg of calcium pantothenate that was assumed to be present in each mg (or capsule or tablet) of the material taken for assay.

Replication— Repeat the entire determination at least once, using separately prepared Assay Preparations. If the difference between the two log-potencies  $M$  is not greater than 0.08, their mean,  $M$ , is the assayed log-potency of the test material (see [The Confidence Interval and Limits of Potency](#) 111). If the two determinations differ by more than 0.08, conduct one or more additional determinations. From the mean of two or more values of  $M$  that do not differ by more than 0.15, compute the mean potency of the preparation under assay.

\* American Type Culture Collection No. 8014 is suitable. This strain formerly was known as *Lactobacillus arabinosus* 17-5.

### 111 DESIGN AND ANALYSIS OF BIOLOGICAL ASSAYS

#### General

The potency of several Pharmacopeial drugs must be determined by bioassay. A controlling factor in assay design and analysis is the variability of the biological test system, which may vary in its mean response from one laboratory to another, and from time to time in the same laboratory. To control this type of variation, the response to a Pharmacopeial drug is compared with a USP Reference Standard or other suitable standard. For convenience, each such preparation will be called the "Standard" and each preparation under assay, or Sample, the "Unknown," and these will be designated respectively by the symbols S and U. (The Sample is sometimes referred to as the "test preparation.")

After elimination of extraneous variables from the comparison of the Standard and the Unknown, an error variance is computed from the remaining variation, which, while uncontrolled, can nevertheless be measured. The error variance is required in calculating the confidence interval of the assayed potency. The confidence interval, known also as the fiducial interval, is so computed that its upper and lower limits are expected to enclose the true potency of the Unknown in 19 out of 20 assays. Many assay procedures fix the acceptable width of the confidence interval, and two or more independent assays may be needed to meet the specified limit. The confidence limits of the individual component assays usually overlap.

The aim of this chapter is to present a concise account of biometrical procedures for the USP bioassays. Its various sections are interrelated. Although the procedures are planned primarily for the assay of a single Unknown, equations for the joint assay of several Unknowns are given in context throughout the chapter and are summarized in the last section. Proof that an assayed potency meets its required confidence limits may be based also upon other recognized biometric methods that have a precision equivalent to that of the methods outlined herein.

A glossary of the terms used in the equations is provided at the end of this chapter.

#### Steps Preceding the Calculation of Potency

Designs for Minimizing the Error Variance— Variation in response is reduced as much as is practicable by the limitations imposed on body weight, age, previous handling, environment, and similar factors. In a number of assays, the test animals or their equivalent are then assigned at random but in equal numbers to the different doses of the Standard and Unknown. This implies an objective random process, such as throwing dice, shuffling cards, or using a table of random numbers. Assigning the same number of individuals to each treatment simplifies the subsequent calculations materially, and usually leads to the shortest confidence interval for a given number of observations.

In some assays, the potential responses can be assembled into homogeneous sets in advance of treatment. The differences between sets are later segregated, so that they do not affect adversely either the computed potency or its confidence interval. One unit within each set, picked at random, receives each treatment. Examples of randomized sets are the cleared areas on a single plate in the plate assay of an antibiotic, and four successive paired readings in the same rat in the Vasopressin Injection assay. Sets of two occur where each test animal is used twice, as in the assays of Tubocurarine Chloride Injection and Insulin Injection. In these cases, neither the average differences between individuals nor the order of treatment can bias the potency or precision. In the microbial assays for vitamin B12 activity and for calcium pantothenate, replicate tubes are assigned to two or more separate, complete sets, preferably with the tubes arranged at random within each set. This restricts the variation due to position or order within a set to the differences within each complete replicate.

Rejection of Outlying or Aberrant Observations— A response that is questionable because of failure to comply with the procedure during the course of an assay is rejected. Other aberrant values may be discovered only after the responses have been tabulated, but can then be traced to assay irregularities, which justify their omission. The arbitrary rejection or retention of an apparently aberrant response can be a serious source of bias. In general, the rejection of observations solely on the basis of their relative magnitudes is a procedure to be used sparingly. When this is unavoidable, each suspected aberrant response or outlier may be tested against one of two criteria:

1. The first criterion is based upon the variation within a single group of supposedly equivalent responses. On the average, it will reject a valid observation once in 25 or once in 50 trials, provided that relatively few, if any, responses within the group are identical. Beginning with the supposedly erratic value or outlier, designate the responses in order of magnitude from  $y_1$  to  $y_N$ , where  $N$  is the number of observations in the group. Compute the relative gap  $G_1 = (y_2 - y_1)/(y_N - y_1)$  when  $N = 3$  to 7,  $G_2 = (y_3 - y_1)/(y_N - y_1)$  when  $N = 8$  to

13, or  $G_3 = (y_3 - y_1)/(y_N - y_1)$  when  $N = 14$  to 24. If  $G_1$ ,  $G_2$ , or  $G_3$  exceeds the critical value in [Table 1](#) for the observed  $N$ , there is a statistical basis for omitting the outlier.

Table 1

Test for outliers. In samples from a normal population, gaps equal to or larger than the following values of  $G_1$ ,  $G_2$ , and  $G_3$  occur with a probability  $P = 0.02$  where outliers can occur only at one end, or with  $P = 0.04$  where they may occur at either end.

N	3	4	5	6	7				
$G_1$	.976	.846	.729	.644	.586				
N	8	9	10	11	12	13			
$G_2$	.780	.725	.678	.638	.605	.578			
N	14	15	16	17	18	19	20	21	22
$G_3$	.602	.579	.559	.542	.527	.514	.502	.491	.481
									.472
									.464

This criterion is applicable also in a microbial assay where each treatment is represented by a transmittance in each of two separate complete sets. Subtract each transmittance in the first set from its paired value in the second set, and record each difference with its sign, either plus or minus. Beginning with the most divergent difference, designate the  $N$  differences in order of magnitude from  $y_1$  to  $y_N$  and compute the relative gap  $G_1$ ,  $G_2$ , or  $G_3$ . If this exceeds its critical value in [Table 1](#), one of the two transmittances giving the aberrant difference is suspect and may be identified on inspection or by comparison with its expectation (see next column). Repeat the process with the remaining differences if an outlier is suspected in a second pair.

2. The second criterion compares the ranges from a series of  $k = 2$  or more groups. Different groups may receive different treatments, but all  $f$  responses within each group represent the same treatment. Compute the range from each group by subtracting the smallest response from the largest within each of the  $k$  groups. Divide the largest of the  $k$  ranges by the sum of all the ranges in the series. Refer this ratio  $R^*$  to [Table 2](#). If  $k$  is not larger than 10, use the tabular values in the upper part of [Table 2](#); if  $k$  is larger than 10, multiply  $R^*$  by  $(k + 2)$  and interpolate, if necessary, between the tabular values in the lower part of [Table 2](#). If  $R^*$  exceeds the tabular or interpolated value, the group with the largest range is suspect and inspection of its components will usually identify the observation, which is then assumed to be aberrant or an outlier. The process may be repeated with the remaining ranges if an outlier is suspected in a second group.

Table 2

Test for groups containing outliers. Compute the range from the  $f$  observations in each of  $k$  groups, where all groups in the series are equal in size. The observed ratio  $R^*$  of the largest range to the sum of the  $k$  ranges will equal or exceed the following critical values at a probability of  $P = 0.05$ .

No. of	Critical $R^*$ for Ranges Each from $f$ Observations								
	Ranges $k$	2	3	4	5	6	7	8	9
2	0.962	0.862	0.803	0.764	0.736	0.717	0.702	0.691	0.682
3	.813	.667	.601	.563	.539	.521	.507	.498	.489

Replacement of Missing Values— As directed in the monographs and in this section, the calculation of potency and its confidence interval from the total response for each dose of each preparation requires the same number of observations in each total. When observations are lost or additional responses have been obtained with the Standard, the balance may be restored by one of the following procedures, so that the usual equations apply.

1. Reduce the number of observations in the larger groups until the number of responses is the same for each treatment. If animals have been assigned at random to each treatment group, either omit one or more responses, selected at random, from each larger group, or subtract the mean of each larger group from its initial total as often as may be necessary. The latter technique is preferred when extra animals have been assigned deliberately to the Standard. When the assay consists of randomized sets, retain only the complete sets.
2. Alternatively, an occasional smaller group may be brought up to size when the number of missing responses is not more than one in any one treatment or 10% in the entire assay. Estimate a replacement for each missing value by either method a or method b. One degree of freedom ( $n$ ) is lost from the error variance  $s^2$  for each replacement by either method, except in a microbial assay where each response is based on the sum of two or more transmittances and only one transmittance is replaced.

(a) If animals have been assigned to treatments at random, add the mean of the remaining responses in the incomplete group to their total. In a microbial assay, when one of two transmittances is missing for a given treatment, add the mean difference between sets, computed from all complete pairs, to the remaining transmittance to obtain the replacement.

(b) If the assay consists of randomized sets, replace the missing value by

$$y' = \frac{fT'_r + kT'_t - T'}{(f-1)(k-1)}, \quad (1)$$

where  $f$  is the number of sets,  $k$  is the number of treatments or doses, and  $T'_r$ ,  $T'_t$ , and  $T'$  are the incomplete totals for the randomized set, treatment, and assay from which an observation is missing.

If the assay consists of  $n'$  Latin squares with  $k$  rows in common, replace a missing value by

$$y' = \frac{k(n'T'_c + T'_r + T'_t) - 2T'}{(k-1)(n'k-2)} \quad (1a)$$

where  $n'$  is the number of Latin squares with  $k$  rows in common,  $K$  is the number of treatments or doses, and  $T_c$ ,  $Tr$ ,  $Tt$ , and  $T'$  are respectively the incomplete totals for the column row, treatment, and assay from which an observation is missing.

If more than one value is missing, substitute the treatment mean temporarily in all but one of the empty places, and compute  $y'$  for the other by Equation 1. Replace each of the initial substitutions in turn by Equation 1, and repeat the process in successive approximations until a stable  $y'$  is obtained for each missing observation.

#### Calculation of Potency from a Single Assay

Directions for calculating potency from the data of a single assay are given in the individual monographs. In those assays that specify graphical interpolation from dosage-response curves but that meet the conditions for assay validity set forth herein, potency may be computed alternatively by the appropriate method in this section.

Planning the assay involves assigning to the Unknown an assumed potency, to permit administering it in dosages equivalent to those of the Standard. The closer the agreement between this original assumption and the result of the assay, the more precise is the calculated potency. The ratio of a given dose of the Standard, in  $\mu\text{g}$  or in USP Units, to the corresponding dose of the Unknown, measured as specified in the monograph, is designated uniformly by  $R$ . The log-relative potency in quantities assumed initially to equal those of the Standard is designated as  $M'$ .

Ideally,  $M'$  should not differ significantly from zero. The log-potency is

$$M = M' + \log R \quad (2)$$

or

$$\text{Potency} = P_* = \text{antilog } M = (\text{antilog } M')R$$

Assay from Direct Determinations of the Threshold Dose—Tubocurarine Chloride Injection and Metocurarine Iodide are assayed from the threshold dose that just produces a characteristic biological response. The ratio of the mean threshold dose for the Standard to that for the Unknown gives the potency directly. The threshold dose is determined twice in each animal, once with the Standard and once with the Unknown. Each dose is converted to its logarithm, the difference ( $x$ ) between the two log-doses is determined for each animal, and potency is calculated from the average of these differences.

In the [Bacterial Endotoxins Test](#) (85), the geometric mean dilution endpoint for the Unknown corresponding to the geometric mean dilution endpoint for the Standard (multiplied by a dilution factor, where applicable) gives the concentration of endotoxin in the test material.

In these assays, the confidence interval depends upon the variability in the threshold dose.

Indirect Assays from the Relationship between the Log-Dose and the Response—Generally, the threshold dose cannot be measured directly; therefore, potency is determined indirectly by comparing the responses following known doses of the Standard with the responses following one or more similar doses of the Unknown. Within a restricted dosage range, a suitable measure of the response usually can be plotted as a straight line against the log-dose, a condition that simplifies the calculation of potency and its confidence interval. Both the slope and position of the log-dose response relationship are determined in each assay by the use of two or more levels of the Standard, or, preferably, of both the Standard and the Unknown.

In the assay of Heparin Sodium, the interval between the dose at which clotting occurs and that which produces no clotting is so small that the dosage-response curve is not determined explicitly. Moving averages are used instead to interpolate the log-dose corresponding to 50% clotting for both the Standard and the Unknown, leading to the log-potency (see Calculation under Heparin Sodium). The precision of the potency is estimated from the agreement between independent assays of the same Unknown.

For a drug that is assayed biologically, the response should plot as a straight line against the log-dose over an adequate range of doses. Where a preliminary test is required or the assay depends upon interpolation from a multi-dose Standard curve, plot on coordinate paper the mean response of the Standard at each dosage level on the ordinate against the log-dose  $x$  on the abscissa. If the trend is basically linear over the required dosage range, the initial response unit may be used directly as  $y$ ; if, instead, the trend is clearly curvilinear, a suitable transformation of each initial reading may bring linearity.

One possible transformation is to logarithms; another, in microbial tube assays, where  $y = (100 - \% \text{ transmittance})$  does not plot linearly against the log-dose  $x$ , is to probits. In this case, if absorbance cannot be read directly, the percent transmittance for each tube or test solution is first converted to absorbance,  $A = 2 - \log(\% \text{ transmittance})$ . Each absorbance value, in turn, is converted to % reduction in bacterial growth as

$$\% \text{ reduction} = 100(\bar{A}_c - A)/\bar{A}_c$$

where  $A_c$  is the mean density for the control tubes (without antibiotic or with excess of vitamin) in the same set or tube rack. Percent reduction is then transformed to a probit (see [Table 3](#)) to obtain a new  $y$  for all later calculation. The probit transformation offers the advantage of extending the working range of linearity even where a portion of the dosage-response relationship is nonlinear in the original units of percent transmittance, provided that the incubation period does not extend beyond the logarithmic phase of growth of the control tubes.

Table 3

Probits (normal deviates + 5) corresponding to percentages in the margins.

	0	1	2	3	4	5	6	7	8	9

The LD<sub>50</sub> in the Safety test for [Iron Dextran Injection](#) is calculated with log-doses and probits. The four doses of the Injection, in mg of iron per kg of body weight, are transformed to  $x_1 = 2.574$ ,  $x_2 = 2.699$ ,  $x_3 = 2.875$ , and  $x_4 = 3.000$ . The probits corresponding to the number of deaths observed in each group of 10 mice are designated  $y_1$ ,  $y_2$ ,  $y_3$ , and  $y_4$ , respectively, and are given in [Table 3](#) for mortalities from 10 to 90 percent. For observed deaths of 0 and 10 adjacent to doses giving an intermediate mortality, use the approximate probits 3.02 and 6.98, respectively; omit the end value (at  $x_1$  or  $x_4$ ) if not adjacent to an intermediate mortality. Since the information in a probit varies with its expectation, assign each probit an approximate relative weight  $w$  for computing the LD<sub>50</sub> of the Injection, as shown in the accompanying table.

No. of Deaths	0 or 10	1 or 9	2 or 8	3 or 7	4 to 6
Weight, w	0.3	0.7	1.0	1.2	1.3

Calculate the weighted means

$$\bar{x} = \Sigma(wx)/\Sigma w$$

and (2a)

$$\bar{y} = \Sigma(wy)/\Sigma w$$

from the sum of the weights,  $\Sigma w$ , of the four (or three) acceptable responses and the corresponding weighted sums of the log-doses,  $\Sigma(wx)$ , and of the probits,  $\Sigma(wy)$ . From the sums of the weighted products,  $\Sigma(wxy)$ , and of the weighted squares,  $\Sigma(wx^2)$ , compute the slope  $b$  of the log-dose-probit line as

$$b = \frac{\Sigma(wxy) - \bar{x}\Sigma(wy)}{\Sigma(wx^2) - \bar{x}\Sigma(wx)} \quad (2b)$$

The LD<sub>50</sub> for this safety test, in mg of iron per kg of body weight, is calculated as

$$LD_{50} = \text{antilog}[\bar{x} + (5 - \bar{y})/b] \quad (2c)$$

In quantal assays not included in this Pharmacopeia, such as the mouse assay for insulin, the calculation with probits involves other adjustments that are omitted here.

When the mean response  $y_t$  for each dose of Standard plots linearly against the log-dose, and the  $k$  doses are spaced at equal intervals on the logarithmic scale, the predicted responses ( $Y_L$  and  $Y_H$ ) at the extreme ends of the line of best fit can be computed directly with the coefficients  $x^*$  in [Table 4](#), which correspond to the  $k$  successive log-doses, as

$$Y_L = \Sigma(x_*\bar{y}_i)/\text{divisor}$$

and (3)

$$Y_H = \Sigma(x_*\bar{y}_i)/\text{divisor}$$

where  $\Sigma$  stands uniformly for "the sum of" the values that follow it. When  $Y_L$  and  $Y_H$  are plotted against the low and high log-doses,  $X_L$  and  $X_H$ , respectively, they may be connected by a straight line with the slope

$$b = (Y_H - Y_L)/(X_H - X_L) \quad (4)$$

At any selected log-dose  $x$  of Standard, the predicted response is

$$Y = \bar{y} + b(x - \bar{x}) \quad (5)$$

where  $x = \Sigma x/k$ , and  $y = (Y_L + Y_H)/2$ , or, for predictions within a set,  $y$  is the mean response for the Standard within the set.

Table 4

Coefficients  $x^*$  for computing the responses  $Y_L$  and  $Y_H$  predicted by least squares at the lowest and highest of  $k$  log-doses when these are spaced at equal intervals.

No. of Doses	Predicted	Coefficient $x^*$ for Mean Response $y_t$ at Log-Dose						Divisor
		1	2	3	4	5	6	
3	$Y_L$	5	2	-1				6
	$Y_H$	-1	2	5				
4	$Y_L$	7	4	1	-2			10
	$Y_H$	-2	1	4	7			
5	$Y_L$	3	2	1	0	-1		5
	$Y_H$	-1	0	1	2	3		
6	$Y_L$	11	8	5	2	-1	-4	21
	$Y_H$	-4	-1	2	5	8	11	

When the log-dose response relationship is linear, but the  $k$  doses (expressed in mL) are spaced substantially in an arithmetic sequence as in [Table 5](#) (which refers to the microbial assays set forth under [Antibiotics—Microbial Assays](#) [81](#)), the slope  $b$  of the straight line of best fit may be computed with the terms in [Table 5](#) and the mean response at each dose  $y_t$ , or  $T_t = f(y_t)$  where the number of  $y_t$ 's is constant at each dose, as

$$b = \Sigma(x_1\bar{y}_i)/e_b'i = \Sigma(x_1T_i)/fe_b'i \quad (6)$$

The coefficients  $x_1$  are convenient multiples of the differences  $(x - \bar{x})$  about the mean log-dose  $x$ , and  $e_b'i$  is the corresponding multiple of  $\Sigma(x - \bar{x})^2$ . The predicted response  $Y$  at a given log-dose  $x$  may be computed by substitution of the assay slope  $b$  in Equation 5 and of the mean  $y$  either of all the responses on the Standard in the entire assay or of those for each set separately.

Table 5

Coefficients  $x_1$  for computing the slope  $b$  of a log-dose response curve when the doses are spaced on an arithmetic scale as shown.

No. of Doses	1	1.5	2	3	4	5	Divisor $e_b'i$	Mean Log-Dose $x$
4	—	-29	-12	12	29	—	14.4663	0.38908
5	-34	—	-9	5	15	23	24.7827	0.41584
5	—	-20	-11	2	11	18	13.3249	0.45105
6	-15	-8	-3	4	9	13	14.1017	0.37588

potencies interpolated from a standard curve— Where the log-dose response curve of the Standard in a given assay is curvilinear and is fitted graphically to the plotted points, the amount of Standard that would be expected to produce each observed response  $y$  of an Unknown is estimated by interpolation from the curve and then adjusted for the known concentration of its test solution.

When the response to the Standard can be plotted linearly against the log-dose, it is fitted numerically by a straight line, as described in the preceding section. For assays in randomized sets, a standard curve is computed with  $b$  for the assay and  $y$  for each set and the response  $y_U$  in each tube of a given Unknown in that set is converted to an estimated log-relative potency,

$$X = (y_U - Y_S)/b \quad (7)$$

where  $Y_S$  is the response predicted by the standard curve at the assumed log-dose  $x$  of the Unknown. The average of the separate estimates from each of  $f$  sets,  $M' = \Sigma X/f$ , is the assayed log-relative potency of the Unknown.

Factorial Assays from the Response to Each Treatment— When some function of the response can be plotted linearly against the log-dose, the assayed potency is computed from the total response for each treatment, and its precision is measured in terms of confidence intervals. This requires that (1) in suitable units the response ( $y$ ) depends linearly upon the log-dose within the dosage range of the assay, and (2) the number ( $f$ ) of responses be the same at each dosage level of both Standard and Unknown. The  $y$ 's are totaled at each dosage level of each preparation. In different combinations, these totals,  $T_t$ , lead directly to the log-relative potency and to tests of assay validity. The factorial coefficients in [Tables 6, 7, and 8](#) determine how they are combined. In a given row, each  $T_t$  is multiplied by the corresponding coefficient and the products summed to obtain  $T_i$ . The  $T_i$ 's in the successive rows carry the same meaning in all assays.

Table 6

Factorial coefficients  $x_1$  for analyzing a balanced bioassay, in which successive log-doses of Standard ( $S_i$ ) and of Unknown ( $U_i$ ) are spaced equally, each with the same number ( $f$ ) of responses totaling  $T_t$ .

$L$		26, 29		$c'$		1		8/3		5	

Ta in the first row measures the difference in the average response to the Standard and to the Unknown. Tb in the second row leads directly to the combined slope of the dosage-response curves for both Standard and Unknown. The third to the fifth rows (ab, q, and aq) provide tests for the validity of an assay, as described in a later section. From the totals Ta and Tb, compute the log-relative potency of the Unknown, before adjustment for its assumed potency, as

$$M' = ciT_a/T_b \quad (8)$$

where  $i$  is the interval in logarithms between successive log-doses of both the Standard and the Unknown, and the constant  $c$  is given separately at the bottom of each table. Each  $M'$  is corrected to its log-potency  $M$  by Equation 2.

When doses are spaced unequally on a log scale, as in [Table 8](#), use instead the constant  $c_i$  at the bottom of the table.

Table 7

Factorial coefficients  $x_1$  for analyzing a partially balanced assay, in which successive log-doses of Standard ( $S_i$ ) and of Unknown ( $U_i$ ) are spaced equally, each with the same number ( $f$ ) of responses totaling  $T_t$ . If the number of successive doses of the Unknown exceeds by one the number on the Standard, interchange  $S_i$  and  $U_i$  in the heading and reverse all signs in rows a, ab, and aq.

In a fully balanced assay, such as the assay for corticotropin, compute  $M'$  with the coefficients in [Table 6](#). If one preparation has one less dose than the other but the successive log-doses of both Standard and Unknown differ by a constant interval  $i$ , use the factorial coefficients in [Table 7](#), correcting for the actual difference between the observed mean log-doses,  $x_S$  and  $x_U$ , by computing

$$M' = \bar{x}_S - \bar{x}_U + M' \quad (9)$$

In assays where the successive doses are not spaced at equal log-intervals, the log-relative potency of a single Unknown may be computed by Equation 8 with the factorial coefficients and  $ci$  in [Table 8](#).

In an assay of two or more Unknowns against a common Standard, all with dosage-response lines that are parallel within the experimental error, each log-relative potency may be computed with the same assay slope as follows. For each preparation, determine the slope factor  $Tb' = \Sigma(x_1 Tt) or \Sigma(x_1 y)$ , where the values of  $x_1$  are the factorial coefficients for the Standard in the appropriate row b of [Table 6](#) or [8](#). The log-relative potency of each Unknown is

$$M' = ci h' T_a / 2 \Sigma T_b' \quad (10)$$

where  $h'$  is the number of values of  $Tb'$  summed in the denominator.

Assays from Differences in Response— When doses of the Standard and Unknown are paired and the difference in response is computed for each pair, these differences are not affected by variations in the average sensitivity of the paired readings. The paired 2-dose insulin assay corresponds to the first design in [Table 6](#), and requires four equal groups of rabbits each injected twice (see [Insulin Assays](#) [121](#)). The difference ( $y$ ) in the blood sugar response of each rabbit to the two treatments leads to the log-relative potency  $M'$  (see the first two paragraphs of the section, Calculation of Potency from a Single Assay). The Vasopressin Injection assay follows a similar design, substituting two or more randomized sets of four successive pairs of injections into rats for the four treatment groups of rabbits in the insulin assay.

Oxytocin Injection is assayed from blood pressure changes in a single test animal following alternating injections of a single dose of Standard and of one of two doses of the Unknown. The calculation of potency from the differences in the response of the Unknown and to the average of the two adjacent responses to the Standard is equivalent to the first design in [Table 7](#) with S and U reversed, where  $i$  is the log-interval between the two dosage levels of the Unknown.

#### Experimental Error and Tests of Assay Validity

As the term is used here, "experimental error" refers to the residual variation in the response of biological indicators, not to a mistake in procedure or to an outlier that needs replacement. It is measured in terms of the error variance of a single response or other unit, which is designated uniformly as  $s^2$ , despite differences in the definition of the unit. It is required in tests of assay validity and in computing the confidence interval.

Error Variance of a Threshold Dose— The individual threshold dose is measured directly in some assays. In a Digitalis assay, designate each individual threshold dose by the symbol  $z$ , the number or frequency of  $z$ 's by  $f$ , and the total of the  $z$ 's for each preparation by  $T$ , with subscripts S and U for Standard and Unknown, respectively. Compute the error variance of  $z$  as

$$s^2 = [\Sigma z^2 - T_S^2/f_S - T_U^2/f_U]/n \quad (11)$$

with  $n = f_S + f_U - 2$  degrees of freedom. In the assay of Tubocurarine Chloride Injection, each log-threshold dose of the Unknown is subtracted from the corresponding log-dose of the Standard in the same rabbit to obtain an individual difference  $x$ . Since each  $x$  may be either positive or negative (+ or -), it is essential to carry the correct sign in all sums. Designate the total of the  $x$ 's for the animals injected with the Standard on the first day as  $T_1$ , and for those injected with the Standard on the second day as  $T_2$ . Compute the error variance of  $x$

with  $n = N - 2$  degrees of freedom as

$$s^2 = \{\Sigma x^2 - (T_1^2 + T_2^2)/f\}/n \quad (12)$$

where  $N$  is the total number of rabbits that complete the assay, excluding any replacement for a missing value to equalize the size of the two groups.

Error Variance of an Individual Response— In the Pharmacopeial assays, differences in dose that modify the mean response are assumed not to affect the variability in the response. The calculation of the error variance depends upon the design of the assay and the form of the adjustment for any missing values. Each response is first converted to the unit  $y$  used in computing the potency. Determine a single error variance from the combined deviations of the  $y$ 's around their respective means for each dosage level, summed over all levels. Doubtful values of  $y$  may be tested as described under Rejection of Outlying or Aberrant Observations, and proved outliers may be replaced as missing values (see Replacement of Missing Values).

In the simplest design, the units of response are assigned at random to each dosage level, as in the assay for corticotropin. If a missing value is replaced by adding the mean of the

Chaining y's at any given dosage level to their total, the degrees of freedom (n) in the error variance are reduced by one for each replacement but no other change is needed in the calculation. Assuming that f is then the same for all doses or groups, compute the error variance from the variation within doses of all the y's as

$$s^2 = \{\sum y^2 - \sum T_i^2/f\}/n \quad (13)$$

where  $T_i$  is the total at each dose of the f values of y, there are k totals  $T_i$  and the degrees of freedom  $n = \sum f - k$ , with  $\sum f$  diminished by 1 for each replacement.

If variations in f are adjusted by subtracting a group mean from its group total, compute the error variance from the observed y's and the unadjusted totals  $T_i$  as

$$s^2 = \{\sum y^2 - \sum (T_i^2/f)\}/n \quad (14)$$

where  $n = \sum f - k$ .

In the calculation of the result of an assay using the coefficients of [Table 6](#) or [8](#),  $s^2$  may be computed from the response y for each of the h' preparations, including the h Unknowns and the corresponding dosage levels of the Standard. For each preparation, compute  $T' = \sum y$  and the slope factor  $Tb' = \sum (x_1 y)$  where the values of  $x_1$  are the factorial coefficients for the Standard in the appropriate row b of [Table 6](#) or [8](#). The error variance for the assay is

$$s^2 = \{\sum y^2 - \sum T'^2/k - 2(\sum T_b')^2/h'e_b f\}/n \quad (15)$$

where the degrees of freedom  $n = h' (k - 1) - 1$ , and  $e_b$  is the ei from the same table and row as the coefficients  $x_1$ .

The Error Variance in Restricted Designs— In some assays, the individual responses occur in randomized sets of three or more. Examples of sets are litter mates in the assay of vitamin D, the cleared areas within each plate in an antibiotic assay, and the responses following four successive pairs of injections in the vasopressin assay. Arrange the individual y's from these assays in a 2-way table, in which each column represents a different treatment or dose and each row a randomized set. Losses may be replaced as described under Replacement of Missing Values. The k column totals are the  $T_i$ 's required for the analysis of balanced designs. The f row totals ( $T_r$ ) represent a source of variation that does not affect the estimated potency and hence is excluded from the assay error. Compute the approximate error variance from the squares of the individual y's and of the marginal totals as

$$s^2 = \{\sum y^2 - \sum T_r^2/k - \sum T_i^2/f + T^2/N\}/n \quad (16)$$

where  $T = \sum T_r = \sum T_i$ , and the  $n = (k - 1)(f - 1)$  degrees of freedom must be diminished by one for any gap in the original table that has been filled by computation.

When the order of treatment is an additional potential source of variation, its effect can be corrected by the dose regimen for a series of n' Latin squares with k rows in common, such as that for the two Latin squares in the dose regimens 1 to 4 and 5 to 8 in the assay of Glucagon for Injection. List the observed responses y of each test animal in a separate column in the order of dosing. The responses to each of the k doses then occur equally often in each of the k rows and of the n' k columns, where n' is the number of Latin squares. Total the responses y in each row ( $T_r$ ) in each column ( $T_c$ ), and, in a separate listing, for each dose or treatment ( $T_i$ ). An occasional lost reading may be replaced by Equation 1a as described under Replacement of Missing Values. Compute the error variance from the squares of the individual y's and of the marginal and treatment totals as

$$s^2 = \{\sum y^2 - \sum T_r^2/n'k - \sum T_c^2/k - \sum T_i^2/n'k + 2T^2/N\}/n \quad (16a)$$

where  $T = \sum y = \sum T_r = \sum T_c = \sum T_i$ ,  $N = n' k^2$ , and the  $n = (k - 1)(n' k - 2)$  degrees of freedom must be diminished by one for any gap in the original table that has been filled by computation.

In assays where the reactions occur in pairs, the differences between test animals or paired reactions are segregated automatically by calculating the assay with the difference within pair as the response. With insulin, the response is the difference y in the blood sugar of a single rabbit following two injections (see [Insulin Assay](#) (121)). After adjustment for rabbits lost during the assay, compute the error variance of y from the responses in all four groups and from the group totals  $T_i = T_1$  to  $T_4$  as

$$s^2 = \{\sum y^2 - \sum T_i^2/f\}/n \quad (17)$$

where the number of rabbits f is the same in each group and the degrees of freedom,  $n = 4(f - 1)$ , are reduced by one for each replacement of a rabbit lost during the assay. In the Oxytocin Injection assay, each y represents the difference between the blood pressure response to a dose of the Unknown and the average for the two adjacent doses of Standard.

Compute the error variance of y as

$$s^2 = \{\sum y^2 - (T_1^2 + T_2^2)/f\}/n \quad (18)$$

with  $n = 2(f - 1)$  degrees of freedom, where  $T_1$  is the total of the y's for the low dose of the Unknown and  $T_2$  for the high dose.

In a microbial assay calculated by interpolation from a standard curve, convert each difference between two paired responses to units of log-dose, X, by the use of Equation 7. With each difference X as the unit, a composite  $s^2$  is computed from the variation in the f values of X for each Unknown, totaled over the h Unknowns in the assay, as

$$s^2 = \{\sum X^2 - \sum (T_x^2/f)\}/n \quad (19)$$

where  $T_x = \sum X$  for a single Unknown and the degrees of freedom  $n = \sum f - h$ .

Tests of Assay Validity— In addition to the specific requirements in each monograph and a combined log-dose response curve with a significant slope (see the statistic C in the next section), two conditions determine the validity of an individual factorial assay: (1) the log-dose response curve for the Unknown must parallel that for the Standard within the experimental error, and (2) neither curve may depart significantly from a straight line. When the assay has been completely randomized or consists of randomized sets, the necessary tests are computed with the factorial coefficients for ab, q, and aq from [Tables 6](#) to [8](#) and the treatment totals  $T_i$ . Sum the products of the coefficients in each row by the corresponding  $T_i$ 's to obtain the product total  $T_i$ , where the subscript i stands in turn for ab, q, and aq, respectively. Each of the three ratios,  $T_i^2/e_i f$ , is computed with the corresponding value of  $e_i$  from the table and with f equal to the number of y's in each  $T_i$ . That in row ab tests whether the dosage-response lines are parallel, and is the only test available in a 2-dose assay. With three or more doses of both preparations, that in row q is a test of combined curvature in the same direction, and in row aq of separate curvatures in opposite directions. If any ratio in a 3- or 4-dose assay exceeds  $s^2$  as much as three-fold, compute

$$F_3 = \sum (T_i^2/e_i f)/3s^2 \quad (20)$$

For a 2-dose assay, compute instead

$$F_1 = T_{ab}^2/e_{ab} fs^2 \quad (21)$$

and for a 3,2 assay ([Table 7](#)) determine

$$F_2 = \Sigma(T_i^2/e_i f)/2s^2 \quad (22)$$

For a valid assay,  $F_1$ ,  $F_2$ , or  $F_3$  does not exceed the value given in [Table 9](#) (at odds of 1 in 20) for the degrees of freedom  $n$  in  $s^2$ .

Table 9

<sup>†</sup> Adapted from portions of Tables III to V of "Statistical Tables for Biological, Agricultural and Medical Research," by R. A. Fisher and F. Yates, published by Oliver and Boyd, Ltd., Edinburgh.

An assay may fail the test for validity and still provide a contributory estimate of potency that can be combined profitably with the result of a second assay of the same Unknown, as described in a later section. An end dosage level for either the Standard or the Unknown, or both, may fall outside the linear zone. With three or more dosage levels and relatively large values of  $T_a$ ,  $T_{ab}$ , and  $T_{aq}$ , the total response  $T_t$  at an end dose of one preparation may approach an upper or lower limit and be responsible for the large values of  $T_{ab}$  and  $T_{aq}$ . This  $T_t$  may be omitted and the assay recomputed with the appropriate design in [Table 7](#). If the assay then meets the test in Equation 20, or 22, the resulting potency,  $M$ , may be combined with that of a second assay in computing the log-potency of the Unknown (see under Combination of Independent Assays). If  $T_a$  is not significant but  $T_q$  shows significant combined curvature, the largest (or smallest) dose of both preparations may be too large (or too small). Their omission may lead to a valid assay with the factorial coefficients for the next smaller design in [Table 6](#) or [8](#). A statistically significant  $T_q$  or  $\Sigma T_q'$  may be neglected and all dosage levels retained without biasing the computed log-potency  $M'$  and its confidence interval by more than 5% when the following inequality is true:

$$\begin{aligned} T_b^2/e_b &> 100T_q^2/e_q \\ \text{or} \\ (\Sigma T_b')^2/e_b &> 100(\Sigma T_q')^2/e_q \end{aligned} \quad (23)$$

where each  $T_b'$  and  $T_q'$  is computed with the  $T_t$ 's (or  $y$ 's) for a single preparation multiplied by the coefficients for the Standard in rows  $b$  and  $q$ , respectively. If both  $T_a$  and  $T_{ab}$  are significant in a 2-dose assay, one  $T_t$  may be outside the linear zone. Sometimes a preliminary or contributory estimate of potency can be computed from the remaining three values of  $T_t$  and the first design in [Table 7](#). In assays of insulin and of other drugs in which the responses are paired, the test for parallelism is so insensitive that it is omitted. If the tubes in each set are arranged systematically instead of at random in a microbial assay, the tests for validity may be subject to bias from positional effects.

#### The Confidence Interval and Limits of Potency

A bioassay provides an estimate of the true potency of an Unknown. This estimate falls within a confidence interval, which is computed so that the odds are not more than 1 in 20 ( $P = 0.05$ ) that the true potency either exceeds the upper limit of the confidence interval or is less than its lower limit. Since this interval is determined by a number of factors that may influence the estimate of potency, the required precision for most bioassays is given in the monograph in terms of the confidence interval, related either to the potency directly or to its logarithm.

General Calculation— Despite their many forms, bioassays fall into two general categories: (1) those where the log-potency is computed directly from a mean or a mean difference, and (2) those where it is computed from the ratio of two statistics.

(1) When the log-potency of an assay is computed as the mean of several estimated log-potencies that are approximately equal in precision, the log-confidence interval is

$$L = 2st/\sqrt{k} \quad (24)$$

where  $s$  is the standard deviation of a single estimated log-potency,  $t$  is read from [Table 9](#) with the  $n$  degrees of freedom in  $s$ , and  $k$  is the number of estimates that have been averaged. The same equation holds where the log-potency is computed as the mean  $x$  of  $k$  differences  $x$ , with  $s$  the standard deviation of a single  $x$ . In either case, the estimated log-potency  $M$  is in the center of its confidence interval, so that its confidence limits are

$$X_M = M + \frac{1}{2}L \text{ and } M - \frac{1}{2}L, \text{ or } X_M = M \pm \frac{1}{2}L \quad (25)$$

The upper and lower limits are converted to their antilogarithms to obtain the limits as explicit potencies.

(2) More often, the log-potency or potency is computed from a ratio, and in these cases the length of the confidence interval is typified by the log-interval in the equation

$$L = 2\sqrt{(C-1)(CM'^2 + c'i^2)} \quad (26)$$

where  $M'$  is the log-relative potency as defined (see Calculation of Potency from a Single Assay),  $i$  is the log-interval between successive doses, and  $c'$  is a constant characteristic of

... assay procedure. The remaining term C depends upon the precision with which the slope of the dosage-response curve has been determined. (This is sometimes expressed ... terms of  $g = (C - 1)/C$ .) In factorial assays, it is computed as

$$C = T_b^2 / (T_b^2 - e_b f s^2 t^2) \quad (27)$$

where  $s^2$  is the error variance of a single observation,  $t^2$  is read from [Table 9](#) with the degrees of freedom in  $s^2$ ,  $f$  is the number of responses in each  $T_t$  used in calculating  $T_b$ , and  $T_b$  and  $e_b$  are computed with the factorial coefficients for row b in [Tables 6 to 8](#). The  $s^2$  in Equation 26 depends upon the design of the assay, as indicated for each drug in the next section. In a valid assay, C is a positive number.

In an assay of two or more Unknowns against a common Standard, all with dosage-response curves that are parallel within the experimental error, C may be computed with the error variance  $s^2$  for the assay and with the assay slope as

$$C = (\Sigma T_b')^2 / \{(\Sigma T_b')^2 - e_b f h' s^2 t^2 / 2\} \quad (28)$$

The slope factor  $T_b' = \Sigma(x_1 T_t)$  or  $\Sigma(x_1 y)$  for each of the  $h'$  preparations, including the Standard, is computed with the factorial coefficients  $x_1$  for the Standard in the appropriate row b of [Table 6](#) or [8](#). If a treatment total  $T_t$  includes one or more replacements for a missing response, replace  $e_b f$  in Equation 27, or  $e_b f h'/2$  in Equation 28, by  $f^2 \Sigma(x_1 t^2)$ , where each  $x_1$  is a factorial coefficient in row b of [Tables 6 to 8](#), in this chapter, and  $f'$  is the number of responses in the corresponding  $T_t$  before adding the replacement. With this C, compute the confidence interval as

$$L = 2\sqrt{(C - 1)(CM^2 + c' t^2 h' / 2)} \quad (29)$$

In assays computed from a ratio, the most probable log-potency M is not in the exact center of the confidence interval. The upper and lower confidence limits in logarithms are

$$X_M = \log R + CM' + \frac{1}{2}L \text{ and } \log R + CM' - \frac{1}{2}L \quad (30)$$

C is often very little larger than unity, and the more precise the assay, the more nearly C approaches 1 exactly.  $R = z_S / z_U$  is the ratio of corresponding doses of the Standard and of the Unknown or the assumed potency of the Unknown. The upper and lower confidence limits in log-potencies are converted separately to their antilogarithms to obtain the corresponding potencies.

Confidence Intervals for Individual Assays— Since the confidence interval may vary in detail from the above general patterns, compute it for each assay by the special directions given under the name of the substance in the paragraphs following.

Antibiotic Assays— The confidence interval may be computed by Equations 24 and 25.

Calcium Pantothenate— For log-potencies obtained by interpolation from the Standard curve, the confidence interval may be computed with Equations 19 and 24. For log-potencies calculated with Equation 8 or 10,  $s^2$  may be computed with Equation 15, C with Equation 27 or 28, and the confidence interval L with Equation 26 or 29.

Corticotropin Injection— Compute the log confidence interval by Equations 26 and 27, with the coefficients and constants in [Table 6](#) for a 3-dose assay, and  $s^2$  as determined by Equation 13 or 14.

Digitalis— Compute the confidence interval as

$$L = 2\sqrt{(C - 1)\{C(\bar{z}_S/\bar{z}_U)^2 + f_U/f_S\}} \quad (31)$$

where  $f_U$  and  $f_S$  are the number of observations on the Unknown and on the Standard, and

$$C = \bar{z}_U^2 / (\bar{z}_U^2 - s^2 t^2 / f_U) \quad (32)$$

is determined with  $s^2$  from Equation 11. The confidence limits for the potency in USP Units are then

$$X_{P_*} = R\{C(\bar{z}_S/\bar{z}_U) \pm \frac{1}{2}L\} \quad (33)$$

in which R is as defined in the Glossary of Symbols.

Glucagon for Injection— Compute the error variance  $s^2$  by Equation 15a, C by Equation 27 with  $e_b f = 16n'$ , and the log confidence interval L by Equation 26 with  $c' i^2 = 0.09062$ .

Chorionic Gonadotropin— Proceed as directed under Corticotropin Injection.

Heparin Sodium— If two independent determinations of the log-potency M differ by more than 0.05, carry out additional assays and compute the error variance among the N values of M as

$$s^2 = \{\Sigma M^2 - (\Sigma M)^2 / N\} / n \quad (34)$$

with  $n = N - 1$  degrees of freedom. Given this value, determine the confidence interval in logarithms (L) by Equation 24.

Insulin Injection— Compute the error variance ( $s^2$ ) of y by Equation 16 and C as

$$C = T_b^2 / (T_b^2 - s^2 t^2 N) \quad (35)$$

where  $t^2$  from [Table 9](#) depends upon  $n = 4(f - 1)$  degrees of freedom in  $s^2$  and  $N = 4f$  is the total number of differences in the four groups. By Equation 26, compute the confidence interval L in logarithms, where  $c' i^2 = 0.09062$ . The upper and lower confidence limits in USP Units of insulin are given by the antilogarithms of  $X_M$  from Equation 30.

Oxytocin Injection— Compute the approximate log confidence interval by Equation 26, in which

$$C = (T_2 - T_1)^2 / \{(T_2 - T_1)^2 - 4(f + 1)s^2 t^2 / 3\} \quad (36)$$

where  $s^2$  is defined by Equation 18, and

$$c' = (4f - 1) / 8(f + 1) \quad (37)$$

Tubocurarine Chloride Injection— Compute the error variance by Equation 12, and the confidence interval by Equation 24.

Vasopressin Injection— Compute the error variance  $s^2$  by Equation 16, C by Equation 35, and the log confidence interval by Equation 26, where  $c' = 1$  and  $i$  is the log-interval separating the two dosage levels.

Vitamin B12 Activity— Proceed as directed under Calcium Pantothenate.

#### Combination of Independent Assays

When the method permits, additional animals can be added to an insufficiently precise assay until the combined results reduce the confidence interval within the limits specified in the monograph. Where two or more independent assays are required, each leading to a log-potency M, the M's are combined in determining the weighted mean potency of the Unknown. Except in the Heparin Sodium assay, where the log-potencies are weighted equally, the relative precisions of the two or more independent M's determine the weight assigned to each value in computing their mean and its confidence interval.

Before combining two or more separate estimates of M, test their mutual consistency. If the M's are consistent, their respective confidence intervals will overlap. Where the intervals do not overlap or where the overlap is small, compute an approximate  $\chi^2_M$ . Assign each of the  $h$  individual assays a weight w, defined as

$$w = 4t^2/L^2 \quad (38)$$

where the length of the confidence interval L is computed with the appropriate equation from the preceding section, and  $t^2$  is read from [Table 9](#) for the degrees of freedom n in the error variance of the assay. Sum the individual weights to obtain  $\Sigma w$ . Then an approximate  $\chi^2$  with  $h - 1$  degrees of freedom is determined as

$$\text{Approx. } \chi^2_M = \Sigma(wM^2) - \{\Sigma(wM)\}^2/\Sigma w \quad (39)$$

For two assays with log-potencies M1 and M2 and weights w1 and w2, Equation 35 reduces to

$$\text{Approx. } \chi^2_M = \frac{w_1 w_2 (M_1 - M_2)^2}{w_1 + w_2} \quad (40)$$

with one degree of freedom. If the approximate  $\chi^2_M$  is well under the critical value for  $\chi^2$  in [Table 9](#), use the weights w in computing the mean log-potency M and its confidence interval, L. If  $\chi^2_M$  approaches or exceeds this critical value, use instead the semi-weights w' (Equation 47) when computing M.

Compute the mean log-potency M of two or more mutually consistent assays as

$$\bar{M} = \Sigma(wM)/\Sigma w \quad (41)$$

This is the most probable single value within a combined confidence interval of length Lc, defined as the square root of

$$L_c^2 = \frac{4t_L^2}{\Sigma w} \left\{ 1 + \frac{4}{\Sigma w^2} \sum \frac{w(\Sigma w - w)}{n'} \right\} \quad (42)$$

where each  $n' = n - 4(h - 2)/(h - 1)$  and  $t_L^2$  is interpolated from [Table 9](#) with the degrees of freedom

$$n_L = \Sigma^2 w / \Sigma(w^2/n) \quad (43)$$

For two assays ( $h = 2$ ) with log-potencies M1 and M2 and weights w1 and w2, respectively, the above equation may be rewritten as

$$L_c^2 = \frac{4t_L^2}{\Sigma w} \left\{ 1 + \frac{4w_1 w_2}{\Sigma w^2} \left[ \frac{1}{n_1} + \frac{1}{n_2} \right] \right\} \quad (43)$$

where  $\Sigma w = w_1 + w_2$ . Where Lc, the confidence interval for a combined estimate, does not exceed the requirement in a monograph, upper and lower confidence limits are taken  $\pm L_c$  above and below M, to obtain approximately a 95% confidence interval.

Where the variation in the assayed potency between the  $h$  independent determinations, as tested by  $\chi^2_M$ , approaches or exceeds  $P = 0.05$ , the several estimates are assigned semi-weights w'. From the weight w, compute the variance of each M as

$$V = 1/w = L^2/4t^2 \quad (44)$$

Calculate the variance of the heterogeneity between assays as

$$v = \frac{\Sigma M^2 - (\Sigma M)^2/h}{h - 1} - \frac{\Sigma V}{h} \quad (45)$$

or if  $h = 2$ ,

$$v = \frac{(M_1 - M_2)^2}{2} - \frac{V_1 + V_2}{2} \quad (46)$$

Where V varies so markedly that v calculated as above is a negative number, compute instead an approximate v by omitting the term following the minus sign in Equations 45 and 46. A semi-weight is defined as

$$w' = 1/(V + v) \quad (47)$$

Substitute w' and  $\Sigma w'$  for w and  $\Sigma w$  in Equation 41 to obtain the semi-weighted mean M. This falls near the middle of a confidence interval of approximate length Lc', where

$$L_c'^2 = 4t^2/\Sigma w' \quad (48)$$

and  $t^2$  from [Table 9](#) has  $\Sigma n$  degrees of freedom.

Where  $\chi^2_M$  in Equation 39, from  $h = 4$  or more estimates of M, exceeds the critical level in [Table 9](#) by more than 50%, and the weights w differ by less than 30%, the h estimates of M may be checked for a suspected outlier with [Table 1](#). Where significant, the outlying M may be omitted in computing M with w'.

Where the potency of a drug is determined repeatedly in a given laboratory by the same bioassay method, successive determinations of both the slope b and the error variance  $s^2$  may

Scatter randomly within the sampling error about a common value for each parameter. Plotting estimates from successive assays on a quality control chart for each statistic and computing the midvalue and control limits defining the allowable random variation make it possible to check continuously the consistency of an assay technique. Where estimates of  $b$  and  $s^2$  from a single assay fall within the control limits, they may be replaced by their laboratory means. Reject any assay in which these statistics fall outside the control limits, or accept it only after close scrutiny with respect to its validity.

#### Joint Assay of Several Preparations

Each monograph describes the assay of a single Unknown against the Standard. Although not provided explicitly, several different Unknowns are often included in the same assay and each is compared separately with the same responses to the Standard. This fact may warrant increasing the number of observations with the Standard. Given  $f$  observations at each dosage level of each of  $h$  different Unknowns, the number of observations at each dosage level of the Standard may be increased advantageously, if  $h$  is large, to

$$f\sqrt{h}.$$

This rule can be applied only approximately where litter differences or their equivalent must be segregated, and in any case is merely suggestive.

If all of several assays conducted concurrently meet the requirements for validity, and have linear log-dose response curves with the same slope  $b$  and the same error variance  $s^2$  about these lines, these two statistics may be considered as characteristic of the assay. Combining all of the evidence from the same assay into a single value of the assay slope results in a more stable and reliable estimate of  $b$  than if each Unknown were analyzed independently. The degrees of freedom and reliability of the error variance  $s^2$  can be increased similarly. Confidence intervals computed with these composite values for  $b$  and  $s^2$  are smaller on the average than if based upon only part of the relevant data. For the calculation or application of such assay estimates, see Equations 10, 15, 16, 19, 28, and 29. The potency estimated with a slope computed from a single Unknown and the Standard agrees within a fraction of the confidence interval with that computed from the combined slope for the entire assay. Since it is based upon more evidence, the latter is considered the better estimate.

#### GLOSSARY

##### Glossary of Symbols

A	absorbance for computing % reduction in bacterial growth from turbidimetric readings.
b	slope of the straight line relating response (y) to log-dose (x) [Equations 2b, 4, 5, 6].
c	constant for computing $M'$ with Equations 8 and 10.
$c'$	constant for computing $L$ with Equations 26 and 29.
$c_i$	constant for computing $M'$ when doses are spaced as in <a href="#">Table 8</a> .
$c'_{i2}$	constant for computing $L$ when doses are spaced as in <a href="#">Table 8</a> .
C	term measuring precision of the slope in a confidence interval [Equations 27, 28, 35, 36].
$\chi_2$	statistical constant for testing significance of a discrepancy [ <a href="#">Table 9</a> ].
$\chi_{M2}$	$\chi_2$ testing the disagreement between different estimates of log-potency [Equations 39, 40].
$eb$	$ei$ from row $b$ in <a href="#">Tables 6 to 8</a> .
$eb' i$	multiple of $\sum(x - \bar{x})^2$ [Table 5; Equation 6].
$ei$	sum of squares of the factorial coefficients in each row of <a href="#">Tables 6 to 8</a> .
$eq$	$ei$ from row $q$ in <a href="#">Tables 6 to 8</a> .
f	number of responses at each dosage level of a preparation; number of replicates or sets.
$f_S$	number of observations on the Standard.
$f_U$	number of observations on the Unknown.
$F1$ to $F3$	observed variance ratio with 1 to 3 degrees of freedom in numerator [ <a href="#">Table 9</a> ].
$G1$ , $G2$ , and $G3$	relative gap in test for outlier [ <a href="#">Table 1</a> ].
h	number of Unknowns in a multiple assay.
$h'$	number of preparations in a multiple assay, including the Standard and $h$ Unknowns; i.e., $h' = h + 1$ .
i	interval in logarithms between successive log-doses, the same for both Standard and Unknown.
k	number of estimated log-potencies in an average [Equation 24]; number of treatments or doses [ <a href="#">Table 4</a> ; Equations 1, 13, 15, 16]; number of ranges or groups in a series [ <a href="#">Table 2</a> ]; number of rows, columns, and doses in a single Latin square [Equations 1a, 16a].
L	length of the confidence interval in logarithms [Equations 24, 26, 29, 38], or in terms of a proportion of the relative potency of the dilutions compared [Equations 31, 33].
$L_c$	length of a combined confidence interval [Equations 42, 43].
$L_c'$	length of confidence interval for a semi-weighted mean $M$ [Equation 48].
LD50	lethal dose killing an expected 50% of the animals under test [Equation 2c].
M	log-potency [Equation 2].
$M'$	log-potency of an Unknown, relative to its assumed potency.
M	mean log-potency.
n	degrees of freedom in an estimated variance $s^2$ or in the statistic $t$ or $\chi_2$ .
$n'$	number of Latin squares with rows in common [Equations 1a, 16a].
N	number; e.g., of observations in a gap test [ <a href="#">Table 1</a> ], or of responses $y$ in an assay [Equation 16].
P	probability of observing a given result, or of the tabular value of a statistic, usually $P = 0.05$ or $0.95$ for confidence intervals [ <a href="#">Tables 1, 2, 9</a> ].

	potency, $P^*$ = antilog M or computed directly.
R	ratio of a given dose of the Standard to the corresponding dose of the Unknown, or assumed potency of the Unknown [Equations 2, 30, 33].
$R^*$	ratio of largest of k ranges in a series to their sum [Table 2].
$s = \sqrt{s_2}$	standard deviation of a response unit, also of a single estimated log-potency in a direct assay [Equation 24].
$s_2$	error variance of a response unit.
Si	a log-dose of Standard [Tables 6, 7].
$\Sigma$	"the sum of."
t	Student's t for n degrees of freedom and probability P = 0.05 [Table 9].
T	total of the responses y in an assay [Equation 16].
$T'$	incomplete total for an assay in randomized sets with one missing observation [Equation 1].
T1	$\Sigma(y)$ for the animals injected with the Standard on the first day [Equations 18, 36].
T2	$\Sigma(y)$ for the animals injected with the Standard on the second day [Equations 18, 36].
Ta	Ti for the difference in the responses to the Standard and to the Unknown [Tables 6 to 8].
Tab	Ti for testing the difference in slope between Standard and Unknown [Tables 6 to 8].
Taq	Ti for testing opposed curvature in the curves for Standard and Unknown [Tables 6 to 8].
Tb	Ti for the combined slope of the dosage-response curves for Standard and Unknown [Tables 6 to 8].
Tb'	$\Sigma(x_1 T_t)$ or $\Sigma(x_1 y)$ for computing the slope of the log-dose response curve [Equations 10, 23, 28].
Ti	sum of products of Tt multiplied by the corresponding factorial coefficients in each row of [Tables 6 to 8].
Tq	Ti for testing similar curvature in the curves for Standard and Unknown [Tables 6 to 8].
Tr	row or set total in an assay in randomized sets [Equation 16].
$Tr'$	incomplete total for the randomized set with a missing observation in Equation 1.
Tt	total of f responses y for a given dose of a preparation [Tables 6 to 8]; Equations 6, 13, 14, 16].
$Tt'$	incomplete total for the treatment with a missing observation in Equation 1.
Ui	a log-dose of Unknown [Tables 6 to 8].
v	variance for heterogeneity between assays [Equation 45].
$V = 1/w$	variance of an individual M [Equations 44 to 47].
w	weight assigned to the M for an individual assay [Equation 38], or to a probit for computing an LD50 [Equations 2a, 2b].
$w'$	semi-weight of each M in a series of assays [Equations 47, 48].
x	a log-dose of drug in a bioassay [Equation 5]; also the difference between two log-threshold doses in the same animal [Equation 12].
$x^*$	coefficients for computing the lowest and highest expected responses YL and YH in a log-dose response curve [Table 4; Equation 3].
x1	a factorial coefficient that is a multiple of $(x - x)$ for computing the slope of a straight line [Table 5; Equation 6].
x	mean log-dose [Equation 5].
xS	mean log-dose for Standard [Equation 9].
xU	mean log-dose for Unknown [Equation 9].
X	log-potency from a unit response, as interpolated from a standard curve [Equations 7a, 7b, 19].
XM	confidence limits for an estimated log-potency M [Equations 25, 30].
XP*	confidence limits for a directly estimated potency $P^*$ (see Digitalis assay) [Equation 33].
y	an observed individual response to a dose of drug in the units used in computing potency and the error variance [Equations 13 to 16]; a unit difference between paired responses in 2-dose assays [Equations 17, 18].
$y_1 \dots y_N$	observed responses listed in order of magnitude, for computing G1, G2, or G3 in Table 1.
y'	replacement for a missing value [Equation 1].
y	mean response in a set or assay [Equation 5].
yt	mean response to a given treatment [Equations 3, 6].
Y	a response predicted from a dosage-response relationship, often with qualifying subscripts [Equations 3 to 5].
z	threshold dose determined directly by titration (see Digitalis assay) [Equation 11].
z	mean threshold dose in a set (see Digitalis assay) [Equations 31, 32, 33].

### 115 DEXPANTHENOL ASSAY

The following procedure is provided for the determination of dexamphenol as an ingredient of multiple-vitamin preparations. It is applicable also to the determination of the dextrorotatory component of racemic panthenol and of other mixtures containing dextrorotatory panthenol.

Media may be prepared as described hereinafter, or dehydrated mixtures yielding similar formulations may be used provided that, when reconstituted as directed by the manufacturer or distributor, they have growth-promoting properties equal to or superior to those obtained from the formulas given herein.

USP Reference Standards (11) — [USP Dexamphenol RS](#).

Standard Stock Solution of Dexamphenol— Dissolve an accurately weighed quantity of [USP Dexamphenol RS](#) in water, dilute with water to obtain a solution having a known concentration of about 800  $\mu$ g per mL, and mix. Store in a refrigerator, protected from light, and use within 30 days.

Standard Preparation— On the day of the assay, prepare a water dilution of the Standard Stock Solution of Dexamphenol to contain 1.2  $\mu$ g of dexamphenol per mL.

Assay Preparation— Proceed as directed in the individual monograph for preparing a solution expected to contain approximately the equivalent of the dexamphenol concentration in the Standard Preparation.

Modified Pantothenate Medium—

Acid-Hydrolyzed Casein Solution	25 mL
Cystine-Tryptophane Solution	25 mL
Polysorbate 80 Solution	0.25 mL
Dextrose, Anhydrous	10 g
Sodium Acetate, Anhydrous	5 g
Adenine-Guanine-Uracil Solution	5 mL
Riboflavin-Thiamine Hydrochloride-Biotin Solution	5 mL
Para-aminobenzoic Acid-Niacin-Pyridoxine Hydrochloride Solution	5 mL
Salt Solution A	5 mL
Salt Solution B	5 mL
Pyridoxal-Calcium Pantothenate Solution	5 mL
Polysorbate 40-Oleic Acid Solution	5 mL

Dissolve the anhydrous dextrose and sodium acetate in the solutions previously mixed, and adjust with 1 N sodium hydroxide to a pH of 6.8. Finally, dilute with water to 250 mL, and mix.

Double-Strength Modified Pantothenate Medium— Prepare as directed under Modified Pantothenate Medium, but make the final dilution to 125 mL instead of 250 mL. Prepare fresh.

Acid-Hydrolyzed Casein Solution— Mix 100 g of vitamin-free casein with 500 mL of 6 N hydrochloric acid, and reflux the mixture for 8 to 12 hours. Remove the hydrochloric acid from the mixture by distillation under reduced pressure until a thick paste remains. Redissolve the resulting paste in about 500 mL of water, adjust the solution with 1 N sodium hydroxide to a pH of  $3.5 \pm 0.1$ , and add water to make 1000 mL. Add 20 g of activated charcoal, stir for 1 hour, and filter. Repeat the treatment with activated charcoal. Store under toluene in a refrigerator at a temperature not below  $10^{\circ}$ . Filter the solution if a precipitate forms during storage.

Cystine-Tryptophane Solution— Suspend 4.0 g of L-cystine and 1.0 g of L-tryptophane (or 2.0 g of D,L-tryptophane) in 700 mL to 800 mL of water, heat to  $75 \pm 5^{\circ}$ , and add dilute hydrochloric acid (1 in 2) dropwise, with stirring, until the solids are dissolved. Cool, add water to make 1000 mL, and mix. Store under toluene in a refrigerator at a temperature not below  $10^{\circ}$ .

Adenine-Guanine-Uracil Solution— Dissolve 200 mg each of adenine sulfate, guanine hydrochloride, and uracil, with the aid of heat, in 10 mL of 4 N hydrochloric acid, cool, add water to make 200 mL, and mix. Store under toluene in a refrigerator.

Polysorbate 80 Solution— Dissolve 25 g of polysorbate 80 in alcohol to make 250 mL, and mix.

Riboflavin-Thiamine Hydrochloride-Biotin Solution— Prepare a solution containing, in each mL, 20  $\mu$ g of riboflavin, 10  $\mu$ g of thiamine hydrochloride, and 0.04  $\mu$ g of biotin, by dissolving riboflavin, thiamine hydrochloride, and biotin in 0.02 N acetic acid. Store, protected from light, under toluene in a refrigerator.

Para-aminobenzoic Acid-Niacin-Pyridoxine Hydrochloride Solution— Prepare a solution in neutral 25 percent alcohol to contain 10  $\mu$ g of para-aminobenzoic acid, 50  $\mu$ g of niacin, and 40  $\mu$ g of pyridoxine hydrochloride in each mL. Store in a refrigerator.

Salt Solution A— Dissolve 25 g of monobasic potassium phosphate and 25 g of dibasic potassium phosphate in water to make 500 mL. Add 5 drops of hydrochloric acid, mix, and store under toluene.

Salt Solution B— Dissolve 10 g of magnesium sulfate, 0.5 g of sodium chloride, 0.5 g of ferrous sulfate, and 0.5 g of manganese sulfate in water to make 500 mL. Add 5 drops of hydrochloric acid, mix, and store under toluene.

Pyridoxal-Calcium Pantothenate Solution— Dissolve 40 mg of pyridoxal hydrochloride and 375  $\mu$ g of calcium pantothenate in 10 percent alcohol to make 2000 mL, and mix. Store in a refrigerator, and use within 30 days.

Polysorbate 40-Oleic Acid Solution— Dissolve 25 g of polysorbate 40 and 0.25 g of oleic acid in 20 percent alcohol to make 500 mL, and mix. Store in a refrigerator, and use within 30 days.

Stock Culture of *Pediococcus acidilactici*— Dissolve in about 800 mL of water, with the aid of heat, 6.0 g of peptone, 4.0 g of pancreatic digest of casein, 3.0 g of yeast extract, 1.5 g of beef extract, 1.0 g of dextrose, and 15.0 g of agar. Adjust with 0.1 N sodium hydroxide or 0.1 N hydrochloric acid to a pH between 6.5 and 6.6, adjust the volume with water to 1000 mL, and mix. Add approximately 10-mL portions of the solution to culture tubes, place caps on the tubes, and sterilize at  $121^{\circ}$  for 15 minutes. Cool on a slant, and store in a refrigerator. Prepare a stock culture of *Pediococcus acidilactici* on a slant of this medium. Incubate at  $35^{\circ}$  for 20 to 24 hours, and store in a refrigerator. Maintain the stock culture by monthly transfer onto fresh slants.

Inoculum— Inoculate three 250-mL portions of Modified Pantothenate Medium from a stock culture slant, and incubate at  $35^{\circ}$  for 20 to 24 hours. Centrifuge the suspension from the combined portions, and wash the cells with Modified Pantothenate Medium. Resuspend the cells in sufficient Modified Pantothenate Medium so that a 1:50 dilution, when tested in a 13-mm diameter test tube, gives 80% light transmission at 530 nm. Transfer 1.2-mL portions of this stock suspension to glass ampuls, seal, freeze in liquid nitrogen, and store in a freezer. On the day of the assay, allow the ampuls to reach room temperature, mix the contents, and dilute 1 mL of thawed culture with sterile saline TS to 150 mL. [note—This dilution may be altered, when necessary, to obtain the desired test response.]

Procedure— Prepare in triplicate a series of eight culture tubes by adding the following quantities of water to the tubes within a set: 5.0 mL, 4.5 mL, 4.0 mL, 3.5 mL, 3.0 mL, 2.0 mL, 1.0 mL, and 0.0 mL. To these same tubes, and in the same order, add 0.0 mL, 0.5 mL, 1.0 mL, 1.5 mL, 2.0 mL, 3.0 mL, 4.0 mL, and 5.0 mL of the Standard Preparation.

Prepare in duplicate a series of five culture tubes by adding the following quantities of water to the tubes within a set: 4.0 mL, 3.5 mL, 3.0 mL, 2.0 mL, and 1.0 mL. To these same tubes, and in the same order, add 1.0 mL, 1.5 mL, 2.0 mL, 3.0 mL, and 4.0 mL of the Assay Preparation.

Add 5.0 mL of Double-Strength Modified Pantothenate Medium to each tube, and mix. Cover the tubes with metal caps, and sterilize in an autoclave at  $121^{\circ}$  for 5 minutes. Cool to room temperature in a chilled water bath, and inoculate each tube with 0.5 mL of the Inoculum. Allow to incubate at  $37^{\circ}$  for 16 hours. Terminate growth by heating to a temperature not

below 80°, such as by steaming at atmospheric pressure in a suitable sterilizer, for 5 to 10 minutes. Cool, and concomitantly determine the percentage transmittance of the suspensions, in cells of equal pathlength, on a suitable spectrophotometer, at 530 nm.

**Calculation**— Draw a dose-response curve on arithmetic graph paper by plotting the average response, in percent transmittance, for each set of tubes of the standard curve against the standard level concentrations. The curve is drawn by connecting each adjacent pair of points with a straight line. From this standard curve, determine by interpolation the potency, in terms of dexpanthenol, of each tube containing portions of the Assay Preparation. Divide the potency of each tube by the amount of Assay Preparation added to it, to obtain the individual responses. Calculate the mean response by averaging the individual responses that vary from their mean by not more than 15%, using not less than half the total number of tubes. Calculate the potency of the portion of the material taken for assay, in terms of dexpanthenol, by multiplying the mean response by the appropriate dilution factor.

\* American Type Culture Collection No. 8042 is suitable.

## 121 INSULIN ASSAYS

The most prominent manifestation of insulin activity, an abrupt decrease in blood glucose, was the basis for biologic assay from the time of its first clinical use. The procedure, although relatively cumbersome, has the great merit of accurately reflecting the effect on the diabetic patient. The advent of practical yet sophisticated physicochemical methods (e.g., liquid chromatography) to measure insulin potency quantitatively has resulted in a more accurate and precise compendial test for insulin and insulin products. However, the bioidentity of insulin and insulin products cannot be assessed by these methods. Thus, a qualitative test in rabbits is included in this chapter, and its use is called for in the appropriate monographs.

**The Rabbit Blood Sugar Method**—Quantitative is used to determine the potency of Insulin Reference Standards, for the validation of the stability of new insulin preparations, and to determine the specific activities of insulin analogs.

### RABBIT BLOOD SUGAR METHOD—QUANTITATIVE

USP Reference Standards (11)—[USP Dextrose RS](#), [USP Insulin RS](#), [USP Insulin \(Beef\) RS](#), [USP Insulin Human RS](#), [USP Insulin \(Pork\) RS](#).

**Diluent**— Prepare an aqueous solution containing 0.1% to 0.25% (w/v) of either cresol or phenol, 1.4% to 1.8% (w/v) of glycerin, and sufficient hydrochloric acid to produce a pH between 2.5 and 3.5, unless otherwise directed in the individual monograph.

**Standard Stock Solution**— Dissolve either a suitable quantity of accurately weighed [USP Insulin RS](#) or a vial of lyophilized [USP Insulin RS](#) of the appropriate species in Diluent to make a Standard Stock Solution containing 40 USP Insulin Units per mL and having a pH between 2.5 and 3.5, unless otherwise directed in the individual monograph. Store in a cold place, protected from freezing, and use within 6 months.

**Standard Solutions**— Dilute portions of the Standard Stock Solution with Diluent to make two solutions, one to contain 1.0 USP Insulin Unit per mL (Standard Solution 1), and the other to contain 2.0 USP Insulin Units per mL (Standard Solution 2).

**Assay Stock Solution**— Proceed as directed under Standard Stock Solution, except to use a suitable quantity of the preparation under test in place of [USP Insulin RS](#). The Assay Stock Solution contains about 40 USP Insulin Units per mL.

**Assay Solutions**— Dilute portions of the Assay Stock Solution with Diluent to make two dilutions of the preparation under test, one of which may be expected, on the basis of the assumed potency, to contain 1.0 USP Insulin Unit per mL (Assay Solution 1), and the other to contain 2.0 USP Insulin Units per mL (Assay Solution 2). In the case of neutral insulin injection, adjust to a pH of 2.5 to 3.5 prior to making the dilutions.

**Doses of the Solutions To Be Injected**— Select on the basis of trial or experience the dose of the dilutions to be injected, the volume of which usually will be between 0.30 mL and 0.50 mL. For each animal the volume of the Standard Solution is the same as that of the Assay Solution.

**Preparation of Animal**— Select suitable, healthy rabbits each weighing not less than 1.8 kg. Keep the rabbits in the laboratory for not less than 1 week before use in the assay, maintaining them on an adequate uniform diet, with water available at all times.

**Procedure**— Divide the rabbits into four equal groups of preferably not less than six rabbits each. On the preceding day, approximately 20 hours before the assay, provide each rabbit with an amount of food that will be consumed within 6 hours. Follow the same feeding schedule before each test day. During the assay, withhold all food until after the final blood specimen is taken. Handle the rabbits with care in order to avoid undue excitement, and inject subcutaneously the doses indicated in the following design (see [Table 1](#)), the second injection being made on the day after the first injection, or not more than 1 week later. The time between the first and second injection is the same for all rabbits.

Table 1

Group	First Injection	Second Injection
1	Standard Solution 2	Assay Solution 1
2	Standard Solution 1	Assay Solution 2
3	Assay Solution 2	Standard Solution 1
4	Assay Solution 1	Standard Solution 2

**Blood Samples**— At 1 hour ± 5 minutes and 2½ hours ± 5 minutes after the time of injection, obtain from each rabbit a suitable blood specimen from a marginal ear vein. Blood can also be collected effectively from the central auricular artery.

**Dextrose Determination**— Determine the dextrose content of the blood specimens by a suitable procedure that is adapted to automated analysis. The following procedure may be used.

**Anticoagulant Solution**— Dissolve 1 g of edetate sodium and 200 mg of sodium fluoride in 1 L of water, and mix.

**Dextrose Standard Preparations**— Transfer known concentrations of [USP Dextrose RS](#) to suitable vessels, and dilute quantitatively and stepwise with Anticoagulant Solution (1:9) to obtain a range of Dextrose Standard Preparations containing between 20 and 100 mg per 100 mL, having known concentrations similar to the concentrations in the rabbit blood samples.

**Test Preparations**— Pipet into separate, suitable vessels 0.1 mL of each Blood Sample and 0.9 mL of Anticoagulant Solution.

**Procedure**— Subject the Test Preparations to dialysis across a semipermeable membrane for a sufficient time so that the dextrose passes through the membrane into a saline TS solution containing glucose oxidase, horseradish peroxidase, 3-methyl-2-benzothiazolinone hydrazone hydrochloride TS, and N,N-dimethylaniline. The absorbances of the Test

Preparations are determined at 600 nm in a recording colorimeter. The absorbances of the Dextrose Standard Preparations are similarly determined at the start and the end of each run.

Calculation— Calculate the response of each rabbit to each injection from the sum of the two blood-sugar values, and subtract its response, disregarding the chronological order in which the responses were observed, to obtain the individual differences,  $y$ , as shown in [Table 2](#).

When the data for one or more rabbits are missing in an assay, do not use the confidence interval formulas given here, but seek statistical help. The data can still be analyzed with proper analysis of variance.

When the number of rabbits,  $f$ , carried through the assay is the same in each group, total the  $y$ 's in each group and compute  $T_a = -T_1 + T_2 + T_3 - T_4$  and  $T_b = T_1 + T_2 + T_3 + T_4$ . The logarithm of the relative potency of the test dilutions is  $M' = 0.301T_a / T_b$ . The potency of the injection in USP Units per mg equals the antilog ( $\log R + M'$ ), where  $R = vS / vU$ , in which  $vS$  is the number of USP Units per mL of the Standard solution and  $vU$  is the number of mg of insulin per mL of the corresponding Assay solution.

Determine the 95% confidence interval for the log-relative potency using Fieller's Theorem (see Appendix and [Design and Analysis of Biological Assays](#) (111)). If the confidence interval is more than 0.082, which corresponds at  $P = 0.95$  to confidence limits of about  $\pm 10\%$  of the computed potency, repeat the assay until the combined data of the two or more assays, redetermined as described in Combination of Independent Assays under [Design and Analysis of Biological Assays](#) (111), meet this acceptable limit.

Table 2

Group	Differences	Individual Response ( $y$ )	Total Response ( $T$ )	Standard Deviations of Differences ( $S$ )
1	Standard Solution 2 – Assay Solution 1	$y_1$	$T_1$	$S_1$
2	Assay Solution 2 – Standard Solution 1	$y_2$	$T_2$	$S_2$
3	Assay Solution 2 – Standard Solution 1	$y_3$	$T_3$	$S_3$
4	Standard Solution 2 – Assay Solution 1	$y_4$	$T_4$	$S_4$

## BIOIDENTITY TEST

Proceed as directed for Rabbit Blood Sugar Method—Quantitative with the following modifications:

Procedure— Divide the rabbits into four equal groups of two rabbits each.

Calculation— Proceed as directed for Calculation under Rabbit Blood Sugar Method—Quantitative, but do not determine the confidence interval of the log-relative potency,  $M'$ .

Interpretation— If the potency value obtained is not less than 15 USP Units per mg, the Bioidentity Test requirement is met. If the potency value is less than 15 USP Units per mg, repeat the test using eight more rabbits. If the average potency of the two sets of tests is not less than 15 USP Units per mg, the requirement of the test is met.

## Appendix—Fieller's Theorem for Determining the Confidence Interval for a Ratio

This version of Fieller's Theorem is for the case where the numerator and denominator are uncorrelated. The equation assumes the numerator and denominator are normally distributed and the groups of rabbits are equal-sized.

Then, the 95% confidence interval for the ratio is:

$$(L, U) = \frac{M' \pm \frac{t}{T_b} \sqrt{(1-g)S_N^2 + (M')^2 S_D^2}}{1-g}$$

where  $f$  (degrees of freedom in the standard errors) =  $4(k - 1)$ , where  $k$  is the number of rabbits in a group,  $t$  is the upper 97.5 percentile of the t-distribution with  $f$  degrees of freedom, and

$$g = \frac{t^2 S_D^2}{T_b^2}$$

If  $g \geq 1$ , the denominator is not significantly different from 0 and the formula does not work.

$$S_N = 0.301 \sqrt{k} \sqrt{S_1^2 + S_2^2 + S_3^2 + S_4^2}$$

$$S_D = \sqrt{k} \sqrt{S_1^2 + S_2^2 + S_3^2 + S_4^2}$$

Auxiliary Information— Please [check for your question in the FAQs](#) before contacting USP.

## Introduction

Protein A is coupled to a resin support in order to create protein A affinity chromatography media commonly used in the manufacturing of recombinant therapeutic monoclonal antibodies. Natural protein A is derived from *Staphylococcus aureus* and contains five homologous antibody binding regions and a C-terminal region for cell wall attachment. In addition to naturally derived protein A, recombinant material manufactured in *Escherichia coli*, as well as several engineered versions of the protein, also manufactured recombinantly, have entered the market place. When immobilized on a column, protein A provides a highly efficient and robust purification method for purifying antibodies at various scales. However, protein A ligand from the column can co-elute with the antibody during purification, an effect which is often referred to as protein A leaching. This tendency increases as the chromatography medium ages. Engineered versions of protein A may improve the pH tolerance of the medium, but do not eliminate leaching. It is the current regulatory expectation that leached protein A should be cleared during the purification of antibodies for human use, and manufacturing processes should be validated accordingly. Enzyme-Linked Immunosorbent Assay (ELISA)-based residuals testing is generally employed during process development and validation to assure the efficient removal of residual protein A during process steps following protein A affinity chromatography. In addition, the manufacturer should have a clear understanding and documentation of resin and ligand quality through raw materials qualification and column lifetime studies.

General Chapter 130 describes quality attributes of protein A ligands that are used in chromatography media for the manufacture of therapeutic monoclonal antibodies: Protein A; rProtein A; rProtein A, C-Cys; rProtein A, B4, C-Cys.

## Protein A

C1995H3163N597O697S3

46,760

N-terminal Sequence AQHDEA

C-terminal Sequence IAADNK

Protein A is derived from *Staphylococcus aureus*. The structure is composed of a single polypeptide chain containing four IgG binding domains. With the exception of IgG3, all other human IgGs bind to protein A. Each molecule of Protein A is capable of binding two IgG molecules. It is manufactured as a bulk solution at a concentration of greater than 20 mg protein A per mL with an IgG-binding potency of greater than 95%. Because Protein A is used as an ancillary material in the manufacture of recombinant therapeutic drugs, regulatory requirements differ from those for therapeutic drug products.

Packaging and storage— Store in closed containers at the temperature indicated on the label.

Labeling— Preserve in sealed containers, and store at a temperature of  $-20^{\circ}$  or below.

[USP Reference standards](#) 11— [USP Endotoxin RS](#), [USP Protein A RS](#).

## Identification—

A: SDS-PAGE—It meets the requirements of Identification test A under rProtein A using [USP Protein A RS](#).

B: IgG Binding—It meets the requirements of Identification test B under rProtein A using [USP Protein A RS](#).

[Microbial Enumeration Tests](#) 61 and [Tests for Specified Microorganisms](#) 62— The total aerobic microbial count does not exceed 100 cfu per mL, and the total yeasts and molds count does not exceed 10 cfu per mL.

[Bacterial endotoxins](#) 85— It contains not more than 1 USP Endotoxin Unit per mg of total protein. [note—The Bacterial endotoxins test for Protein A is used to describe the quality of this ancillary material. This test does not define the acceptable level of bacterial endotoxin in the preparation of injectable dosage forms in which Protein A is used.]

Total protein (see [Spectrophotometry and Light-Scattering](#) 851)— Prepare triplicate samples for analysis by diluting Protein A to 3.0 mg per mL in [Water for Injection](#). Measure the absorbance of each sample at 275 nm after correcting for the absorbance using [Water for Injection](#) as the blank. Determine the protein concentration using the equation:

$$\text{Protein concentration (mg per mL)} = (A275 / 0.149)$$

in which A is the absorbance of Protein A at the wavelength of 275 nm and 0.149 is the molar absorptivity. Average the triplicate results, and determine a coefficient of variance (CV):  
the CV is  $\leq 5\%$ .

Limit of common contaminant protein and corresponding assay—

Enterotoxin B— Enterotoxin B is determined using a commercially available microstrip enzyme-immunoassay kit.<sup>1</sup> Wells of the microstrips are coated with sheep antibodies to enterotoxin B. Standard curves are made using the ELISA kit control. The negative controls are wells coated with serum from nonimmunized sheep. The level of enterotoxin is determined from the standard curve. The specification for the enterotoxin B level is  $\leq 1$  ng per mg of total protein.

Chromatographic purity— [note—The size-exclusion chromatographic purity test resolves Protein A from high molecular weight contaminants.]

Mobile phase— Prepare a solution of 50 mM sodium dihydrogen phosphate, pH 6.5 in the following manner. Add  $6.9 \pm 0.1$  g of sodium dihydrogen phosphate into a 1000-mL beaker. Dilute with water to 900 mL, and adjust with 5 M sodium hydroxide to a pH of  $6.50 \pm 0.05$ . Transfer the solution into a 1000-mL volumetric flask, and dilute with water to volume. Pass the solution through a 0.22- $\mu$ m membrane filter.

Column regeneration solution— Prepare a solution of 0.1 M sodium dihydrogen phosphate, pH 3.0 in the following manner. Add  $13.8 \pm 0.1$  g of sodium dihydrogen phosphate into a 1000-mL beaker. Dilute with water to 900 mL, and adjust with hydrochloric acid to a pH of  $3.0 \pm 0.1$ . Transfer the solution into a 1000-mL volumetric flask, and dilute with water to volume. Pass the solution through a 0.22- $\mu$ m membrane filter.

Column storage solution— Mix 100 mL of methanol with 900 mL of water.

Test solution— Dilute Protein A to approximately 1 mg per mL with Mobile phase.

Calibration standards— Using Mobile phase, prepare separate 1 mg per mL solutions of each of the following: thyroglobulin (670 kD), IgG (150 kD), beta lactoglobulin (36 kD), and lysozyme (14 kD).

Standard solution— Prepare a solution containing 1 mg per mL of [USP Protein A RS](#) in Mobile phase.

Chromatographic system (see [Chromatography](#) 621)— The liquid chromatograph is equipped with a 280-nm detector and a 7.8-mm  $\times$  30-cm column that contains packing L33. Equilibrate the column for approximately 30 minutes at 0.5 mL of Mobile phase per minute or until a stable baseline is achieved.

Procedure— Separately inject 100  $\mu$ L of each sample, and run the samples in the following sequence: Calibration standards, thyroglobulin, IgG, beta lactoglobulin, and lysozyme; the Standard solution; and the Test solution. Run the sequence three times isocratically using Mobile phase at 0.5 mL per minute for 30 minutes. Absorbance is detected at 280 nm.

...alyze the 280-nm peak data, and pick the retention time (RT) with the largest peak area. Using the data from the Calibration standards, plot the mean RT versus the log molecular weight to produce the standard curve. The purity should be  $\geq 95\%$  in the main peak. Use the formula from the standard curve to give the log molecular weights of the Test solutions. Convert the log molecular weights of the Test solutions and the Standard solutions to actual molecular weights. The apparent molecular weight of protein A from the Standard solution is between 156 and 205 kDa; and the Protein A from the Test solution is within the same range.

Column cleaning and storage— Rinse the column with 100 mL of Column regeneration solution, and store by flushing with 100 mL of Column storage solution.

rPROTEIN A, C-CYS

C1478H2320N432O503S4

34317.5 Da

N-terminal Sequence AQHDEAQQNA

rProtein A, C-Cys is a recombinant Protein A lacking the C-terminal membrane binding part; instead, a C-terminal cysteine has been introduced for directed immobilization purposes. It has five homologous IgG binding domains identical to the native Protein A and is produced using *Escherichia coli* as the host cell followed by purification with conventional chromatography. rProtein A, C-Cys is manufactured as a bulk solution with an IgG-binding potency of greater than 95%. Because rProtein A, C-Cys is used as an ancillary material in the manufacture of recombinant therapeutic drugs, regulatory requirements differ from those for therapeutic drug products.

Packaging and storage— Store in closed containers at the temperature indicated on the label.

Labeling— Preserve in sealed containers, and store at a temperature of  $-20^{\circ}$  or below.

[USP Reference standards](#) (11) — [USP Endotoxin RS](#). [USP rProtein A, C-Cys RS](#).

Identification—

A: SDS-PAGE—It meets the requirements of Identification test A under rProtein A using [USP rProtein A, C-Cys RS](#).

B: IgG Binding—It meets the requirements of Identification test B under rProtein A using [USP rProtein A, C-Cys RS](#).

[Microbial Enumeration Tests](#) (61) and [Tests for Specified Microorganisms](#) (62)— The total aerobic microbial count does not exceed 100 cfu per mL, and the total yeasts and molds count does not exceed 10 cfu per mL.

[Bacterial endotoxins](#) (85)— It contains not more than 1 USP Endotoxin Unit per mg of total protein. [note—The Bacterial endotoxins test for rProtein A, C-Cys is used to describe the quality of this ancillary material. This test does not define the acceptable level of bacterial endotoxin in the preparation of injectable dosage forms in which rProtein A, C-Cys is used.]

Total protein (see [Spectrophotometry and Light-Scattering](#) (851))— Prepare triplicate samples for analysis by diluting the rProtein A, C-Cys to 3.0 mg per mL in [Water for Injection](#). Measure the absorbance of each sample at 275 nm after correcting for the absorbance using [Water for Injection](#) as the blank. Determine the protein concentration using the equation:

$$\text{Protein concentration (mg per mL)} = (A275 / 0.22)$$

in which A is the absorbance of rProtein A, C-Cys, at the wavelength of 275 nm and 0.22 is the molar absorptivity. Average the triplicate results, and determine a coefficient of variance (CV): the CV is  $\leq 2.5\%$ .

Chromatographic purity— [note—The size-exclusion chromatographic purity test resolves rProtein A, C-Cys from high molecular weight contaminants and low molecular weight contaminants.]

Mobile phase— Prepare a solution of 0.02 M sodium phosphate, pH 7.2 containing 0.15 M sodium chloride in the following manner. Add  $0.96 \pm 0.02$  g of monobasic sodium phosphate hydrate,  $2.32 \pm 0.02$  g of dibasic sodium phosphate dihydrate, and  $8.76 \pm 0.02$  g of sodium chloride into a 1000-mL beaker. Dilute with water to 900 mL, and adjust with 1 M sodium hydroxide to a pH of  $7.2 \pm 0.05$ . Transfer this solution into a 1000-mL volumetric flask, and dilute with water to volume. Pass the solution through a 0.45- $\mu$ m membrane filter.

EDTA solution— Prepare a 20 mM ethylenediaminetetraacetic acid (EDTA) solution by dissolving  $0.74 \pm 0.02$  g of EDTA in 100 mL of Mobile phase.

DTT solution— Prepare a 100 mM dl-dithiothreitol (DTT) solution by dissolving  $1.54 \pm 0.02$  g of DTT in 100 mL of Mobile phase.

Pretreatment solution— Prepare a solution containing a mixture of EDTA solution and DTT solution (1:1, v/v). [note—Prepare fresh just before use.]

Test solution— Dilute rProtein A, C-Cys 1 to 5 in Pretreatment solution, and mix gently. Incubate the sample at  $40^{\circ}$  for 60 minutes.

Chromatographic system (see [Chromatography](#) (621))— The liquid chromatograph is equipped with a 214-nm detector and a 10-mm  $\times$  30-cm column that contains packing L54. Equilibrate the column with at least two column volumes of Mobile phase at a flow rate of 0.4 mL per minute.

Procedure— Inject 100  $\mu$ L of Pretreatment solution, and allow the chromatography to continue for at least two column volumes. Repeat this twice before injecting 100  $\mu$ L of the Test solution. Absorbance is detected at 214 nm. Integrate the main peak from the Test solution run and all other peaks not present in the Pretreatment solution runs. Calculate the percentage of impurities in the portion of the rProtein A, C-Cys taken by the formula:

$$100(r_i / r_s)$$

in which  $r_i$  is the peak response for each impurity; and  $r_s$  is the sum of the responses of all the peaks: the sum of all impurities is not more than 5%; and the Test solution shows a major peak at approximately 35 minutes.

rPROTEIN A

C1917H3039N565O658S3

44.618

N-terminal Sequence FLRPVE

Protein A is a component of the cell wall of *Staphylococcus aureus*. Recombinant Protein A (rProtein A) consists of five homologous immunoglobulin (IgG) binding domains (E, D, A, B, C) followed by a partial X domain sequence. It is expressed in *Escherichia coli* and purified via a column chromatography process. IgG columns are not used in the purification process. It is manufactured as a bulk solution with an IgG-binding potency greater than 95%. Release testing methods and specifications are described below. Because rProtein A is used as an ancillary material in the manufacture of recombinant therapeutic drugs, regulatory requirements differ from those of therapeutic drug products.

Packaging and storage— Store in closed containers at the temperature indicated on the label.

Labeling— The labeling states that the material is of recombinant DNA origin along with the lot number, storage conditions, and the statement "Formulated in [Water for Injection](#)."

[USP Reference standards](#) (11) — [USP Endotoxin RS](#). [USP rProtein A RS](#).

Identification—

A: SDS-PAGE—

Molecular weight marker— Use a suitable molecular weight marker (MWM) containing protein bands between 20 and 200 kDa.

PBS solution— Prepare a solution that contains 8065.0 mg and 200.0 mg of sodium chloride and potassium chloride, respectively, per L of 0.01 M sodium phosphate buffer, pH 7.4.

Sample buffer<sup>2</sup>— Dissolve 0.666 g of tris-hydrochloride, 0.682 g of tris base, 0.800 g of lithium dodecyl sulfate (LDS), 0.006 g of ethylenedinitriol tetraacetic acid (EDTA), and 4 g glycerol in 8 mL of water; add 0.75 mL of 1% Coomassie brilliant blue G-250 (see Coomassie Blue G-250 in Reagents under Reagents, Indicators, and Solutions) solution and 0.25 mL of 1% phenol red solution. Mix well, and adjust the volume with water to 10 mL.

2X Sample buffer— Prepare a mixture of 4X Sample buffer and water (1:1).

1X Sample buffer— Prepare a mixture of 2X Sample buffer and water (1:1).

1 M Dithiothreitol solution— Dissolve 0.154 g of dl-dithiothreitol (DTT) in 1 mL of water.

2X Reducing sample buffer— Mix 180  $\mu$ L of 2X Sample buffer and 20  $\mu$ L of 1 M Dithiothreitol solution.

20X Running buffer<sup>3</sup>— Dissolve 104.6 g of 3-(N-morpholino)propanesulfonic acid (MOPS), 60.6 g of tris base, 10 g of sodium dodecyl sulfate (SDS), and 3.0 g of EDTA in 400 mL of water. Mix well, and adjust with water to 500 mL.

1X Running buffer— Prepare a solution of water and 20X Running buffer (19:1).

Gel staining solution— Prepare a solution of Coomassie brilliant blue R-250 (see Coomassie Brilliant Blue R-250 in Reagents under Reagents, Indicators, and Solutions) having a concentration of 0.5 g per L in a mixture of water, isopropanol, and acetic acid (6.5:2.5:1.0). Filter, and store at room temperature. Silver staining is not recommended.

Destaining solution— Mix 100 mL of acetic acid with 900 mL of water.

Standard preparation— Dilute [USP rProtein A RS](#) to 0.4 mg per mL with PBS solution. Further dilute this solution 1:1 with 2X Reducing sample buffer, and incubate in a closed tube for 5 minutes at 90°. Mix, and quick spin prior to loading.

Test preparation— Dilute rProtein A with PBS solution to 0.4 mg per mL. Proceed as directed under Standard preparation beginning with "Further dilute."

Comix solution— Dilute rProtein A and [USP rProtein A RS](#) with PBS solution to 0.8 mg per mL. This solution contains 0.4 mg per mL of each protein. Proceed as directed under Standard preparation beginning with "Further dilute."

SDS-PAGE gel and apparatus set-up— Assemble gel apparatus following the manufacturer's instructions. Lock the gel tension wedge in place, and fill approximately 200 mL of 1X Running buffer into the inside chamber. If there are no leaks, pour 600 mL of 1X Running buffer into the outer chamber. Gently pull the comb out of the cassette to immerse the wells in 1X Running buffer. Load 10  $\mu$ L of each preparation as directed below under Gel loading onto a 10% Bis-Tris SDS-PAGE gel.<sup>4</sup>

Gel loading— Use the following gel loading scheme when running one Test preparation (see [Table 1](#)). Each Test preparation is run by itself and as part of the Comix solution that contains the rProtein A and [USP rProtein A RS](#).

Table 1

Lane	Sample	Load Volume ( $\mu$ L)	Load Amount ( $\mu$ g)
1	1X Sample buffer	10	N/A
2	MWM	20	N/A
3	Test preparation #1	10	2
4	Comix solution #1	10	4 (total)
5	Test preparation #1	10	2
6	1X Sample buffer	10	N/A
7	Standard preparation	10	2
8	MWM	20	N/A
9	—	—	—
10	—	—	—

Running the gel— Set the voltage to 125 volts, and run at a constant voltage. Run the gels until the bromophenol blue band is approximately 5 mm from the bottom of the gel (approximately 120 to 140 minutes).

Gel staining— Pour approximately 100 mL of Gel staining solution into the staining container. Place the gel into the staining container, and allow the stain to completely cover the gel. Cook the gel and container in a microwave for 30 seconds. Place the staining container on an orbital shaker, and stain the gel for 1 hour with gentle shaking.

Destaining— Drain the Gel staining solution, and add enough Destaining solution to the container to cover the gel. Place the container on an orbital shaker, and shake at low speed. Change the Destaining solution as necessary until a clear background is obtained. After destaining, rinse the gel thoroughly with water, and leave the gel in water for 10 minutes before scanning.

Gel scanning— Apply some water to the glass plate of the scanner, and place the gels on a wetted glass plate. Eliminate any bubbles. Using appropriate settings, scan the gels.

Data analysis— Choose a band between the 20 kD and 30 kD bands of the MWM to calculate the percentage of the retention factor. Draw a line in one lane (lane containing 1X Sample buffer) from the well to the apex (region of greatest intensity) of the chosen band.

The length of this line is denoted as the total distance (DT). For the lanes containing samples draw a line from the well to the apex of each band. For each band the length of this distance is the migration distance (DM) in mm. Record the DT and DM on the report sheet for each peak or band. The total distance should be the same for each lane on a gel. Calculate the percentage of the retention factor (RF) of each major peak or band, and document on the report sheet using the following equation:

$$\%RF = DM / DT \times 100$$

Also for each gel, record the number of bands and approximate molecular weight of each band in each sample.

System suitability— All bands between 20 kD and 70 kD are present. The lane containing 1X Sample buffer does not contain any bands.

Specificity— The rProtein A has one major band and a similar molecular weight that corresponds to those of the [USP rProtein A RS](#). The Comix solution also shows a single major band.

B: IgG Binding—[note—The IgG binding assay is a functional method for determining the percentage of rProtein A capable of binding to immobilized human polyclonal immunoglobulin. Since the percent of functional rProtein A in each lot is not less than 95%, the assay measures unbound protein versus total protein injected. This is done by comparing the absorbance in the flow-through to absorbance from an injection bypassing the column.]

Sample pretreatment (desalting)— In order to remove any buffer components that may contribute to absorbance in the "unbound" IgG column fraction, samples are desalted with Solution A. Desalting may be performed using a suitable desalting column<sup>5</sup> depending on the volumes required.

IgG column— A 1-mL Sepharose column<sup>6</sup> with immobilized human polyclonal IgG (IgG) is required to perform this assay. [note—The IgG column requires washing when it is new, when it has performed several analysis cycles, or after system suitability failure. Column washing procedure is not required for each sample injection.]

Column washing solution A— Prepare a solution of 0.5 M acetic acid, pH 3.4 by adding 28.6 mL of acetic acid into a 1000-mL beaker, diluting to 900 mL with water, and adjusting with ammonium acetate to a pH of 3.4. Transfer the solution into a 1000-mL volumetric flask, and dilute with water to volume. Pass the solution through a 0.45- $\mu$ m membrane filter.

Column washing solution B— Prepare a solution of 50 mM Tris, pH 7.6, 150 mM sodium chloride, and 0.05% Tween 20 by the following procedure. Add 6.06  $\pm$  0.01 g of Tris and 8.77

0.01 g of sodium chloride into a 1000-mL beaker. Dilute with water to 900 mL, and adjust with 0.5 M sodium hydroxide to a pH of  $7.60 \pm 0.05$ . Transfer the solution into a 1000-mL volumetric flask, and dilute with water to volume. Pass the solution through a 0.45- $\mu\text{m}$  membrane filter (buffer solution). Add 0.5 mL of Tween 20 into 1 L of the buffer solution and mix thoroughly.

**Solution A**— Prepare a solution of 20 mM monobasic sodium phosphate and 150 mM sodium chloride, pH 7.6 by the following procedure. Add  $2.76 \pm 0.01$  g monobasic sodium phosphate hydrate and  $8.77 \pm 0.01$  g sodium chloride into a 1000-mL beaker. Dilute with water to 900 mL, and adjust with 5 M sodium hydroxide to a pH of  $7.60 \pm 0.05$ . Transfer the solution into a 1000-mL volumetric flask, and dilute with water to volume. Pass the solution through a 0.45- $\mu\text{m}$  membrane filter.

**Solution B**— Prepare a solution of 100 mM phosphoric acid pH 2.8 by the following procedure. Add 6.8 mL of phosphoric acid into a 1000-mL beaker. Dilute with water to 900 mL, and adjust with 2 M potassium hydroxide to a pH of  $2.80 \pm 0.05$ . Transfer the solution into a 1000-mL volumetric flask, and dilute with water to volume.

**Mobile phase**— Use variable mixtures of Solution A and Solution B as directed for Chromatographic system. Make adjustments if necessary (see System Suitability under [Chromatography \(621\)](#)).

**Standard preparation**— Thaw [USP rProtein A RS](#), and use directly.

**Test preparation**— Prepare a 4.0 to 6.0 mg per mL rProtein A solution in Solution A.

**Chromatographic system**— The liquid chromatograph is equipped with a 280-nm detector and a 1-mL column with immobilized hIgG. The chromatograph is equipped with a bypass valve to allow flow to be diverted from the column. Each analysis consists of a series of two injections, one where the sample is injected onto the column and one where the sample bypasses the column and flows directly into the detector. Perform three replicate analyses. The chromatograph is programmed as follows (see Table 2).

Table 2

Flow Rate (mL per minute)	Time (minutes)	Solution A (%)	Solution B (%)	Valve Position	Elution
1.0	0–6	100	0	column	re-equilibration
1.0	6–12	100→0	0→100	column	re-equilibration
1.0	12–22	100	0	column	equilibration
0.4	22–25	100	0	column	equilibration
0.4 (sample injected)	25–35	100	0	column	isocratic
1.0	35–49	100→0	0→100	column	regeneration
1.0	49–63	0→100	100→0	column	re-equilibration
1	63–65	100	0	bypass	equilibration
0.4	65–68	100	0	bypass	equilibration
0.4 (sample injected)	68–75	100	0	bypass	isocratic

Chromatograph the Standard preparation, record the peak responses, and calculate the percentage of hIgG binding as directed for Procedure: the percentage of hIgG binding  $\geq 95\%$  and the relative standard deviation for replicate analysis is not more than 1%.

**Procedure**— Inject a volume (about 100  $\mu\text{L}$ ) of the Test preparation. Record the chromatogram, and measure the peak responses. Calculate the percentage of hIgG binding activity by the following formula:

$$100 - 100(rC / rB)$$

in which rC is the unbound material peak response from the column injection and rB is the bypass peak response from the bypass injection. Each replicate analysis of the Test preparation is not less than 95% of hIgG binding. Report the average value from three replicate analyses.

[Microbial Enumeration Tests \(61\)](#) and [Tests for Specified Microorganisms \(62\)](#)— The total aerobic microbial count does not exceed 100 cfu per mL, and the total yeasts and molds count does not exceed 10 cfu per mL.

[Bacterial endotoxins \(85\)](#)— It contains not more than 0.5 USP Endotoxin Unit per mg of total protein. [note—The Bacterial endotoxins test for rProtein A is used to describe the quality of this ancillary material. This test does not define the acceptable level of bacterial endotoxin in the preparation of injectable dosage forms in which rProtein A is used.]

Total protein (see [Spectrophotometry and Light-Scattering \(851\)](#))— Prepare triplicate samples for analysis by diluting the rProtein A to 3.0 mg per mL in [Water for Injection](#). Measure the absorbance of each sample at 275 nm after correcting for the absorbance using [Water for Injection](#) as the blank. Determine the protein concentration using the equation:

$$\text{Protein concentration (mg per mL)} = (A275 / 0.165)$$

in which A is the absorbance of rProtein A at the wavelength of 275 nm and 0.165 is the molar absorptivity. Average the triplicate results, and determine a coefficient of variance (CV): the CV is  $\leq 5\%$ .

UV spectral analysis— Dilute rProtein A to 1 mg per mL in [Water for Injection](#). Using a scanning UV spectrophotometer and [Water for Injection](#) as the blank, obtain spectral scans over the range of 240 to 360 nm. From the resulting data, calculate the absorbance value at 270 nm and the ratio of absorbance at 270 to 250 nm (i.e., E270/E250): the absorbance at 270 nm of a 1 mg per mL solution of rProtein A in [Water for Injection](#) is within the range 0.14–0.20.

Chromatographic purity— [note—The size-exclusion chromatographic purity test resolves rProtein A from high molecular weight contaminants.]

Mobile phase— A solution of 0.3 M sodium phosphate, pH 7 is prepared by mixing monobasic and dibasic phosphate solutions in the following manner. Weigh  $21.3 \pm 0.1$  g of dibasic anhydrous sodium phosphate, and dissolve in 500 mL of water to obtain a 0.3 M dibasic sodium phosphate solution (Solution 1). Into a separate container, weigh  $18.0 \pm 0.1$  g monobasic anhydrous sodium phosphate, and dissolve in 500 mL of water to obtain a 0.3 M monobasic sodium phosphate solution (Solution 2). Calibrate a pH meter using pH calibrators at a pH of 7 and 10. Add 400 mL of Solution 1 to a 1-L beaker. Transfer the pH probe to the beaker. Slowly add Solution 2 to the solution until the pH is  $7.0 \pm 0.1$ . Pass the solution through a 0.45- $\mu\text{m}$  membrane filter.

Standard solution— Dilute [USP rProtein A RS](#) to 1 mg per mL in Mobile phase.

Test solution— Dilute rProtein A to 1 mg per mL in Mobile phase.

Chromatographic system (see [Chromatography \(621\)](#))— The liquid chromatograph is equipped with a 214-nm and 280-nm detector and a 9.4-mm  $\times$  25-cm column that contains packing L35. The flow rate is 1 mL per minute. Chromatograph the Standard solution as directed for Procedure: rProtein A shows a single major peak at approximately 9 minutes and the area percentage is  $\geq 98\%$  at 214 nm and  $\geq 95\%$  at 280 nm.

**Procedure**— Inject 100  $\mu\text{L}$  of the Test solution into the chromatograph, run isocratically for 15 minutes, and record the chromatogram. The values for the rProtein A from the Test solution correspond to the specifications of the [USP rProtein A RS](#) from the Standard solution.

Isoforms—

Standard solution— Thaw [USP rProtein A RS](#), and use directly.

Test solution— Dilute rProtein A to 4 mg per mL in [Water for Injection](#).

pl Markers— Use a suitable marker set containing markers between 3 and 10.<sup>7</sup>

IEF gel— Use a suitable gel with the range of between 3 and 10 and a size of  $100 \times 125 \text{ mm}$ .<sup>8</sup>

Procedure— Apply 5- $\mu\text{L}$  aliquots of the *pl* Markers, Test solution, and the Standard solution to the IEF gel, and run under 1W of power for approximately 10 minutes. Remove the sample mask, and apply power with concurrent cooling between  $5^{\circ}$  to  $10^{\circ}$  of the focusing chamber for 40 minutes at a setting of 1000V, 20 mA, 25W. Fix the IEF gel for 1 hour in 20% trichloroacetic acid, then stain using a suitable stain for IEF gels.<sup>9</sup> Finally, wash and dry the gel: the correlation coefficient of the best fit line for the *pl* Markers versus their migration in cm is  $\geq 0.990$ , and the rProtein A from the Standard solution shows a single major band within the *pl* range of 4.6 to 5.2. A single band is seen in the Test solution that corresponds to the *pl* range of the Standard solution.

#### Limit of Triton X-100—

Mobile phase— Prepare a filtered and degassed mixture of water and acetonitrile (60:40).

Test solution— Dilute rProtein A to 5 mg per mL in [Water for Injection](#).

Triton X-100 spike solution— Combine 5 mg per mL of [USP rProtein A RS](#) and 0.15% Triton X-100 (9:1) to obtain a solution having known concentrations of rProtein A and 0.015% Triton X-100.

Chromatographic system (see [Chromatography](#))— The liquid chromatograph is equipped with a 214-nm and a 280-nm detector and a 4.6-mm  $\times$  25-cm column that contains 5- $\mu\text{m}$  packing L11. The flow rate is 1 mL per minute. Chromatograph the Triton X-100 spike solution as directed for Procedure: Triton X-100 has a single major peak at approximately 9 minutes, and the rProtein A shows a smaller or undetectable peak at the same retention time.

Procedure— Inject about 100  $\mu\text{L}$  of the Test solution into the chromatograph, run isocratically for 35 minutes, and record the chromatogram. The absorbance is detected at 223 nm: the Triton X-100 peak is not more than 0.015% (equivalent to the Triton X-100 spike solution).

rPROTEIN A, B<sub>4</sub>, C-CYS

C1177H1854N326O384S1

26747.6 Da

N-terminal Sequence AQGTVDAKFD

rProtein A, B<sub>4</sub>, C-Cys is a recombinant protein derived from the B-domain of Protein A. The Protein A domain has been alkali-stabilized by site-specific mutagenesis and multimerized to a tetramer with a C-terminal cysteine for directed immobilization purposes. rProtein A, B<sub>4</sub>, C-Cys is produced using *Escherichia coli* as the host cell followed by purification with conventional chromatography. rProtein A, B<sub>4</sub>, C-Cys is manufactured as a bulk solution with an IgG-binding potency of greater than 95%. Because rProtein A, B<sub>4</sub>, C-Cys is used as an ancillary material in the manufacture of recombinant therapeutic drugs, regulatory requirements differ from those for therapeutic drug products.

Packaging and storage— Store in closed containers at the temperature indicated on the label.

Labeling— Preserve in sealed containers, and store at a temperature of  $-20^{\circ}$  or below.

[USP Reference standards](#)— [USP Endotoxin RS](#). USP rProtein A, B<sub>4</sub>, C-Cys RS.

#### Identification—

A: SDS-PAGE—It meets the requirements of Identification test A under rProtein A using USP rProtein A, B<sub>4</sub>, C-Cys RS.

B: IgG Binding—It meets the requirements of Identification test B under rProtein A using USP rProtein A, B<sub>4</sub>, C-Cys RS.

[Microbial Enumeration Tests](#) and [Tests for Specified Microorganisms](#)— The total aerobic microbial count does not exceed 100 cfu per mL, and the total yeasts and molds count does not exceed 10 cfu per mL.

[Bacterial endotoxins](#)— It contains not more than 1 USP Endotoxin Unit per mg of total protein. [note—The Bacterial endotoxins test for rProtein A, B<sub>4</sub>, C-Cys is used to describe the quality of this ancillary material. This test does not define the acceptable level of bacterial endotoxin in the preparation of injectable dosage forms in which rProtein A, B<sub>4</sub>, C-Cys is used.]

#### Total protein (see [Spectrophotometry and Light-Scattering](#))—

Formulation buffer solution— Prepare a solution of 0.02 M potassium phosphate, pH 7.0, containing 0.15 M potassium chloride and 2 mM of ethylenediaminetetraacetic acid (EDTA) in the following manner. Add  $2.72 \pm 0.01$  g of monobasic potassium phosphate anhydrous,  $11.18 \text{ g} \pm 0.22$  g of potassium chloride, and  $0.744 \pm 0.02$  g of EDTA into a 1000-mL beaker. Dilute with water to 900 mL, and adjust with 1 M sodium hydroxide to a pH of  $7.00 \pm 0.05$ . Transfer the solution into a 1000-mL volumetric flask, and dilute with water to volume. Pass the solution through a 0.45- $\mu\text{m}$  membrane filter.

Test preparation— Dilute the rProtein A, B<sub>4</sub>, C-Cys to 3.0 mg per mL with Formulation buffer solution.

Procedure— Prepare triplicate samples for analysis. Measure the absorbance of each Test preparation at 275 nm after correcting for the absorbance using the Formulation buffer solution as the blank. Determine the protein concentration using the equation:

$$\text{Protein concentration (mg per mL)} = (A275 / 0.22)$$

in which A is the absorbance of rProtein A, B<sub>4</sub>, C-Cys, at the wavelength of 275 nm and 0.22 is the molar absorptivity. Average the triplicate results, and determine a coefficient of variance (CV): the CV  $\leq 2.5\%$ .

Chromatographic purity— [note—The size-exclusion chromatographic purity test resolves rProtein A, B<sub>4</sub>, C-Cys from high molecular weight contaminants and low molecular weight contaminants.]

Mobile phase— Prepare a solution of 0.02 M sodium phosphate, pH 7.2 containing 0.15 M sodium chloride in the following manner. Add  $0.96 \pm 0.02$  g of monobasic sodium phosphate hydrate,  $2.32 \pm 0.02$  g of dibasic sodium phosphate dihydrate, and  $8.76 \text{ g} \pm 0.02$  g of sodium chloride into a 1000-mL beaker. Dilute with water to 900 mL, and adjust with 1 M sodium hydroxide to a pH of  $7.2 \pm 0.05$ . Transfer this solution into a 1000-mL volumetric flask, and dilute with water to volume. Pass the solution through a 0.45- $\mu\text{m}$  membrane filter.

EDTA solution— Prepare a 20 mM EDTA solution by dissolving  $0.74 \pm 0.02$  g of EDTA in 100 mL of Mobile phase.

DTT solution— Prepare a 100 mM di-dithiothreitol (DTT) solution by dissolving  $1.54 \pm 0.02$  g of DTT in 100 mL of Mobile phase.

Pretreatment solution— Prepare a solution containing a mixture of EDTA solution and DTT solution (1:1, v/v). [note—Prepare fresh just before use.]

Test solution— Dilute rProtein A, B<sub>4</sub>, C-Cys 1 to 5 in Pretreatment solution, and mix gently. Incubate the sample at  $40^{\circ}$  for 60 minutes.

Chromatographic system (see [Chromatography](#))— The liquid chromatograph is equipped with a 214-nm detector and a 10-mm  $\times$  30-cm column that contains packing L54. Equilibrate the column with at least two column volumes of Mobile phase at a flow rate of 0.4 mL per minute.

Procedure— Inject 100  $\mu\text{L}$  of Pretreatment solution, and allow the chromatography to continue for at least two column volumes. Repeat this twice before injecting 100  $\mu\text{L}$  of the Test solution. Absorbance is detected at 214 nm. Integrate the main peak from the Test solution run and all other peaks not present in the Pretreatment solution runs. Calculate the percentage of impurities in the portion of rProtein A, B<sub>4</sub>, C-Cys taken by the formula:

$$100(r_i / r_s)$$

in which  $r_i$  is the peak response for each impurity; and  $r_s$  is the sum of all the responses of all the peaks: the sum of all impurities is not more than 5%; and the Test solution shows a major peak at approximately 37 minutes.

1 A suitable enzyme immunoassay kit is available from TECRA International Pty Ltd., Australia (No. SETVIA96).

2 4X NuPAGE LDS sample buffer is available from Invitrogen (No. NP0007).

3 20X NuPAGE MOPS SDS Running Buffer is available from Invitrogen (No. NP0001).

4 10% Bis-Tris SDS-PAGE gel is available from Invitrogen (No. NP0301).

5 Zeba columns are available from Pierce; Nap-10 columns are available from GE Healthcare.

6 HiTrap IgG Sepharose 6 FF column is available from GE Healthcare (No. 90-1003-97).

7 pI markers in the 3–10 range are available from BioRad (No. 161-0310).

8 IEF gels in the 3–10 range are available from Cambrex (No. 56015).

9 ISS Pro-Blue is available from Integrated Separation Systems.

Auxiliary Information— Please [check for your question in the FAQs](#) before contacting USP.

#### 141 PROTEIN—BIOLOGICAL ADEQUACY TEST

This test is intended for the evaluation of the biological adequacy, as an index to the completeness of the mixture of amino acids contained, of Protein Hydrolysate Injection.

##### Depletion Diet—

	Parts by Weight
Dextrin	83.9
Corn Oil	9.0
Salt Mixture	4.0
Agar	2.0
Cod Liver Oil	1.0
Choline Chloride	0.15
Inositol	0.10
Calcium Pantothenate	0.002
Niacinamide	0.0015
Riboflavin	0.0003
Pyridoxine	0.00025
Thiamine	0.0002
p-Aminobenzoic Acid	0.0002
Folic Acid	0.0002
Menadione	0.0002
Biotin	0.00002

Salt Mixture— Prepare the salt mixture specified in the Depletion Diet as follows:

Sodium Chloride	139.3 g
Potassium Biphosphate	389.0 g
Magnesium Sulfate, Anhydrous	57.3 g
Calcium Carbonate	381.4 g
Ferrous Sulfate	27.0 g
Manganese Sulfate	4.01 g
Potassium Iodide	0.79 g
Zinc Sulfate	0.548 g
Cupric Sulfate	0.477 g
Cobaltous Chloride	0.023 g

Place a portion of the weighed quantity of sodium chloride in a suitable mortar and add, with grinding, the potassium iodide. Set aside the mixture, and mix in a similar manner all the other salts with the remainder of the sodium chloride, adding finally the previously mixed sodium chloride and potassium iodide. Reduce the entire mixture to a fine powder (see

[Powder Fineness](#) 811).

Control Nitrogen Supplement Mixture— Place 50 g of calcium caseinate and 46 g of anhydrous dextrose in a beaker, add sufficient water to make a paste, and finally add 1000 mL of

water. Heat the solution between 70° and 82° for 5 minutes with stirring, and cool. Determine nitrogen on an aliquot using [Nitrogen Determination—Method I](#) or [Method II](#) (461). Store in a refrigerator. Mix before removing portions for analysis or use.

**Depletion and Control Periods**— Select a group of not less than six male rats 2 to 4 months of age and each weighing between 190 g and 225 g. Place the rats in individual cages with free access to water and the Depletion Diet for 12 days. Weigh the depleted rats, and discard any rat that weighs more than 90% of its starting weight.

For the next 3 days substitute as drinking water the Control Nitrogen Supplement Mixture in a quantity equivalent to 0.12 g of nitrogen per rat per day, diluted with water to 20 mL, and offered at the same time each morning either in a dish suitable for preventing spillage or in a reservoir fitted with a drinking tube. Remove all drinking water from the cages of the depleted rats during each feeding, and return it after the supplement has been consumed or is removed. On the third day, weigh each rat. Discard any rats that have not consumed all of the Control Nitrogen Supplement Mixture.

For the next 3 days, replace the Control Nitrogen Supplement Mixture with water ad libitum, and continue the rats on the Depletion Diet. Weigh the rats, and discard any that have not lost weight since the previous weighing.

**Procedure**— Assemble not less than six rats that have completed the depletion and control periods. For 5 days maintain the assembled rats on the Depletion Diet with a daily supplement of 20 mL, accurately measured, of a solution containing the Protein Hydrolysate Injection in an amount equivalent to 0.12 g of nitrogen offered each morning in the same way as the Control Nitrogen Supplement Mixture was offered previously. Withhold water for at least 2 hours prior to offering the supplement and for 4 hours afterward. Then if the supplement has been consumed, offer water ad libitum.

On the afternoon of the fifth day, weigh each rat, and compare the respective final and starting weights. Not fewer than 80% of the group of rats used gain weight or maintain their weight during the test.

Auxiliary Information— Please [check for your question in the FAQs](#) before contacting USP.

USP32-NF27 Page 123

### 151 PYROGEN TEST

The pyrogen test is designed to limit to an acceptable level the risks of febrile reaction in the patient to the administration, by injection, of the product concerned. The test involves measuring the rise in temperature of rabbits following the intravenous injection of a test solution and is designed for products that can be tolerated by the test rabbit in a dose not to exceed 10 mL per kg injected intravenously within a period of not more than 10 minutes. For products that require preliminary preparation or are subject to special conditions of administration, follow the additional directions given in the individual monograph or, in the case of antibiotics or biologics, the additional directions given in the federal regulations (see [Biologics](#) (1041)).

#### APPARATUS AND DILUENTS

Render the syringes, needles, and glassware free from pyrogens by heating at 250° for not less than 30 minutes or by any other suitable method. Treat all diluents and solutions for washing and rinsing of devices or parenteral injection assemblies in a manner that will assure that they are sterile and pyrogen-free. Periodically perform control pyrogen tests on representative portions of the diluents and solutions for washing or rinsing of the apparatus. Where Sodium Chloride Injection is specified as a diluent, use Injection containing 0.9 percent of NaCl.

#### TEMPERATURE RECORDING

Use an accurate temperature-sensing device such as a clinical thermometer, or thermistor probes or similar probes that have been calibrated to assure an accuracy of  $\pm 0.1^{\circ}$  and have been tested to determine that a maximum reading is reached in less than 5 minutes. Insert the temperature-sensing probe into the rectum of the test rabbit to a depth of not less than 7.5 cm, and, after a period of time not less than that previously determined as sufficient, record the rabbit's body temperature.

#### TEST ANIMALS

Use healthy, mature rabbits. House the rabbits individually in an area of uniform temperature between 20° and 23° and free from disturbances likely to excite them. The temperature varies not more than  $\pm 3^{\circ}$  from the selected temperature. Before using a rabbit for the first time in a pyrogen test, condition it not more than seven days before use by a sham test that includes all of the steps as directed for Procedure except injection. Do not use a rabbit for pyrogen testing more frequently than once every 48 hours, nor prior to 2 weeks following a maximum rise of its temperature of 0.6° or more while being subjected to the pyrogen test, or following its having been given a test specimen that was adjudged pyrogenic.

#### PROCEDURE

Perform the test in a separate area designated solely for pyrogen testing and under environmental conditions similar to those under which the animals are housed and free from disturbances likely to excite them. Withhold all food from the rabbits used during the period of the test. Access to water is allowed at all times, but may be restricted during the test. If rectal temperature-measuring probes remain inserted throughout the testing period, restrain the rabbits with light-fitting neck stocks that allow the rabbits to assume a natural resting posture. Not more than 30 minutes prior to the injection of the test dose, determine the "control temperature" of each rabbit: this is the base for the determination of any temperature increase resulting from the injection of a test solution. In any one group of test rabbits, use only those rabbits whose control temperatures do not vary by more than 1° from each other, and do not use any rabbit having a temperature exceeding 39.8°.

Unless otherwise specified in the individual monograph, inject into an ear vein of each of three rabbits 10 mL of the test solution per kg of body weight, completing each injection within 10 minutes after start of administration. The test solution is either the product, constituted if necessary as directed in the labeling, or the material under test treated as directed in the individual monograph and injected in the dose specified therein. For pyrogen testing of devices or injection assemblies, use washings or rinsings of the surfaces that come in contact with the parenterally administered material or with the injection site or internal tissues of the patient. Assure that all test solutions are protected from contamination. Perform the injection after warming the test solution to a temperature of  $37 \pm 2^{\circ}$ . Record the temperature at 30-minute intervals between 1 and 3 hours subsequent to the injection.

#### TEST INTERPRETATION AND CONTINUATION

Consider any temperature decreases as zero rise. If no rabbit shows an individual rise in temperature of 0.5° or more above its respective control temperature, the product meets the requirements for the absence of pyrogens. If any rabbit shows an individual temperature rise of 0.5° or more, continue the test using five other rabbits. If not more than three of the eight rabbits show individual rises in temperature of 0.5° or more and if the sum of the eight individual maximum temperature rises does not exceed 3.3°, the material under examination meets the requirements for the absence of pyrogens.

## RADIOACTIVE PHARMACEUTICALS

Test Dose for Preformulated, Ready-to-Use Products Labeled with Radioactivity  
aggregated albumin and other particle-containing products

For the rabbit pyrogen test, dilute the product with Sodium Chloride Injection to not less than 100  $\mu$ Ci per mL, and inject a dose of 3 mL per kg of body weight into each rabbit.

other products

Where Physical Half-life of Radionuclide Is Greater Than 1 Day— Calculate the maximum volume of the product that might be injected into a human subject. This calculation takes into account the maximum recommended radioactive dose of the product, in  $\mu$ Ci, and the radioactive assay, in  $\mu$ Ci per mL, of the product at its expiration date or time. Using this information, calculate the maximum volume dose per kg to a 70-kg human subject.

For the rabbit pyrogen test, inject a minimum of 10 times this dose per kg of body weight into each rabbit. If necessary, dilute with Sodium Chloride Injection. The total injected volume per rabbit is not less than 1 mL and not more than 10 mL of solution.

Where Physical Half-life of Radionuclide is Less Than 1 Day— For products labeled with radionuclides having a half-life of less than 1 day, the dosage calculations are identical to those described in the first paragraph under Other Products. These products may be released for distribution prior to completion of the rabbit pyrogen test, but such test shall be initiated at not more than 36 hours after release.

## Test Dose for Pharmaceutical Constituents or Reagents to Be Labeled

The following test dose requirements pertain to reagents that are to be labeled or constituted prior to use by the direct addition of radioactive solutions such as Sodium Pertechnetate Tc 99m Injection, i.e., "cold kits".

Assume that the entire contents of the vial of nonradioactive reagent will be injected into a 70-kg human subject, or that 1/70 of the total contents per kg will be injected. If the contents are dry, constitute with a measured volume of Sodium Chloride Injection.

For the rabbit pyrogen test, inject (1/7) of the vial contents per kg of body weight into each rabbit. The maximum dose per rabbit is the entire contents of a single vial. The total injected volume per rabbit is not less than 1 mL and not more than 10 mL of solution.

Auxiliary Information— Please [check for your question in the FAQs](#) before contacting USP.

Topic/Question	Contact	Expert Committee
General Chapter	<a href="#">Radhakrishna S Tirumalai, Ph.D.</a> Senior Scientist 1-301-816-8339	(MSA05) Microbiology and Sterility Assurance

USP32-NF27 Page 124

## 161 TRANSFUSION AND INFUSION ASSEMBLIES AND SIMILAR MEDICAL DEVICES

The requirements apply to sterile and nonpyrogenic assemblies or devices in contact directly or indirectly with the cardiovascular system, the lymphatic system, or cerebrospinal fluid. This includes, but is not limited to, solution administration sets, extension sets, transfer sets, blood administration sets, intravenous catheters, implants extracorporeal oxygenator tubings and accessories, dialysers and dialysis tubing and accessories, heart valves, vascular grafts, intramuscular drug delivery catheters, and transfusion and infusion assemblies.

These requirements do not apply to orthopedic products, latex gloves, or wound dressings.

Sterility— Proceed as directed for Sterilized Devices under [Sterility Tests](#) 71.

Bacterial Endotoxins— Proceed as directed under [Bacterial Endotoxins Test](#) 85.

For medical devices, the endotoxin limit is not more than 20.0 USP Endotoxin Units per device except that for those medical devices in contact with the cerebrospinal fluid the limit is not more than 2.15 USP Endotoxin Units per device.

A device that fails this test can be retested once by another Bacterial Endotoxins test. For devices that cannot be tested by the [Bacterial Endotoxins Test](#) 85 because of nonremovable inhibition or enhancement, the [Pyrogen Test](#) 151 is applied.

Preparation of Devices— Select not less than 3 and not more than 10 devices. Rinse or soak the devices with LAL Reagent Water. The volume of rinsing or extracting solution may be adjusted for the size and configuration of the device.

For devices labeled "nonpyrogenic fluid pathway," flush the fluid pathway with extracting fluid that has been heated to  $37 \pm 1.0^{\circ}$ , keeping the extracting fluid in contact with the relevant pathway for not less than 1 hour at controlled room temperature. Extracts may be combined, where appropriate. The endotoxin limit for the rinsing or extracting solution is calculated by the formula:

$$(K \times N) / (V)$$

where K is equal to the amount of endotoxin allowed per device, N is equal to the number of devices tested, and V is equal to the total volume of the extract or rinse. If the undiluted rinsing or extracting solution is unsuitable for the [Bacterial Endotoxins Test](#) 85, repeat the inhibition or enhancement test after neutralization and removal of the interfering substances or after the solution has been diluted by a factor not exceeding the Maximum Valid Dilution. The Maximum Valid Dilution for devices is calculated by dividing the endotoxin limit by the labeled sensitivity  $\lambda$  of the LAL reagent used.

Pyrogen— For samples that cannot be tested by the Bacterial Endotoxins Test because of nonremovable inhibition or enhancement of the test, the [Pyrogen Test](#) 151 is applied. Select 10 devices, and obtain a pooled effluent, utilizing preparation methods appropriate to the device as directed for Bacterial Endotoxins, but with volumes of rinse or extraction fluid not to exceed 40 mL of sterile saline TS per device. The requirements of the [Pyrogen Test](#) 151 are met.

Other Requirements— The portions of medical devices that are made of plastics or other polymers meet the requirements specified for Biological Tests—Plastics and Other Polymers under [Containers—Plastics](#) 661; those made of elastomers meet the requirements under [Elastomeric Closures for Injections](#) 381. If a class designation for elastomers, plastics, or other polymers is needed, perform the appropriate in vivo tests indicated in the general test chapter [Biological Reactivity Tests, In Vivo](#) 88.

Auxiliary Information— Please [check for your question in the FAQs](#) before contacting USP.

## 171 VITAMIN B12 ACTIVITY ASSAY

USP Reference Standards 11 — [USP Cyanocobalamin RS](#).

Assay Preparation— Place a suitable quantity of the material to be assayed, previously reduced to a fine powder if necessary and accurately measured or weighed, in an appropriate vessel containing, for each g or mL of material taken, 25 mL of an aqueous extracting solution prepared just prior to use to contain, in each 100 mL, 1.29 g of disodium phosphate, 1.1

g of anhydrous citric acid, and 1.0 g of sodium metabisulfite. Autoclave the mixture at 121° for 10 minutes. Allow any undissolved particles of the extract to settle, and filter or centrifuge, if necessary. Dilute an aliquot of the clear solution with water so that the final test solution contains vitamin B12 activity approximately equivalent to that of the Standard Cyanocobalamin Solution which is added to the assay tubes.

Standard Cyanocobalamin Stock Solution— To a suitable quantity of [USP Cyanocobalamin RS](#), accurately weighed, add sufficient 25 percent alcohol to make a solution having a known concentration of 1.0 µg of cyanocobalamin per mL. Store in a refrigerator.

Standard Cyanocobalamin Solution— Dilute a suitable volume of Standard Cyanocobalamin Stock Solution with water to a measured volume such that after the incubation period as described for Procedure, the difference in transmittance between the inoculated blank and the 5.0-mL level of the Standard Cyanocobalamin Solution is not less than that which corresponds to a difference of 1.25 mg in dried cell weight. This concentration usually falls between 0.01 ng and 0.04 ng per mL of Standard Cyanocobalamin Solution. Prepare a fresh standard solution for each assay.

Basal Medium Stock Solution— Prepare the medium according to the following formula and directions. A dehydrated mixture containing the same ingredients may be used provided that, when constituted as directed in the labeling, it yields a medium comparable to that obtained from the formula given herein.

Add the ingredients in the order listed, carefully dissolving the cystine and tryptophane in the hydrochloric acid before adding the next eight solutions in the resulting solution. Add 100 mL of water, mix, and dissolve the dextrose, sodium acetate, and ascorbic acid. Filter, if necessary, add the polysorbate 80 solution, adjust the solution to a pH between 5.5 and 6.0 with 1 N sodium hydroxide, and add purified water to make 250 mL.

I-Cystine	0.1 g
I-Tryptophane	0.05 g
1 N Hydrochloric Acid	10 mL
Adenine-Guanine-Uracil Solution	5 mL
Xanthine Solution	5 mL
Vitamin Solution I	10 mL
Vitamin Solution II	10 mL
Salt Solution A	5 mL
Salt Solution B	5 mL
Asparagine Solution	5 mL
Acid-hydrolyzed Casein Solution	25 mL
Dextrose, Anhydrous	10 g
Sodium Acetate, Anhydrous	5 g
Ascorbic Acid	1 g
Polysorbate 80 Solution	5 mL

Acid-Hydrolyzed Casein Solution— Prepare as directed under [Calcium Pantothenate Assay](#) 91.

Asparagine Solution— Dissolve 2.0 g of l-asparagine in water to make 200 mL. Store under toluene in a refrigerator.

Adenine—Guanine—Uracil Solution— Prepare as directed under [Calcium Pantothenate Assay](#) 91.

Xanthine Solution— Suspend 0.20 g of xanthine in 30 mL to 40 mL of water, heat to about 70°, add 6.0 mL of 6 N ammonium hydroxide, and stir until the solid is dissolved. Cool, and add water to make 200 mL. Store under toluene in a refrigerator.

Salt Solution A— Dissolve 10 g of monobasic potassium phosphate and 10 g of dibasic potassium phosphate in water to make 200 mL. Add 2 drops of hydrochloric acid, and store under toluene.

Salt Solution B— Dissolve 4.0 g of magnesium sulfate, 0.20 g of sodium chloride, 0.20 g of ferrous sulfate, and 0.20 g of manganese sulfate in water to make 200 mL. Add 2 drops of hydrochloric acid, and store under toluene.

Polysorbate 80 Solution— Dissolve 20 g of polysorbate 80 in alcohol to make 200 mL. Store in a refrigerator.

Vitamin Solution I— Dissolve 10 mg of riboflavin, 10 mg of thiamine hydrochloride, 100 µg of biotin, and 20 mg of niacin in 0.02 N glacial acetic acid to make 400 mL. Store, protected from light, under toluene in a refrigerator.

Vitamin Solution II— Dissolve 20 mg of para-aminobenzoic acid, 10 mg of calcium pantothenate, 40 mg of pyridoxine hydrochloride, 40 mg of pyridoxal hydrochloride, 8 mg of pyridoxamine dihydrochloride, and 2 mg of folic acid in dilute neutralized alcohol (1 in 4) to make 400 mL. Store, protected from light, in a refrigerator.

Tomato Juice Preparation— Centrifuge commercially canned tomato juice so that most of the pulp is removed. Suspend about 5 g per L of analytical filter-aid in the supernatant, and filter, with the aid of reduced pressure, through a layer of the filter-aid. Repeat, if necessary, until a clear, straw-colored filtrate is obtained. Store under toluene in a refrigerator.

Culture Medium— [note—A dehydrated mixture containing the same ingredients may be used provided that, when constituted as directed in the labeling, it yields a medium equivalent to that obtained from the formula given herein.] Dissolve 0.75 g of water-soluble yeast extract, 0.75 g of dried peptone, 1.0 g of anhydrous dextrose, and 0.20 g of potassium biphosphate in 60 mL to 70 mL of water. Add 10 mL of Tomato Juice Preparation and 1 mL of Polysorbate 80 Solution. Adjust the solution with 1 N sodium hydroxide to a pH of 6.8, and add water to make 100 mL. Place 10-mL portions of the solution in test tubes, and plug with cotton. Sterilize the tubes and contents in an autoclave at 121° for 15 minutes. Cool as rapidly as possible to avoid color formation resulting from overheating the medium.

Suspension Medium— Dilute a measured volume of Basal Medium Stock Solution with an equal volume of water. Place 10-mL portions of the diluted medium in test tubes. Sterilize, and cool as directed above for the Culture Medium.

Stock Culture of *Lactobacillus leichmannii*— To 100 mL of Culture Medium add 1.0 g to 1.5 g of agar, and heat the mixture, with stirring, on a steam bath, until the agar dissolves. Place approximately 10-mL portions of the hot solution in test tubes, cover the tubes suitably, sterilize at 121° for 15 minutes in an autoclave (exhaust line temperature), and allow the

uses to cool in an upright position. Inoculate three or more of the tubes, by stab transfer of a pure culture of *Lactobacillus leichmannii*.\* (Before first using a fresh culture in this assay, make not fewer than 10 successive transfers of the culture in a 2-week period.) Incubate 16 to 24 hours at any selected temperature between 30° and 40° but held constant to within  $\pm 0.5^{\circ}$ , and finally store in a refrigerator.

Prepare fresh stab cultures at least three times each week, and do not use them for preparing the inoculum if more than 4 days old. The activity of the microorganism can be increased by daily or twice-daily transfer of the stab culture, to the point where definite turbidity in the liquid inoculum can be observed 2 to 4 hours after inoculation. A slow-growing culture seldom gives a suitable response curve, and may lead to erratic results.

**Inoculum**— [note—A frozen suspension of *Lactobacillus leichmannii* may be used as the stock culture, provided it yields an inoculum comparable to a fresh culture.] Make a transfer of cells from the Stock Culture of *Lactobacillus leichmannii* to 2 sterile tubes containing 10 mL of the Culture Medium each. Incubate these cultures for 16 to 24 hours at any selected temperature between 30° and 40° but held constant to within  $\pm 0.5^{\circ}$ . Under aseptic conditions, centrifuge the cultures, and decant the supernatant. Suspend the cells from the culture in 5 mL of sterile Suspension Medium, and combine. Using sterile Suspension Medium, adjust the volume so that a 1 in 20 dilution in saline TS produces 70% transmittance when read on a suitable spectrophotometer that has been set at a wavelength of 530 nm, equipped with a 10-mm cell, and read against saline TS set at 100% transmittance. Prepare a 1 in 400 dilution of the adjusted suspension using Basal Medium Stock Solution, and use it for the test inoculum. (This dilution may be altered, when necessary, to obtain the desired test response.)

**Calibration of Spectrophotometer**— Check the wavelength of the spectrophotometer periodically, using a standard wavelength cell or other suitable device. Before reading any tests, calibrate the spectrophotometer for 0% and 100% transmittance, using water and with the wavelength set at 530 nm.

**Procedure**— Cleanse meticulously by suitable means, followed preferably by heating at 250° for 2 hours, hard-glass test tubes, about 20 mm  $\times$  150 mm in size, and other necessary glassware because of the high sensitivity of the test organism to minute amounts of vitamin B12 activity and to traces of many cleansing agents.

To test tubes add, in duplicate, 1.0 mL, 1.5 mL, 2.0 mL, 3.0 mL, 4.0 mL, and 5.0 mL, respectively, of the Standard Cyanocobalamin Solution. To each of these tubes and to four similar empty tubes add 5.0 mL of Basal Medium Stock Solution and water to make 10 mL.

To similar test tubes add, in duplicate, respectively, 1.0 mL, 1.5 mL, 2.0 mL, 3.0 mL, and 4.0 mL of the Assay Preparation. To each tube add 5.0 mL of Basal Medium Stock Solution and water to make 10 mL. Place one complete set of standard and assay tubes together in one tube rack and the duplicate set in a second rack or section of a rack, preferably in random order.

Cover the tubes suitably to prevent bacterial contamination, and sterilize the tubes and contents in an autoclave at 121° for 5 minutes, arranging to reach this temperature in not more than 10 minutes by preheating the autoclave, if necessary. Cool as rapidly as practicable to avoid color formation resulting from overheating the medium. Take precautions to maintain uniformity of sterilizing and cooling conditions throughout the assay, since packing tubes too closely in the autoclave, or overloading it, may cause variation in the heating rate.

Aseptically add 0.5 mL of Inoculum to each tube so prepared, except two of the four containing no Standard Cyanocobalamin Solution (the uninoculated blanks). Incubate the tubes at a temperature between 30° and 40° held constant to within  $\pm 0.5^{\circ}$ , for 16 to 24 hours.

Terminate growth by heating to a temperature not lower than 80° for 5 minutes. Cool to room temperature. After agitating its contents, place the container in a spectrophotometer that has been set at a wavelength of 530 nm, and read the transmittance when a steady state is reached. This steady state is observed a few seconds after agitation when the reading remains constant for 30 seconds or more. Allow approximately the same time interval for the reading on each tube.

With the transmittance set at 100% for the uninoculated blank, read the transmittance of the inoculated blank. If the difference is greater than 5% or if there is evidence of contamination with a foreign microorganism, disregard the results of the assay.

With the transmittance set at 100% for the uninoculated blank, read the transmittance of each of the remaining tubes. Disregard the results of the assay if the slope of the standard curve indicates a problem with sensitivity.

**Calculation**— Prepare a standard concentration-response curve by the following procedure. Test for and replace any aberrant individual transmittances. For each level of the standard, calculate the response from the sum of the duplicate values of the transmittances ( $\Sigma$ ) as the difference,  $y = 2.00 - \Sigma$ . Plot this response on the ordinate of cross-section paper against the logarithm of the mL of Standard Cyanocobalamin Solution per tube on the abscissa, using for the ordinate either an arithmetic or a logarithmic scale, whichever gives the better approximation to a straight line. Draw the straight line or smooth curve that best fits the plotted points.

Calculate the response,  $y$ , adding together the two transmittances for each level of the Assay Preparation. Read from the standard curve the logarithm of the volume of the Standard Preparation corresponding to each of those values of  $y$  that falls within the range of the lowest and highest points plotted for the standard. Subtract from each logarithm so obtained the logarithm of the volume, in mL, of the Assay Preparation to obtain the difference,  $x$ , for each dosage level. Average the values of  $x$  for each of three or more dosage levels to obtain  $x = M'$ , the log-relative potency of the Assay Preparation. Determine the quantity, in  $\mu\text{g}$ , of [USP Cyanocobalamin RS](#) corresponding to the cyanocobalamin in the portion of material taken for assay by the equation  $\text{antilog } M = \text{antilog } (M' + \log R)$ , in which  $R$  is the number of  $\mu\text{g}$  of cyanocobalamin that was assumed to be present in each mg (or capsule or tablet) of the material taken for assay.

**Replication**— Repeat the entire determination at least once, using separately prepared Assay Preparations. If the difference between the two log potencies  $M$  is not greater than 0.08, their mean,  $M$ , is the assayed log-potency of the test material (see Vitamin B12 Activity Assay under [Design and Analysis of Biological Assays](#) (111)). If the two determinations differ by more than 0.08, conduct one or more additional determinations. From the mean of two or more values of  $M$  that do not differ by more than 0.15, compute the mean potency of the preparation under assay.

\* Pure cultures of *Lactobacillus leichmannii* may be obtained as No. 7830 from the American Type Culture Collection, 10801 University Blvd., Manassas, VA 20110.

### 181 IDENTIFICATION—ORGANIC NITROGENOUS BASES

This test is for the identification of tertiary amine compounds.

Dissolve 50 mg of the substance under test, if in bulk, in 25 mL of 0.01 N hydrochloric acid, or shake a quantity of powdered tablets or the contents of capsules equivalent to 50 mg of the substance with 25 mL of 0.01 N hydrochloric acid for 10 minutes. Transfer the liquid to a separator, if necessary filtering it and washing the filter and the residue with several small

solutions of water. In a second separator dissolve 50 mg of the corresponding USP Reference Standard in 25 mL of 0.01 N hydrochloric acid. Treat each solution as follows. Add 2 mL of 1 N sodium hydroxide and 4 mL of carbon disulfide, and shake for 2 minutes. Centrifuge if necessary to clarify the lower phase, and filter it through a dry filter, collecting the filtrate in a small flask provided with a glass stopper.

Determine the absorption spectra of the filtered solutions of both standard and sample without delay, in 1-mm cells between 7  $\mu$ m and 15  $\mu$ m, with a suitable IR spectrophotometer, using carbon disulfide in a matched cell as the blank. The spectrum of the solution prepared from the sample shows all of the significant absorption bands present in the spectrum of the solution prepared from the Reference Standard.

Auxiliary Information—Please [check for your question in the FAQs](#) before contacting USP.

USP32-NF27 Page 127

## 191 IDENTIFICATION TESTS—GENERAL

Under this heading are placed tests that are frequently referred to in the Pharmacopeia for the identification of official articles. [note—The tests are not intended to be applicable to mixtures of substances unless so specified.]

Acetate— When acetic acid or an acetate is warmed with sulfuric acid and alcohol, ethyl acetate, recognizable by its characteristic odor, is evolved. With neutral solutions of acetates, ferric chloride TS produces a deep red color that is destroyed by the addition of mineral acids.

Aluminum— With 6 N ammonium hydroxide, solutions of aluminum salts yield a gelatinous, white precipitate that is insoluble in an excess of 6 N ammonium hydroxide. 1 N sodium hydroxide or sodium sulfide TS produces the same precipitate, which dissolves in an excess of either of these reagents.

Ammonium— Ammonium salts are decomposed by the addition of an excess of 1 N sodium hydroxide, with the evolution of ammonia, recognizable by its odor and by its alkaline effect upon moistened red litmus paper exposed to the vapor. Warming the solution accelerates the decomposition.

Antimony— With hydrogen sulfide, solutions of antimony (III) compounds, strongly acidified with hydrochloric acid, yield an orange precipitate of antimony sulfide that is insoluble in 6 N ammonium hydroxide, but is soluble in [ammonium sulfide TS](#).

Barium— Solutions of barium salts yield a white precipitate with 2 N sulfuric acid. This precipitate is insoluble in hydrochloric acid and in nitric acid. Barium salts impart a yellowish-green color to a nonluminous flame that appears blue when viewed through green glass.

Benzoate— In neutral solutions, benzoates yield a salmon-colored precipitate with [ferric chloride TS](#). In moderately concentrated solutions, benzoates yield a precipitate of benzoic acid upon acidification with 2 N sulfuric acid. This precipitate is readily soluble in ethyl ether.

Bicarbonate— See Carbonate.

Bismuth— When dissolved in a slight excess of nitric acid or hydrochloric acid, bismuth salts yield a white precipitate upon dilution with water. This precipitate is colored brown by hydrogen sulfide, and the resulting compound dissolves in a warm mixture of equal parts of nitric acid and water.

Bisulfite— See Sulfite.

Borate— To 1 mL of a borate solution, acidified with hydrochloric acid to litmus, add 3 or 4 drops of [iodine TS](#) and 3 or 4 drops of polyvinyl alcohol solution (1 in 50); an intense blue color is produced. When a borate is treated with sulfuric acid, methanol is added, and the mixture is ignited, it burns with a green-bordered flame.

Bromide— Solutions of bromides, upon the addition of chlorine TS, dropwise, liberate bromine, which is dissolved by shaking with chloroform, coloring the chloroform red to reddish brown. Silver nitrate TS produces in solutions of bromides a yellowish-white precipitate that is insoluble in nitric acid and is slightly soluble in 6 N ammonium hydroxide.

Calcium— Solutions of calcium salts form insoluble oxalates when treated as follows. To a solution of the calcium salt (1 in 20) add 2 drops of [methyl red TS](#), and neutralize with 6 N ammonium hydroxide. Add 3 N hydrochloric acid, dropwise, until the solution is acid to the indicator. Upon the addition of [ammonium oxalate TS](#), a white precipitate is formed. This precipitate is insoluble in 6 N acetic acid but dissolves in hydrochloric acid. Calcium salts moistened with hydrochloric acid impart a transient yellowish-red color to a nonluminous flame.

Carbonate— Carbonates and bicarbonates effervesce with acids, evolving a colorless gas that, when passed into [calcium hydroxide TS](#), produces a white precipitate immediately. A cold solution (1 in 20) of a soluble carbonate is colored red by phenolphthalein TS, while a similar solution of a bicarbonate remains unchanged or is only slightly colored.

Chlorate— Solutions of chlorates yield no precipitate with [silver nitrate TS](#). The addition of sulfuric acid to this mixture produces a white precipitate that is insoluble in nitric acid, but is soluble in 6 N ammonium hydroxide. Upon ignition, chlorates yield chlorides, recognizable by appropriate tests. When sulfuric acid is added to a dry chlorate, decrepitation occurs, and a greenish yellow-gas is evolved. [Caution—Use only a small amount of chlorate for this test, and exercise extreme caution in performing it.]

Chloride— With [silver nitrate TS](#), solutions of chlorides yield a white, curdy precipitate that is insoluble in nitric acid but is soluble in a slight excess of 6 N ammonium hydroxide. When testing amine (including alkaloidal) hydrochlorides that do not respond to the above test, add one drop of diluted nitric acid and 0.5 mL of [silver nitrate TS](#) to a solution of the substance being examined containing, unless otherwise directed in the monograph, about 2 mg of chloride ion in 2 mL; a white, curdy precipitate is formed. Centrifuge the mixture without delay, and decant the supernatant layer. Wash the precipitate with three 1-mL portions of nitric acid solution (1 in 100), and discard the washings. Add [ammonia TS](#) dropwise to this precipitate. It dissolves readily. When a monograph specifies that an article responds to the test for dry chlorides, mix the solid to be tested with an equal weight of manganese dioxide, moisten with sulfuric acid, and gently heat the mixture; chlorine, which is recognizable by the production of a blue color with moistened starch iodide paper, is evolved.

Citrate— To 15 mL of pyridine add a few mg of a citrate salt, dissolved or suspended in 1 mL of water, and shake. To this mixture add 5 mL of acetic anhydride, and shake: a light red color is produced.

Cobalt— Solutions of cobalt salts (1 in 20) in 3 N hydrochloric acid yield a red precipitate when heated on a steam bath with an equal volume of a hot, freshly prepared solution of 1-nitroso-2-naphthol (1 in 10) in 9 N acetic acid. Solutions of cobalt salts, when saturated with potassium chloride and treated with potassium nitrite and acetic acid, yield a yellow precipitate.

Copper— Solutions of cupric compounds, acidified with hydrochloric acid, deposit a red film of metallic copper upon a bright, untarnished surface of metallic iron. An excess of 6 N ammonium hydroxide, added to a solution of a cupric salt, produces first a bluish precipitate and then a deep blue-colored solution. With [potassium ferrocyanide TS](#), solutions of cupric salts yield a reddish-brown precipitate, insoluble in diluted acids.

Hypophosphite— When strongly heated, hypophosphites evolve spontaneously flammable phosphine. Hypophosphites in solution yield a white precipitate with [mercuric chloride TS](#). This precipitate becomes gray when an excess of hypophosphite is present. Solutions of hypophosphites, acidified with sulfuric acid, and warmed with [cupric sulfate TS](#) yield a red precipitate.

Iodide— Solutions of iodides, upon the addition of chlorine TS, dropwise, liberate iodine, which colors the solution yellow to red. When the solution is shaken with chloroform, the latter is colored violet. The iodine thus liberated gives a blue color with [starch TS](#). Silver nitrate TS produces, in solutions of iodides, a yellow, curdy precipitate that is insoluble in nitric acid and in 6 N ammonium hydroxide.

Iron— Ferrous and ferric compounds in solution yield a black precipitate with [ammonium sulfide TS](#). This precipitate is dissolved by cold 3 N hydrochloric acid with the evolution of hydrogen sulfide.

nitric Salts— Acid solutions of ferric salts yield a dark blue precipitate with [potassium ferrocyanide TS](#). With an excess of 1 N sodium hydroxide, a reddish-brown precipitate is formed. With [ammonium thiocyanate TS](#), solutions of ferric salts produce a deep red color that is not destroyed by dilute mineral acids.

Ferrous Salts— Solutions of ferrous salts yield a dark blue precipitate with [potassium ferricyanide TS](#). This precipitate is insoluble in 3 N hydrochloric acid but is decomposed by 1 N sodium hydroxide. With 1 N sodium hydroxide, solutions of ferrous salts yield a greenish-white precipitate, the color rapidly changing to green and then to brown when shaken.

Lactate— When solutions of lactates are acidified with sulfuric acid, potassium permanganate TS is added, and the mixture is heated, acetaldehyde is evolved. This can be detected by allowing the vapor to come into contact with a filter paper that has been moistened with a freshly prepared mixture of equal volumes of 20% aqueous morpholine and sodium nitroferricyanide TS: a blue color is produced.

Lead— With 2 N sulfuric acid, solutions of lead salts yield a white precipitate that is insoluble in 3 N hydrochloric or 2 N nitric acid, but is soluble in warm 1 N sodium hydroxide and in [ammonium acetate TS](#). With [potassium chromate TS](#), solutions of lead salts, free or nearly free from mineral acids, yield a yellow precipitate that is insoluble in 6 N acetic acid but is soluble in 1 N sodium hydroxide.

Lithium— With [sodium carbonate TS](#), moderately concentrated solutions of lithium salts, made alkaline with sodium hydroxide, yield a white precipitate on boiling. The precipitate is soluble in [ammonium chloride TS](#). Lithium salts moistened with hydrochloric acid impart an intense crimson color to a nonluminous flame. Solutions of lithium salts are not precipitated by 2 N sulfuric acid or soluble sulfates (distinction from strontium).

Magnesium— Solutions of magnesium salts in the presence of ammonium chloride yield no more than a slightly hazy precipitate when neutralized with [ammonium carbonate TS](#), but on the subsequent addition of [dibasic sodium phosphate TS](#), a white, crystalline precipitate, which is insoluble in 6 N ammonium hydroxide, is formed.

Manganese— With [ammonium sulfide TS](#), solutions of manganous salts yield a salmon-colored precipitate that dissolves in acetic acid.

Mercury— When applied to bright copper foil, solutions of mercury salts, free from an excess of nitric acid, yield a deposit that upon rubbing, becomes bright and silvery in appearance. With hydrogen sulfide, solutions of mercury compounds yield a black precipitate that is insoluble in [ammonium sulfide TS](#) and in boiling 2 N nitric acid.

Mercuric Salts— Solutions of mercuric salts yield a yellow precipitate with 1 N sodium hydroxide. They yield also, in neutral solutions with [potassium iodide TS](#), a scarlet precipitate that is very soluble in an excess of the reagent.

Mercurous Salts— Mercurous compounds are decomposed by 1 N sodium hydroxide, producing a black color. With hydrochloric acid, solutions of mercurous salts yield a white precipitate that is blackened by 6 N ammonium hydroxide. With [potassium iodide TS](#), a yellow precipitate, that may become green upon standing, is formed.

Nitrate— When a solution of a nitrate is mixed with an equal volume of sulfuric acid, the mixture is cooled, and a solution of ferrous sulfate is superimposed, a brown color is produced at the junction of the two liquids. When a nitrate is heated with sulfuric acid and metallic copper, brownish-red fumes are evolved. Nitrates do not decolorize acidified potassium permanganate TS (distinction from nitrites).

Nitrite— When treated with dilute mineral acids or with 6 N acetic acid, nitrites evolve brownish-red fumes. The solution colors starch-iodide paper blue.

Oxalate— Neutral and alkaline solutions of oxalates yield a white precipitate with [calcium chloride TS](#). This precipitate is insoluble in 6 N acetic acid but is dissolved by hydrochloric acid. Hot acidified solutions of oxalates decolorize potassium permanganate TS.

Permanganate— Solutions of permanganates acidified with sulfuric acid are decolorized by hydrogen peroxide TS and by sodium bisulfite TS, in the cold, and by oxalic acid TS, in hot solution.

Peroxide— Solutions of peroxides slightly acidified with sulfuric acid yield a deep blue color upon the addition of [potassium dichromate TS](#). On shaking the mixture with an equal volume of ethyl ether and allowing the liquids to separate, the blue color is found in the ethyl ether layer.

Phosphate— [note—Where the monograph specifies the identification test for Phosphate, use the tests for orthophosphates, unless the instructions specify the use of the pyrophosphate tests or indicate that the product is to be ignited before performing the test.] With [silver nitrate TS](#), neutral solutions of orthophosphates yield a yellow precipitate that is soluble in 2 N nitric acid and in 6 N ammonium hydroxide. With [ammonium molybdate TS](#), acidified solutions of orthophosphates yield a yellow precipitate that is soluble in 6 N ammonium hydroxide. This precipitate may be slow to form. With silver nitrate TS, pyrophosphates obtained by ignition yield a white precipitate that is soluble in 2 N nitric acid and in 6 N ammonium hydroxide. With [ammonium molybdate TS](#), a yellow precipitate that is soluble in 6 N ammonium hydroxide is formed.

Potassium— Potassium compounds impart a violet color to a nonluminous flame, but the presence of small quantities of sodium masks the color unless the yellow color produced by sodium is screened out by viewing through a blue filter that blocks emission at 589 nm (sodium) but is transparent to emission at 404 nm (potassium). Traditionally, cobalt glass has been used, but other suitable filters are commercially available. In neutral, concentrated or moderately concentrated solutions of potassium salts (depending upon the solubility and the potassium content), sodium bitartrate TS produces a white crystalline precipitate that is soluble in 6 N ammonium hydroxide and in solutions of alkali hydroxides and carbonates. The formation of the precipitate, which is usually slow, is accelerated by stirring or rubbing the inside of the test tube with a glass rod. The addition of a small amount of glacial acetic acid or alcohol also promotes the precipitation.

Salicylate— In moderately dilute solutions of salicylates, ferric chloride TS produces a violet color. The addition of acids to moderately concentrated solutions of salicylates produces a white, crystalline precipitate of salicylic acid that melts between 158° and 161°.

Silver— With hydrochloric acid, solutions of silver salts yield a white, curdy precipitate that is insoluble in nitric acid, but is readily soluble in 6 N ammonium hydroxide. A solution of a silver salt to which 6 N ammonium hydroxide and a small quantity of [formaldehyde TS](#) are added deposits, upon warming, a mirror of metallic silver upon the sides of the container.

Sodium— Unless otherwise specified in an individual monograph, prepare a solution to contain 0.1 g of the sodium compound in 2 mL of water. Add 2 mL of 15% potassium carbonate, and heat to boiling. No precipitate is formed. Add 4 mL of [potassium pyroantimonate TS](#), and heat to boiling. Allow to cool in ice water and, if necessary, rub the inside of the test tube with a glass rod. A dense precipitate is formed. Sodium compounds impart an intense yellow color to a nonluminous flame.

Sulfate— With [barium chloride TS](#), solutions of sulfates yield a white precipitate that is insoluble in hydrochloric acid and in nitric acid. With [lead acetate TS](#), neutral solutions of sulfates yield a white precipitate that is soluble in [ammonium acetate TS](#). Hydrochloric acid produces no precipitate when added to solutions of sulfates (distinction from thiosulfates).

Sulfite— When treated with 3 N hydrochloric acid, sulfites and bisulfites yield sulfur dioxide, which blackens filter paper moistened with [mercurous nitrate TS](#).

Tartrate— Dissolve a few mg of a tartrate salt in 2 drops of sodium metaperiodate solution (1 in 20). Add a drop of 1 N sulfuric acid, and after 5 minutes add a few drops of sulfuric acid followed by a few drops of fuchsin-sulfurous acid TS: a reddish-pink color is produced within 15 minutes.

Thiocyanate— With [ferric chloride TS](#), solutions of thiocyanates yield a red color that is not destroyed by moderately concentrated mineral acids.

Thiosulfate— With hydrochloric acid, solutions of thiosulfates yield a white precipitate that soon turns yellow, and sulfur dioxide, which blackens filter paper moistened with [mercurous nitrate TS](#). The addition of [ferric chloride TS](#) to solutions of thiosulfates produces a dark violet color that quickly disappears.

Zinc— In the presence of sodium acetate, solutions of zinc salts yield a white precipitate with hydrogen sulfide. This precipitate is insoluble in acetic acid, but is dissolved by 3 N hydrochloric acid. Ammonium sulfide TS produces a similar precipitate in neutral and in alkaline solutions. With [potassium ferrocyanide TS](#), zinc salts in solution yield a white precipitate that is insoluble in 3 N hydrochloric acid.

Auxiliary Information— Please [check for your question in the FAQs](#) before contacting USP.

### 193 IDENTIFICATION— TETRACYCLINES

The following chromatographic procedures are provided to confirm the identity of Pharmacopeial drug substances that are of the tetracycline type, such as doxycycline, oxytetracycline, and tetracycline, and to confirm the identity of such compounds in their respective Pharmacopeial dosage forms. Two procedures are provided, one based on paper chromatography (Method I) and the other on thin-layer chromatography (Method II). Method I is to be used unless otherwise directed in the individual monograph.

Standard Solution— Unless otherwise directed in the individual monograph, dissolve the USP Reference Standard for the drug substance being identified in the same solvent and at the same concentration as for the Test Solution.

Test Solution— Prepare as directed in the individual monograph.

#### METHOD I

pH 3.5 Buffer— Dissolve 13.4 g of anhydrous citric acid and 16.3 g of dibasic sodium phosphate in 1000 mL of water, and mix.

Developing Solvent— On the day of use, mix 10 volumes of chloroform, 20 volumes of nitromethane, and 3 volumes of pyridine.

Mixed Test Solution— Mix equal volumes of the Standard Solution and the Test Solution.

Chromatographic Sheet— Draw a spotting line 2.5 cm from one edge of a 20-cm × 20-cm sheet of filter paper (Whatman No. 1, or equivalent). Impregnate the sheet with pH 3.5 Buffer by passing it through a trough filled with pH 3.5 Buffer, and remove the excess solvent by firmly pressing the sheet between nonfluorescent blotting papers.

Procedure— To a suitable chromatographic chamber, prepared for ascending chromatography (see [Chromatography \(621\)](#)) add Developing Solvent to a depth of 0.6 cm. Apply at 1.5-cm intervals 2  $\mu$ L each of the Standard Solution, the Test Solution, and the Mixed Test Solution to the spotting line of the Chromatographic Sheet. Allow the sheet to dry partially, and while still damp place it in the chromatographic chamber with the bottom edge touching the Developing Solvent. When the solvent front has risen about 10 cm, remove the sheet from the chamber, and expose the sheet to ammonia vapor. Examine the chromatogram under long-wavelength UV light. Record the positions of the major yellow fluorescent spots: the RF value of the principal spot obtained from the Test Solution and from the Mixed Test Solution corresponds to that obtained from the Standard Solution.

#### METHOD II

Resolution Solution— Unless otherwise directed in the individual monograph, prepare a solution in methanol containing 0.5 mg each of USP Chlortetracycline Hydrochloride RS, USP Doxycycline Hydrate RS, USP Oxytetracycline RS, and USP Tetracycline Hydrochloride RS per mL.

Developing Solvent— Prepare a mixture of 0.5 M oxalic acid, previously adjusted with ammonium hydroxide to a pH of 2.0, acetonitrile, and methanol (80:20:20).

Chromatographic Plate— Use a suitable thin-layer chromatographic plate (see [Thin-layer Chromatography under Chromatography \(621\)](#)) coated with a 0.25-mm layer of octylsilanized chromatographic silica gel mixture. Activate the plate by heating it at 130° for 20 minutes, allow to cool, and use while still warm.

Procedure— Separately apply 1  $\mu$ L each of the Standard Solution, the Test Solution, and the Resolution Solution to the Chromatographic Plate. Allow the spots to dry, and develop the chromatogram in the Developing Solvent until the solvent front has moved about three-fourths of the length of the plate. Remove the plate from the developing chamber, mark the solvent front, and allow to air-dry. Expose the plate to ammonia vapors for 5 minutes, and promptly locate the spots on the plate by viewing under long-wavelength UV light: the chromatogram of the Resolution Solution shows clearly separated spots, and the principal spot obtained from the Test Solution corresponds in RF value, intensity, and appearance to that obtained from the Standard Solution.

Auxiliary Information— Please [check for your question in the FAQs](#) before contacting USP.

USP32-NF27 Page 129

### 197 SPECTROPHOTOMETRIC IDENTIFICATION TESTS

Spectrophotometric tests contribute meaningfully toward the identification of many compendial chemical substances. The test procedures that follow are applicable to substances that absorb IR and/or UV radiation (see [Spectrophotometry and Light-Scattering \(851\)](#)).

The IR absorption spectrum of a substance, compared with that obtained concomitantly for the corresponding USP Reference Standard, provides perhaps the most conclusive evidence of the identity of the substance that can be realized from any single test. The UV absorption spectrum, on the other hand, does not exhibit a high degree of specificity. Conformance with both IR absorption and UV absorption test specifications, as called for in a large proportion of compendial monographs, leaves little doubt, if any, regarding the identity of the specimen under examination.

#### INFRARED ABSORPTION

Six methods are indicated for the preparation of previously dried test specimens and Reference Standards for analysis. The reference [\(197K\)](#) in a monograph signifies that the substance under examination is mixed intimately with potassium bromide. The reference [\(197M\)](#) in a monograph signifies that the substance under examination is finely ground and dispersed in mineral oil. The reference [\(197F\)](#) in a monograph signifies that the substance under examination is suspended neat between suitable (for example, sodium chloride or potassium bromide) plates. The reference [\(197S\)](#) signifies that a solution of designated concentration is prepared in the solvent specified in the individual monograph, and the solution is examined in 0.1-mm cells unless a different cell path length is specified in the individual monograph. The reference [\(197A\)](#) signifies that the substance under examination is intimately in contact with an internal reflection element for attenuated total reflectance (ATR) analysis. The reference [\(197E\)](#) signifies that the substance under examination is pressed as a thin sample against a suitable plate for IR microscopic analysis. The ATR [\(197A\)](#) and the [\(197E\)](#) techniques can be used as alternative methods for [\(197K\)](#), [\(197M\)](#), [\(197F\)](#), and [\(197S\)](#) where testing is performed qualitatively and the Reference Standard spectra are similarly obtained.

Record the spectra of the test specimen and the corresponding USP Reference Standard over the range from about 2.6  $\mu$ m to 15  $\mu$ m (3800 cm<sup>-1</sup> to 650 cm<sup>-1</sup>) unless otherwise specified in the individual monograph. The IR absorption spectrum of the preparation of the test specimen, previously dried under conditions specified for the corresponding Reference Standard unless otherwise specified, or unless the Reference Standard is to be used without drying, exhibits maxima only at the same wavelengths as that of a similar preparation of the corresponding USP Reference Standard.

Differences that may be observed in the spectra so obtained sometimes are attributed to the presence of polymorphs, which are not always acceptable (see Procedure under [Spectrophotometry and Light-Scattering \(851\)](#)). Unless otherwise directed in the individual monograph, therefore, continue as follows. If a difference appears in the IR spectra of the analyte and the standard, dissolve equal portions of the test specimen and the Reference Standard in equal volumes of a suitable solvent, evaporate the solution to dryness in similar containers under identical conditions, and repeat the test on the residues.

## ULTRAVIOLET ABSORPTION

The reference **197U** in a monograph signifies that a test solution and a Standard solution are examined spectrophotometrically, in 1-cm cells, over the spectral range from 200 to 400 nm unless otherwise specified in the individual monograph.

Dissolve a portion of the substance under examination in the designated Medium to obtain a test solution having the concentration specified in the monograph for Solution. Similarly prepare a Standard solution containing the corresponding USP Reference Standard.

Record and compare the spectra concomitantly obtained for the test solution and the Standard solution. Calculate absorptivities and/or absorbance ratios where these criteria are included in an individual monograph. Unless otherwise specified, absorbances indicated for these calculations are those measured at the maximum absorbance at about the wavelength specified in the individual monograph. Where the absorbance is to be measured at about the specified wavelength other than that of maximum absorbance, the abbreviations (min) and (sh) are used to indicate a minimum and shoulder, respectively, in an absorption spectrum. The requirements are met if the UV absorption spectra of the test solution and the Standard solution exhibit maxima and minima at the same wavelengths and absorptivities and/or absorbance ratios are within specified limits.

Auxiliary Information— Please [check for your question in the FAQs](#) before contacting USP.

**201 THIN-LAYER CHROMATOGRAPHIC IDENTIFICATION TEST**

## GENERAL PROCEDURE

The following procedure is applicable as an aid in verifying the identities of many compendial drug substances as such and in their respective dosage forms.

Prepare a test solution as directed in the individual monograph. On a line parallel to and about 2 cm from the edge of a suitable thin-layer chromatographic plate, coated with a 0.25-mm layer of chromatographic silica gel mixture (see [Chromatography \(621\)](#)) apply 10  $\mu$ L of this solution and 10  $\mu$ L of a Standard solution prepared from the USP Reference Standard for the drug substance being identified, in the same solvent and at the same concentration as the test solution, unless otherwise directed in the individual monograph. Allow the spots to dry, and develop the chromatogram in a solvent system consisting of a mixture of chloroform, methanol, and water (180:15:1), unless otherwise directed in the individual monograph, until the solvent front has moved about three-fourths of the length of the plate. Remove the plate from the developing chamber, mark the solvent front, and allow the solvent to evaporate. Unless otherwise directed in the individual monograph, locate the spots on the plate by examination under short-wavelength UV light. The RF value of the principal spot obtained from the test solution corresponds to that obtained from the Standard solution.

## PROCEDURE FOR BACITRACIN, NEOMYCIN, AND POLYMYXIN B

The following thin-layer chromatographic procedure is applicable as an aid in verifying the identities of bacitracin, neomycin, and polymyxin B active ingredients and in dosage forms when present singly and in two- and three-component mixtures. The reference **201BNP** in a monograph signifies that this procedure is intended.

Prepare a Test Solution as follows, unless otherwise directed in the individual monograph.

## Test Solution—

for drug substances— Dissolve a portion of Bacitracin, Bacitracin Zinc, Neomycin Sulfate, or Polymyxin B Sulfate in 0.1 N hydrochloric acid to obtain a solution containing about 500 USP Bacitracin Units per mL, 3.5 mg of neomycin (base) per mL, or 10,000 USP Polymyxin B Units per mL.

for solutions— Where the Solution contains neomycin and polymyxin B, dilute a portion of it with 0.1 N hydrochloric acid to obtain a solution containing the equivalent of about 3.5 mg of neomycin (base) per mL. Where the Solution contains polymyxin B but not neomycin, dilute a portion of it with 0.1 N hydrochloric acid to obtain a solution containing about 10,000 USP Polymyxin B Units per mL.

for creams, lotions, and ointments— Where the Cream, Lotion, or Ointment contains Bacitracin or Bacitracin Zinc, transfer a portion of it equivalent to about 500 USP Bacitracin Units, to a 15-mL centrifuge tube. Where the Cream, Lotion, or Ointment contains neomycin, but not Bacitracin or Bacitracin Zinc, transfer a portion of it equivalent to about 3.5 mg of neomycin (base) per mL to a 15-mL centrifuge tube. Add 4 mL of chloroform to the centrifuge tube, and shake well to disperse the Cream, Lotion, or Ointment. Add 1 mL of 0.1 N hydrochloric acid, vortex for 4 minutes, centrifuge, and use the clear supernatant.

note—The Modified Test Solution as described below in the Modified Procedure may be used in lieu of the Test Solution.

Standard Bacitracin Solution— Dissolve a portion of [USP Bacitracin Zinc RS](#) in 0.1 N hydrochloric acid to obtain a solution containing 500 USP Bacitracin Units per mL.

Standard Neomycin Solution— Dissolve a portion of [USP Neomycin Sulfate RS](#) in 0.1 N hydrochloric acid to obtain a solution containing the equivalent of 3.5 mg of neomycin (base) per mL.

Standard Polymyxin B Solution— Dissolve a portion of [USP Polymyxin B Sulfate RS](#) in 0.1 N hydrochloric acid to obtain a solution containing 10,000 USP Polymyxin B Units per mL. Where the article under test also contains Bacitracin or Bacitracin Zinc, dissolve a portion of USP Polymyxin B Sulfate RS in 0.1 N hydrochloric acid to obtain a solution containing 500J USP Polymyxin B Units per mL, J being the ratio of the labeled amount of USP Polymyxin B Units to the labeled amount of USP Bacitracin Units in each g of Cream, Lotion, or Ointment.

Developing Solvent Solution— Prepare a mixture of methanol, isopropyl alcohol, methylene chloride, ammonium hydroxide, and water (4:2:2:1.5).

Procedure— Apply 10  $\mu$ L of the Test Solution and each of the relevant Standard Solutions to a suitable thin-layer chromatographic plate (see [Chromatography \(621\)](#)) coated with a 0.25-mm layer of chromatographic silica gel. Place the plate in a presaturated chromatographic chamber, and develop the chromatogram with the Developing Solvent System until the solvent front has moved about three-fourths of the length of the plate. Remove the plate from the chamber, and dry at 105° for 10 minutes. Spray the plate with a 0.2% solution of ninhydrin in butyl alcohol, and heat at 105° for 5 minutes. The RF value of each principal spot in the chromatogram of the Test Solution corresponds to that of the principal spot in the chromatogram obtained from each relevant Standard Solution as appropriate for the labeled active ingredient or ingredients specified on the label. If the chromatogram of the Test Solution yields excessive streaking, proceed as directed for Modified Procedure.

Modified Procedure— Transfer the Test Solution to a 15-mL centrifuge tube, add 10 mL of saturated aqueous picric acid solution (1.2%, w/v), vortex for 1 minute, centrifuge for 10 minutes, and discard the supernatant. Wash the residue with 1-mL portions of water until no yellow color is observed in the washing. Discard the washings, and dry the residue under stream of nitrogen at 50°. Dissolve the residue in 1 mL of acetone, add 1 mL of a freshly prepared solution of sulfuric acid in acetone (1 in 100), shake, centrifuge for 5 minutes, and discard the supernatant. Rinse the residue with 1 mL of acetone, centrifuge briefly, and discard the washing. Repeat the washing until no yellow color is observed. Dry the residue under a stream of nitrogen at 50°. Dissolve the residue in 0.5 mL of 0.1 N hydrochloric acid (Modified Test Solution). Repeat the Procedure using this Modified Test Solution instead of the Test Solution. The RF value of each principal spot in the chromatogram of the Modified Test Solution corresponds to that of the principal spot in the chromatogram obtained from each relevant Standard Solution as appropriate for the active ingredient or ingredients specified on the label.

Auxiliary Information— Please [check for your question in the FAQs](#) before contacting USP.

## 206 ALUMINUM

This procedure is provided to demonstrate that the content of aluminum (Al) does not exceed the limit given in the individual monograph of a substance labeled as intended for use in hemodialysis. [note—The Standard Preparations and the Test Preparation may be modified, if necessary, to obtain solutions of suitable concentrations adaptable to the linear or working range of the instrument.]

Nitric Acid Diluent— Transfer 40 mL of nitric acid to a 1000-mL volumetric flask, and dilute with water to volume.

Standard Preparations— Treat some aluminum wire with 6 N hydrochloric acid at 80° for a few minutes. Dissolve about 100 mg of the treated wire, accurately weighed, in a mixture of 10 mL of hydrochloric acid and 2 mL of nitric acid by heating at about 80° for approximately 30 minutes. Continue heating until the volume is reduced to about 4 mL. Cool to room temperature, and add 4 mL of water. Evaporate to about 2 mL by heating. Cool, and transfer this solution, with the aid of water, to a 100-mL volumetric flask, dilute with water to volume, and mix. Transfer 10.0 mL of this solution to a second 100-mL volumetric flask, dilute with water to volume, and mix. Transfer 1.0 mL of this solution to a third 100-mL volumetric flask, dilute with water to volume, and mix. The concentration of aluminum in this Standard Preparation is about 1.0 µg per mL. If a more diluted Standard Preparation is required, transfer 1.0-, 2.0-, and 4.0-mL portions of this solution to separate 100-mL volumetric flasks, dilute with Nitric Acid Diluent to volume, and mix. These solutions contain 0.01, 0.02, and 0.04 µg of Al per mL, respectively.

Test Preparation— Unless otherwise directed in the monograph, transfer an accurately weighed amount (in g) of the test substance, as specified in the monograph, to a 100-mL plastic volumetric flask, add 50 mL of water, and sonicate for 30 minutes. Add 4 mL of nitric acid, dilute with water to volume, and mix.

Procedure— Determine the absorbances of the Standard Preparations and the Test Preparation at the aluminum emission line at 309.3 nm with a suitable atomic absorption spectrophotometer (see [Spectrophotometry and Light-Scattering \( 851 \)](#)) equipped with an aluminum hollow-cathode lamp and a flameless electrically heated furnace, using the Nitric Acid Diluent as the blank. Plot the absorbances of the Standard Preparations versus the content of Al, in µg per mL, drawing a straight line best fitting the three points. From the graph so obtained, determine the quantity, in µg, of Al in each mL of the Test Preparation. Calculate the amount of Al in the specimen taken, in µg per g, by multiplying this value by 100/W, where W is the weight, in g, of the substance taken to prepare the Test Preparation.

Auxiliary Information— Please [check for your question in the FAQs](#) before contacting USP.

USP32-NF27 Page 132

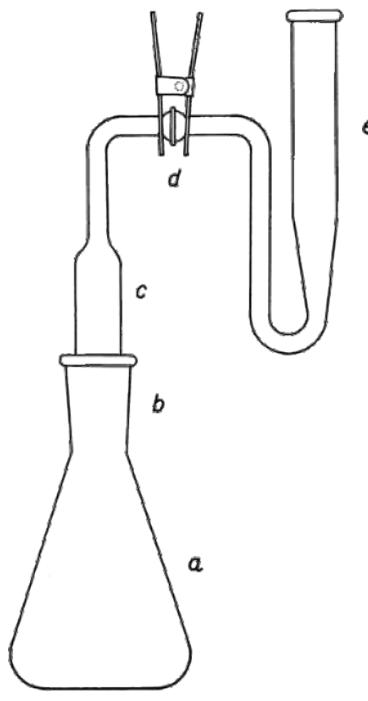

## 211 ARSENIC

This procedure is designed to determine the presence of trace amounts of arsenic (As) by converting the arsenic in a substance under test to arsine, which is then passed through a solution of silver diethyldithiocarbamate to form a red complex. The red color so produced is compared, either visually or spectrophotometrically, to the color produced similarly in a control containing an amount of arsenic equivalent to the limit given in the individual monograph. Limits are stated in terms of arsenic (As). The content of arsenic does not exceed the limit given in the individual monograph.

Two methods are provided, the methods differing only in the preliminary treatment of the test substance and the standard. Generally, Method I is used for inorganic materials, while Method II is used for organic materials.

## Apparatus—

The apparatus (see [illustration](#)) consists of an arsine generator (a) fitted with a scrubber unit (c) and an absorber tube (e) with standard-taper or ground glass ball-and-socket joints (b and d) between the units. However, any other suitable apparatus, embodying the principle of the assembly described and illustrated, may be used.

Arsenic Test Apparatus

**Arsenic Trioxide Stock Solution**— Dissolve 132.0 mg of arsenic trioxide, previously dried at  $105^{\circ}$  for 1 hour and accurately weighed, in 5 mL of sodium hydroxide solution (1 in 5) in a 1000-mL volumetric flask. Neutralize the solution with 2 N sulfuric acid, add 10 mL more of 2 N sulfuric acid, then add recently boiled and cooled water to volume, and mix.

**Standard Arsenic Solution**— Transfer 10.0 mL of Arsenic Trioxide Stock Solution to a 1000-mL volumetric flask, add 10 mL of 2 N sulfuric acid, then add recently boiled and cooled water to volume, and mix. Each mL of Standard Arsenic Solution contains the equivalent of 1  $\mu$ g of arsenic (As). Keep this solution in an all-glass container, and use within 3 days.

#### METHOD I

**Standard Preparation**— Pipet 3.0 mL of Standard Arsenic Solution into a generator flask, and dilute with water to 35 mL.

**Test Preparation**— Unless otherwise directed in the individual monograph, transfer to the generator flask the quantity, in g, of the test substance calculated by the formula:

$$3.0/L$$

in which L is the arsenic limit in ppm, dissolve in water, and dilute with water to 35 mL.

**Procedure**— Treat the Standard Preparation and the Test Preparation similarly as follows. Add 20 mL of 7 N sulfuric acid, 2 mL of [potassium iodide TS](#), 0.5 mL of stronger acid stannous chloride TS, and 1 mL of isopropyl alcohol, and mix. Allow to stand at room temperature for 30 minutes. Pack the scrubber tube (c) with two pledgets of cotton that have been soaked in saturated lead acetate solution, freed from excess solution by expression, and dried in vacuum at room temperature, leaving a 2-mm space between the two pledgets. Lubricate the joints (b and d) with a suitable stopcock grease designed for use with organic solvents, and connect the scrubber unit to the absorber tube (e). Transfer 3.0 mL of [silver diethyldithiocarbamate TS](#) to the absorber tube. Add 3.0 g of granular zinc (No. 20 mesh) to the mixture in the flask, immediately connect the assembled scrubber unit, and allow the evolution of hydrogen and the color development to proceed at room temperature for 45 minutes, swirling the flask gently at 10-minute intervals. Disconnect the absorber tube from the generator and scrubber units, and transfer the absorbing solution to a 1-cm absorption cell. Any red color produced by the Test Preparation does not exceed that produced by the Standard Preparation. If necessary or desirable, determine the absorbance at the wavelength of maximum absorbance between 535 and 540 nm, with a suitable spectrophotometer or colorimeter, using [silver diethyldithiocarbamate TS](#) as the blank.

**Interfering Chemicals**— Metals or salts of metals, such as chromium, cobalt, copper, mercury, molybdenum, nickel, palladium, and silver, may interfere with the evolution of arsine. Antimony, which forms stibine, produces a positive interference in the color development with [silver diethyldithiocarbamate TS](#); when the presence of antimony is suspected, the red colors produced in the two silver diethyldithiocarbamate solutions may be compared at the wavelength of maximum absorbance between 535 and 540 nm, with a suitable colorimeter, since at this wavelength the interference due to stibine is negligible.

#### METHOD II

notes—

(1) Caution—Some substances may react with explosive violence when digested with hydrogen peroxide. Exercise safety precautions at all times.

(2) If halogen-containing compounds are present, use a lower temperature while heating the test specimen with sulfuric acid, avoid boiling the mixture, and add the hydrogen peroxide with caution, before charring begins, to prevent loss of trivalent arsenic.

(3) If the test substance reacts too rapidly and begins charring with 5 mL of sulfuric acid before heating, use instead 10 mL of cooled dilute sulfuric acid (1 in 2), and add a few drops of the hydrogen peroxide before heating.

**Standard Preparation**— Pipet 3.0 mL of Standard Arsenic Solution into a generator flask, add 2 mL of sulfuric acid, mix, and add the total amount of 30 percent hydrogen peroxide used in preparing the Test Preparation. Heat the mixture to strong fuming, cool, add cautiously 10 mL of water, and again heat to strong fumes. Repeat this procedure with another 10 mL of water to remove any traces of hydrogen peroxide. Cool, and dilute with water to 35 mL.

**Test Preparation**— Unless otherwise directed in the individual monograph, transfer to a generator flask the quantity, in g, of the test substance calculated by the formula:

$$3.0 / L$$

in which L is the arsenic limit in ppm. Add 5 mL of sulfuric acid and a few glass beads, and digest in a fume hood, preferably on a hot plate and at a temperature not exceeding  $120^{\circ}$ , until charring begins. (Additional sulfuric acid may be necessary to wet some specimens completely, but the total volume added should not exceed 10 mL.) Cautiously add, dropwise, 30 percent hydrogen peroxide, allowing the reaction to subside and again heating between drops. Add the first few drops very slowly with sufficient mixing, in order to prevent a rapid reaction. Discontinue heating if foaming becomes excessive. When the reaction has abated, heat cautiously, rotating the flask occasionally to prevent the specimen from caking on glass exposed to the heating unit. Maintain oxidizing conditions at all times during the digestion by adding small quantities of the hydrogen peroxide solution whenever the mixture

turns brown or darkens. Continue the digestion until the organic matter is destroyed, gradually raising the temperature of the hot plate until fumes of sulfur trioxide are copiously evolved, and the solution becomes colorless or retains only a light straw color. Cool, add cautiously 10 mL of water, mix, and again evaporate to strong fuming, repeating this procedure to remove any trace of hydrogen peroxide. Cool, add cautiously 10 mL of water, wash the sides of the flask with a few mL of water, and dilute with water to 35 mL.

Procedure— Proceed as directed for Procedure under Method I.

Interfering Chemicals— See Interfering Chemicals under Method I.

Auxiliary Information— Please [check for your question in the FAQs](#) before contacting USP.

USP32-NF27 Page 132

### 221 CHLORIDE AND SULFATE

The following limit tests are provided as general procedures for use where limits for chloride and sulfate are specified in the individual monographs.

Perform the tests and the controls in glass cylinders of the same diameter and matched as closely as practicable in other respects (see Visual Comparison under [Spectrophotometry and Light-Scattering](#) 851). Use the same quantities of the same reagents for both the solution under test and the control solution containing the specified volume of chloride or sulfate. If, after acidification, the solution is not perfectly clear, pass it through a filter paper that gives negative tests for chloride and sulfate. Add the precipitant, silver nitrate TS or barium chloride TS as required, to both the test solution and the control solution in immediate sequence.

Where the individual monograph calls for applying the test to a specific volume of a solution of the substance, and the limit for chloride or sulfate corresponds to 0.20 mL or less of 0.020 N hydrochloric acid or sulfuric acid, respectively, apply the test to the solution without further dilution. In such cases maintain the same volume relationships for the control solution as specified for the solution under test. In applying the test to the salts of heavy metals, which normally show an acid reaction, omit the acidification and do not neutralize the solution. Dissolve bismuth salts in a few mL of water and 2 mL of nitric acid before treating with the precipitant.

Chloride— Dissolve the specified quantity of the substance under test in 30 to 40 mL of water, or, where the substance is already in solution, add water to make a total volume of 30 to 40 mL, and, if necessary, neutralize the solution with nitric acid to litmus. Add 1 mL each of nitric acid and of [silver nitrate TS](#) and sufficient water to make 50 mL. Mix, and allow to stand for 5 minutes protected from direct sunlight. Unless otherwise specified in the monograph, compare the turbidity, if any, with that produced in a solution containing the volume of 0.020 N hydrochloric acid specified in the monograph.

Sulfate— Dissolve the specified quantity of the substance under test in 30 to 40 mL of water, or, where the substance is already in solution, add water to make a total volume of 30 to 40 mL, and, if necessary, neutralize the solution with hydrochloric acid to litmus. Add 1 mL of 3 N hydrochloric acid, 3 mL of [barium chloride TS](#), and sufficient water to make 50 mL. Mix, and allow to stand for 10 minutes. Unless otherwise specified in the monograph, compare the turbidity, if any, with that produced in a solution containing the volume of 0.020 N sulfuric acid specified in the monograph.

Auxiliary Information— Please [check for your question in the FAQs](#) before contacting USP.

### 223 DIMETHYLANILINE

The following limit test is provided as a general procedure, when specified in the individual monographs for the gas chromatographic determination in compendial articles of traces of dimethylaniline, a hydrochloric acid scavenger that may have been carried over during processing.

Internal Standard Solution— Unless otherwise specified in the individual monograph, prepare a solution of naphthalene in cyclohexane containing about 50 µg per mL.

Standard Preparation— Unless otherwise specified in the individual monograph, transfer 50.0 mg of N,N-dimethylaniline to a 50-mL volumetric flask, add 25 mL of 1 N hydrochloric acid, swirl to dissolve, dilute with water to volume, and mix. Transfer 5.0 mL of the resulting solution to a 250-mL volumetric flask, dilute with water to volume, and mix. To a suitable centrifuge tube add 1.0 mL of this solution, 5.0 mL of 1 N sodium hydroxide, and 1.0 mL of Internal Standard Solution, shake vigorously for 1 minute, and centrifuge. Use the clear supernatant as the Standard Preparation.

Test Preparation— Unless otherwise specified in the individual monograph, transfer 1.0 g of the substance to be tested to a suitable centrifuge tube, add 5 mL of 1 N sodium hydroxide, swirl to dissolve the specimen, add 1.0 mL of Internal Standard Solution, shake vigorously for 1 minute, and centrifuge. Use the clear supernatant as the Test Preparation.

Chromatographic System (see [Chromatography](#) 621)— The gas chromatograph is equipped with a flame-ionization detector and a 2-mm × 2-m column packed with 3% liquid phase G3 on silanized packing S1A and is maintained at 120°. Nitrogen is used as the carrier gas, flowing at the rate of about 30 mL per minute.

Procedure— Inject equal volumes (within the range of 2 µL to 20 µL) of the Standard Preparation and the Test Preparation into the chromatograph, record the chromatograms, and measure the areas for the major peaks. The ratio of the response of any dimethylaniline peak to the response of the naphthalene peak obtained from the Test Preparation is not greater than that obtained from the Standard Preparation (0.002%).

Auxiliary Information— Please [check for your question in the FAQs](#) before contacting USP.

USP32-NF27 Page 133

### 226 4-EPIANHYDRO-TETRACYCLINE

This chromatographic procedure is provided to demonstrate that the content of 4-epianhydrotetracycline, a degradation product of tetracycline, does not exceed the limit given in the

individual monograph.

EDTA Buffer— Dissolve 37.2 g of edetate disodium in 800 mL of water, adjust with ammonium hydroxide to a pH of 7.8, dilute with water to 1000 mL, and mix.

Support Phase— Add 5 mL of EDTA Buffer to 10 g of acid-washed chromatographic siliceous earth for column chromatography, and mix until the siliceous earth is uniformly moistened.

Test Solution— Prepare as directed in the individual monograph.

Procedure— Prepare a 15-mm  $\times$  170-mm chromatographic tube with a 4-mm  $\times$  50-mm outlet by packing it, in increments, with Support Phase, firmly tamping down each increment, until the tube is filled to a height of about 10 cm. In a beaker, prepare a mixture of 1 g of acid-washed chromatographic siliceous earth for column chromatography and 1 mL of Test Solution. Transfer the mixture to the top of the column. Dry-wash the beaker with Support Phase, and transfer to the column to provide an additional 1-cm layer on top of the mixture containing the Test Solution. Within 30 minutes, pass chloroform through the column, and collect successive fractions of 5.0 mL, 5.0 mL, 10.0 mL, 10.0 mL, and 5.0 mL. Observe the column during elution, and note the appearance of two separate yellow bands. The fraction or fractions containing the first yellow band contain the anhydrotetracyclines. Discard these fractions. The fractions after the first yellow band contain the 4-epianhydrotetracycline. Determine the absorbance of each 4-epianhydrotetracycline fraction at the wavelength of maximum absorbance at about 438 nm, with a suitable spectrophotometer, diluting each fraction, if necessary, with chloroform, and using chloroform as the blank. Calculate the quantity, in mg, of 4-epianhydrotetracycline in each fraction by the formula:

$$AVD/20.08$$

in which A is the absorbance, V is the volume, in mL, of the fraction taken, D is the dilution factor, if the fraction was diluted, and 20.08 is the absorptivity of 4-epianhydrotetracycline at 438 nm. From the sum of the quantities of 4-epianhydrotetracycline found in the fractions, calculate the percentage of 4-epianhydrotetracycline in relation to the tetracycline hydrochloride equivalent contained in the Test Solution.

Auxiliary Information— Please [check for your question in the FAQs](#) before contacting USP.

## 231 HEAVY METALS

This test is provided to demonstrate that the content of metallic impurities that are colored by sulfide ion, under the specified test conditions, does not exceed the Heavy metals limit specified in the individual monograph in percentage (by weight) of lead in the test substance, as determined by concomitant visual comparison (see Visual Comparison in the section Procedure under [Spectrophotometry and Light-Scattering](#) (851)) with a control prepared from a Standard Lead Solution. [note—Substances that typically will respond to this test are lead, mercury, bismuth, arsenic, antimony, tin, cadmium, silver, copper, and molybdenum.]

Determine the amount of heavy metals by Method I, unless otherwise specified in the individual monograph. Method I is used for substances that yield clear, colorless preparations under the specified test conditions. Method II is used for substances that do not yield clear, colorless preparations under the test conditions specified for Method I, or for substances that, by virtue of their complex nature, interfere with the precipitation of metals by sulfide ion, or for fixed and volatile oils. Method III, a wet-digestion method, is used only in those cases where neither Method I nor Method II can be used.

### Special Reagents

Lead Nitrate Stock Solution— Dissolve 159.8 mg of lead nitrate in 100 mL of water to which has been added 1 mL of nitric acid, then dilute with water to 1000 mL. Prepare and store this solution in glass containers free from soluble lead salts.

Standard Lead Solution— On the day of use, dilute 10.0 mL of Lead Nitrate Stock Solution with water to 100.0 mL. Each mL of Standard Lead Solution contains the equivalent of 10  $\mu$ g of lead. A comparison solution prepared on the basis of 100  $\mu$ L of Standard Lead Solution per g of substance being tested contains the equivalent of 1 part of lead per million parts of substance being tested.

### Method I

pH 3.5 Acetate Buffer— Dissolve 25.0 g of ammonium acetate in 25 mL of water, and add 38.0 mL of 6 N hydrochloric acid. Adjust, if necessary, with 6 N ammonium hydroxide or 6 N hydrochloric acid to a pH of 3.5, dilute with water to 100 mL, and mix.

Standard Preparation— Into a 50-mL color-comparison tube pipet 2 mL of Standard Lead Solution (20  $\mu$ g of Pb), and dilute with water to 25 mL. Using a pH meter or short-range pH indicator paper as external indicator, adjust with 1 N acetic acid or 6 N ammonium hydroxide to a pH between 3.0 and 4.0, dilute with water to 40 mL, and mix.

Test Preparation— Into a 50-mL color-comparison tube place 25 mL of the solution prepared for the test as directed in the individual monograph; or, using the designated volume of acid where specified in the individual monograph, dissolve in and dilute with water to 25 mL the quantity, in g, of the substance to be tested, as calculated by the formula:

$$2.0/(1000L)$$

in which L is the Heavy metals limit, as a percentage. Using a pH meter or short-range pH indicator paper as external indicator, adjust with 1 N acetic acid or 6 N ammonium hydroxide to a pH between 3.0 and 4.0, dilute with water to 40 mL, and mix.

Monitor Preparation— Into a third 50-mL color-comparison tube place 25 mL of a solution prepared as directed for Test Preparation, and add 2.0 mL of Standard Lead Solution. Using a pH meter or short-range pH indicator paper as external indicator, adjust with 1 N acetic acid or 6 N ammonium hydroxide to a pH between 3.0 and 4.0, dilute with water to 40 mL, and mix.

Procedure— To each of the three tubes containing the Standard Preparation, the Test Preparation, and the Monitor Preparation, add 2 mL of pH 3.5 Acetate Buffer, then add 1.2 mL of thioacetamide-glycerin base TS, dilute with water to 50 mL, mix, allow to stand for 2 minutes, and view downward over a white surface: the color of the solution from the Test Preparation is not darker than that of the solution from the Standard Preparation, and the color of the solution from the Monitor Preparation is equal to or darker than that of the solution from the Standard Preparation. [note—if the color of the Monitor Preparation is lighter than that of the Standard Preparation, use Method II instead of Method I for the substance being tested.]

### Method II

note—This method does not recover mercury.

pH 3.5 Acetate Buffer— Prepare as directed under Method I.

Standard Preparation— Prepare as directed under Method I.

Test Preparation— Use a quantity, in g, of the substance to be tested as calculated by the formula:

2.0 / (1000L)

in which L is the Heavy metals limit, in percentage. Transfer the weighed quantity of the substance to a suitable crucible, add sufficient sulfuric acid to wet the substance, and carefully ignite at a low temperature until thoroughly charred. (The crucible may be loosely covered with a suitable lid during the charring.) Add to the carbonized mass 2 mL of nitric acid and 5 drops of sulfuric acid, and heat cautiously until white fumes no longer are evolved. Ignite, preferably in a muffle furnace, at 500° to 600°, until the carbon is completely burned off. Cool, add 4 mL of 6 N hydrochloric acid, cover, digest on a steam bath for 15 minutes, uncover, and slowly evaporate on a steam bath to dryness. Moisten the residue with 1 drop of hydrochloric acid, add 10 mL of hot water, and digest for 2 minutes. Add 6 N ammonium hydroxide dropwise until the solution is just alkaline to litmus paper, dilute with water to 25 mL, and adjust with 1 N acetic acid to a pH between 3.0 and 4.0, using short-range pH indicator paper as an external indicator. Filter if necessary, rinse the crucible and the filter with 10 mL of water, combine the filtrate and rinsing in a 50-mL color-comparison tube, dilute with water to 40 mL, and mix.

Procedure— To each of the tubes containing the Standard Preparation and the Test Preparation, add 2 mL of pH 3.5 Acetate Buffer, then add 1.2 mL of thioacetamide–glycerin base TS, dilute with water to 50 mL, mix, allow to stand for 2 minutes, and view downward over a white surface<sup>\*</sup>: the color of the solution from the Test Preparation is not darker than that of the solution from the Standard Preparation.

### Method III

pH 3.5 Acetate Buffer— Prepare as directed under Method I.

Standard Preparation— Transfer a mixture of 8 mL of sulfuric acid and 10 mL of nitric acid to a clean, dry, 100-mL Kjeldahl flask, and add a further volume of nitric acid equal to the incremental volume of nitric acid added to the Test Preparation. Heat the solution to the production of dense, white fumes; cool; cautiously add 10 mL of water; and, if hydrogen peroxide was used in treating the Test Preparation, add a volume of 30 percent hydrogen peroxide equal to that used for the substance being tested. Boil gently to the production of dense, white fumes. Again cool, cautiously add 5 mL of water, mix, and boil gently to the production of dense, white fumes and to a volume of 2 to 3 mL. Cool, dilute cautiously with a few mL of water, add 2.0 mL of Standard Lead Solution (20 µg of Pb), and mix. Transfer to a 50-mL color-comparison tube, rinse the flask with water, adding the rinsing to the tube until the volume is 25 mL, and mix.

Test Preparation— Unless otherwise indicated in the individual monograph, use a quantity, in g, of the substance to be tested as calculated by the formula:

2.0/(1000L)

in which L is the Heavy metals limit, as a percentage.

If the substance is a solid— Transfer the weighed quantity of the test substance to a clean, dry, 100-mL Kjeldahl flask. [note—A 300-mL flask may be used if the reaction foams excessively.] Clamp the flask at an angle of 45°, and add a sufficient quantity of a mixture of 8 mL of sulfuric acid and 10 mL of nitric acid to moisten the substance thoroughly. Warm gently until the reaction commences, allow the reaction to subside, and add portions of the same acid mixture, heating after each addition, until a total of 18 mL of the acid mixture has been added. Increase the amount of heat, and boil gently until the solution darkens. Cool, add 2 mL of nitric acid, and heat again until the solution darkens. Continue the heating, followed by addition of nitric acid until no further darkening occurs, then heat strongly to the production of dense, white fumes. Cool, cautiously add 5 mL of water, boil gently to the production of dense, white fumes, and continue heating until the volume is reduced to a few mL. Cool, cautiously add 5 mL of water, and examine the color of the solution. If the color is yellow, cautiously add 1 mL of 30 percent hydrogen peroxide, and again evaporate to the production of dense, white fumes and a volume of 2 to 3 mL. If the solution is still yellow, repeat the addition of 5 mL of water and the peroxide treatment. Cool, dilute cautiously with a few mL of water, and rinse into a 50-mL color-comparison tube, taking care that the combined volume does not exceed 25 mL.

If the substance is a liquid— Transfer the weighed quantity of the test substance to a clean, dry, 100-mL Kjeldahl flask. [note—A 300-mL flask may be used if the reaction foams excessively.] Clamp the flask at an angle of 45°, and cautiously add a few mL of a mixture of 8 mL of sulfuric acid and 10 mL of nitric acid. Warm gently until the reaction commences, allow the reaction to subside, and proceed as directed for if the substance is a solid, beginning with “add portions of the same acid mixture.”

Monitor Preparation— Proceed with the digestion, using the same amount of sample and the same procedure as directed in the subsection If the substance is a solid in the section Test Preparation, until the step “Cool, dilute cautiously with a few mL of water.” Add 2.0 mL of Lead Standard Solution (20 µg of lead), and mix. Transfer to a 50-mL color comparison tube, rinse the flask with water, adding the rinsing to the tube until the volume is 25 mL, and mix.

Procedure— Treat the Test Preparation, the Standard Preparation, and the Monitor Preparation as follows. Using a pH meter or short-range pH indicator paper as external indicator, adjust the solution to a pH between 3.0 and 4.0 with ammonium hydroxide (a dilute ammonia solution may be used, if desired, as the specified range is approached), dilute with water to 40 mL, and mix.

To each tube add 2 mL of pH 3.5 Acetate Buffer, then add 1.2 mL of thioacetamide–glycerin base TS, dilute with water to 50 mL, mix, allow to stand for 2 minutes, and view downward over a white surface<sup>\*</sup>: the color of the Test Preparation is not darker than that of the Standard Preparation, and the color of the Monitor Preparation is equal to or darker than that of the Standard Preparation.

\* In those countries or jurisdictions where thioacetamide cannot be used, add 10 mL of freshly prepared [hydrogen sulfide TS](#) to each of the tubes, mix, allow to stand for 5 minutes, and view downward over a white surface.

Auxiliary Information— Please [check for your question in the FAQs](#) before contacting USP.

Pharmacopeial Forum: Volume No. 32(1) Page 182

241 IRON

This limit test is provided to demonstrate that the content of iron, in either the ferric or the ferrous form, does not exceed the limit for iron specified in the individual monograph. The determination is made by concomitant visual comparison with a control prepared from a standard iron solution.

### Special Reagents—

STANDARD IRON SOLUTION— Dissolve 863.4 mg of ferric ammonium sulfate [FeNH4(SO4)2·12H2O] in water, add 10 mL of 2 N sulfuric acid, and dilute with water to 100.0 mL. Pipet 10 mL of this solution into a 1000-mL volumetric flask, add 10 mL of 2 N sulfuric acid, dilute with water to volume, and mix. This solution contains the equivalent of 0.01 mg (10 µg) of iron per mL.

AMMONIUM THIOCYANATE SOLUTION— Dissolve 30 g of ammonium thiocyanate in water to make 100 mL.

Standard Preparation— Into a 50-mL color-comparison tube pipet 1 mL of Standard Iron Solution (10 µg of Fe), dilute with water to 45 mL, add 2 mL of hydrochloric acid, and mix.

Test Preparation— Into a 50-mL color comparison tube place the solution prepared for the test as directed in the individual monograph and if necessary dilute with water to 45 mL; or, dissolve in water, and dilute with water to 45 mL the quantity, in g, of the substance to be tested, as calculated by the formula:

1.0 / (1000L)

in which L is the Iron limit in percentage. Add 2 mL of hydrochloric acid, and mix.

Procedure— To each of the tubes containing the Standard Preparation and the Test Preparation add 50 mg of ammonium peroxysulfate crystals and 3 mL of Ammonium Thiocyanate Solution, and mix: the color of the solution from the Test Preparation is not darker than that of the solution from the Standard Preparation.

Auxiliary Information— Please [check for your question in the FAQs](#) before contacting USP.

USP32-NF27 Page 136

### 251 LEAD

The imposition of stringent limits on the amounts of lead that may be present in pharmaceutical products has resulted in the use of two methods, of which the one set forth following depends upon extraction of lead by solutions of dithizone. For determination of the content of heavy metals generally, expressed as a lead equivalent, see [Heavy Metals](#) 231.

Select all reagents for this test to have as low a content of lead as practicable, and store all reagent solutions in containers of borosilicate glass. Rinse thoroughly all glassware with warm dilute nitric acid (1 in 2), followed by water.

#### Special Reagents—

AMMONIA-CYANIDE SOLUTION— Dissolve 2 g of potassium cyanide in 15 mL of ammonium hydroxide, and dilute with water to 100 mL.

AMMONIUM CITRATE SOLUTION— Dissolve 40 g of citric acid in 90 mL of water. Add 2 or 3 drops of phenol red TS, then cautiously add ammonium hydroxide until the solution acquires a reddish color. Remove any lead that may be present by extracting the solution with 20-mL portions of Dithizone Extraction Solution (see below), until the dithizone solution retains its orange-green color.

DILUTED STANDARD LEAD SOLUTION— Dilute an accurately measured volume of Standard Lead Solution (see [Heavy Metals](#) 231) [containing 10 µg of lead per mL], with 9 volumes of dilute nitric acid (1 in 100) to obtain a solution that contains 1 µg of lead per mL.

DITHIZONE EXTRACTION SOLUTION— Dissolve 30 mg of dithizone in 1000 mL of chloroform, and add 5 mL of alcohol. Store the solution in a refrigerator.

Before use, shake a suitable volume of the dithizone extraction solution with about half its volume of dilute nitric acid (1 in 100), discarding the nitric acid.

HYDROXYLAMINE HYDROCHLORIDE SOLUTION— Dissolve 20 g of hydroxylamine hydrochloride in sufficient water to make approximately 65 mL. Transfer to a separator, add 5 drops of [thymol blue TS](#), then add ammonium hydroxide until the solution assumes a yellow color. Add 10 mL of sodium diethylthiocarbamate solution (1 in 25), mix, and allow to stand for 5 minutes. Extract this solution with successive 10- to 15-mL portions of chloroform until a 5-mL portion of the chloroform extract does not assume a yellow color when shaken with [cupric sulfate TS](#). Add 3 N hydrochloric acid until the solution is pink (if necessary, add 1 or 2 drops more of [thymol blue TS](#)), and then dilute with water to 100 mL.

POTASSIUM CYANIDE SOLUTION— Dissolve 50 g of potassium cyanide in sufficient water to make 100 mL. Remove the lead from this solution by extraction with successive portions of Dithizone Extraction Solution, as described under Ammonium Citrate Solution above, then extract any dithizone remaining in the cyanide solution by shaking with chloroform. Finally dilute the cyanide solution with sufficient water so that each 100 mL contains 10 g of potassium cyanide.

STANDARD DITHIZONE SOLUTION— Dissolve 10 mg of dithizone in 1000 mL of chloroform. Keep the solution in a glass-stoppered, lead-free bottle, suitably wrapped to protect it from light, and store in a refrigerator.

Test Preparation— [note—If, in the following preparation, the substance under test reacts too rapidly and begins charring with 5 mL of sulfuric acid before heating, use instead 10 mL of cooled dilute sulfuric acid (1 in 2), and add a few drops of the hydrogen peroxide before heating.] Where the monograph does not specify preparation of a solution, prepare a Test Preparation as follows. [Caution—Exercise safety precautions in this procedure, as some substances may react with explosive violence when digested with hydrogen peroxide.] Transfer 1.0 g of the substance under test to a suitable flask, add 5 mL of sulfuric acid and a few glass beads, and digest on a hot plate in a hood until charring begins. Other suitable means of heating may be substituted. (Add additional sulfuric acid, if necessary, to wet the substance completely, but do not add more than a total of 10 mL.) Add, dropwise and with caution, 30 percent hydrogen peroxide, allowing the reaction to subside and again heating between drops. Add the first few drops very slowly, mix carefully to prevent a rapid reaction, and discontinue heating if foaming becomes excessive. Swirl the solution in the flask to prevent unreacted substance from caking on the walls of the flask. [note—Add peroxide whenever the mixture turns brown or darkens.] Continue the digestion until the substance is completely destroyed, copious fumes of sulfur trioxide are evolved, and the solution is colorless. Cool, cautiously add 10 mL of water, evaporate until sulfur trioxide again is evolved, and cool. Repeat this procedure with another 10 mL of water to remove any traces of hydrogen peroxide. Cautiously dilute with 10 mL of water, and cool.

Procedure— Transfer the Test Preparation, rinsing with 10 mL of water, or the volume of the prepared sample specified in the monograph to a separator, and, unless otherwise directed in the monograph, add 6 mL of Ammonium Citrate Solution and 2 mL of Hydroxylamine Hydrochloride Solution. (For the determination of lead in iron salts use 10 mL of Ammonium Citrate Solution.) Add 2 drops of phenol red TS, and make the solution just alkaline (red in color) by the addition of ammonium hydroxide. Cool the solution if necessary, and add 2 mL of Potassium Cyanide Solution. Immediately extract the solution with 5-mL portions of Dithizone Extraction Solution, draining off each extract into another separator, until the dithizone solution retains its green color. Shake the combined dithizone solutions for 30 seconds with 20 mL of dilute nitric acid (1 in 100), and discard the chloroform layer. Add to the acid solution 5.0 mL of Standard Dithizone Solution and 4 mL of Ammonia-Cyanide Solution, and shake for 30 seconds: the color of the chloroform layer is of no deeper shade of violet than that of a control made with a volume of Diluted Standard Lead Solution equivalent to the amount of lead permitted in the sample under examination, and the same quantities of the same reagents and in the same manner as in the test with the sample.

Auxiliary Information— Please [check for your question in the FAQs](#) before contacting USP.

USP32-NF27 Page 136

### 261 MERCURY

#### Method I

note—Mercuric dithizone is light-sensitive. Perform this test in subdued light.

Reagents—

dithizone stock solution— Dissolve 40 mg of dithizone in 1000 mL of chloroform.

dithizone titrant— Dilute 30.0 mL of Dithizone Stock Solution with chloroform to 100.0 mL. This solution contains approximately 12 mg of dithizone per L.

Mercury stock solution— Transfer 135.4 mg of mercuric chloride to a 100-mL volumetric flask, and dilute with 1 N sulfuric acid to volume. This solution contains the equivalent of 15 mg of Hg in 100 mL.

mercury solution for standardizing dithizone titrant— Transfer 2.0 mL of Mercury Stock Solution to a 100-mL volumetric flask, and dilute with 1 N sulfuric acid to volume. Each mL of this solution contains the equivalent of 20 µg of Hg.

The following solutions are called for in the limit test for mercury that is specified in the monographs on Ferrous Fumarate, Ferrous Sulfate, and Dried Ferrous Sulfate.

hydroxylamine hydrochloride solution— Prepare as directed in the test for [Lead](#) (251).

standard mercury solution— On the day of use, quantitatively dilute 1.0 mL of Mercury Stock Solution with 1 N sulfuric acid to 1000 mL. Each mL of the resulting solution contains the equivalent of 1 µg of mercury.

dithizone extraction solution— Prepare as directed in the test for [Lead](#) (251).

diluted dithizone extraction solution— Just prior to use, dilute 5 mL of Dithizone Extraction Solution with 25 mL of chloroform.

Standardization of Dithizone Titrant— Transfer 1.0 mL of Mercury Solution for Standardizing Dithizone Titrant to a 250-mL separator, and add 100 mL of 1 N sulfuric acid, 90 mL of water, 1 mL of glacial acetic acid, and 10 mL of hydroxylamine hydrochloride solution (1 in 5). Titrate the solution with Dithizone Titrant from a 10-mL microburet, shaking the mixture 20 times after each addition and allowing the chloroform layer to separate, then discarding the chloroform layer. Continue until a final addition of Dithizone Titrant is green in color after shaking. Calculate the quantity, in µg, of Hg equivalent to each mL of Dithizone Titrant by the formula:

$$20 / V$$

in which V is the volume, in mL, of Dithizone Titrant added.

Test Preparation— Transfer about 2 g of the substance under test, accurately weighed, to a glass-stoppered, 250-mL conical flask, add 20 mL of a mixture of equal volumes of nitric acid and sulfuric acid, attach a suitable condenser, reflux the mixture for 1 hour, cool, cautiously dilute with water, and boil until fumes of nitrous acid no longer are noticeable. Cool the solution, cautiously dilute with water, transfer to a 200-mL volumetric flask, dilute with water to volume, mix, and filter.

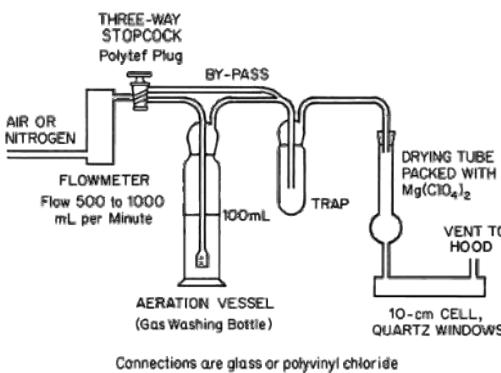

Procedure— Transfer 50.0 mL of Test Preparation to a 250-mL separator, and extract with successive small portions of chloroform until the last chloroform extract remains colorless.

Discard the chloroform extract, and add to the extracted Test Preparation 50 mL of 1 N sulfuric acid, 90 mL of water, 1 mL of glacial acetic acid, and 10 mL of hydroxylamine hydrochloride solution (1 in 5). Proceed as directed under Standardization of Dithizone Titrant, beginning with "Titrate the solution." Calculate the amount of mercury.

#### Method Ia and Method Ib

Mercury Detection Instrument— Use any suitable atomic absorption spectrophotometer equipped with a fast-response recorder and capable of measuring the radiation absorbed by mercury vapors at the mercury resonance line of 253.6 nm. [note—Wash all glassware associated with the test with nitric acid, and rinse thoroughly with water before use.]

Aeration Apparatus— The apparatus (see [accompanying diagram](#)) consists of a flowmeter capable of measuring flow rates from 500 to 1000 mL per minute, connected via a three-way stopcock fitted with a polytef plug to an aeration vessel (250-mL gas washing bottle), followed by a trap, a drying tube packed with magnesium perchlorate, a 10-cm × 25-mm flow-through cell with quartz windows, and terminating with a vent to a fume hood.

#### Mercury Aeration Apparatus

##### Reagents—

Potassium Permanganate Solution— Dissolve 5 g of potassium permanganate in 100 mL of water.

Hydroxylamine Hydrochloride Solution— Dissolve 10 g of hydroxylamine hydrochloride in 100 mL of water.

Stannous Chloride Solution— Dissolve 10 g of SnCl2·2H2O in 20 mL of warm hydrochloric acid, and add 80 mL of water. Prepare fresh each week.

Standard Mercury Solution— Prepare from Mercury Stock Solution as directed under Method I. Each mL of the Standard Mercury Solution contains the equivalent of 1 µg of mercury.

Test Preparation— Unless otherwise directed in the individual monograph, use the quantity, in g, of the test substance calculated by the formula:

$$2.0 / L$$

in which L is the mercury limit, in ppm.

#### Method IIa

Standard Preparation— Pipet 2.0 mL of Standard Mercury Solution into a 100-mL beaker, and add 35 mL of water, 3 mL of sulfuric acid, and 1 mL of potassium permanganate solution. Cover the beaker with a watch glass, boil for a few seconds, and cool.

Test Preparation— Transfer the calculated amount of the test substance to a 100-mL beaker, and add 35 mL of water. Stir, and warm to assist solution, if necessary. Add 2 drops of phenolphthalein TS, and, as necessary, slowly neutralize with constant stirring, using 1 N sodium hydroxide or 1 N sulfuric acid. Add 3 mL of sulfuric acid and 1 mL of Potassium Permanganate Solution. Cover the beaker with a watch glass, boil for a few seconds, and cool.

Procedure— Assemble the Aeration Apparatus as shown in the accompanying diagram, with the aeration vessel and the trap empty, and the stopcock in the bypass position. Connect the apparatus to the absorption cell, and adjust the air or nitrogen flow rate so that, in the following procedure, maximum absorption and reproducibility are obtained without excessive foaming in the test solution. Obtain a smooth baseline reading at 253.6 nm, following the manufacturer's instructions for operating the instrument.

Treat the Standard Preparation and the Test Preparation similarly, as follows. Destroy the excess permanganate by adding Hydroxylamine Hydrochloride Solution, dropwise, until the solution is colorless. Immediately wash the solution into the aeration vessel with water, and dilute with water to 100 mL. Add 2 mL of Stannous Chloride Solution, and immediately

Connect the aeration vessel to the aeration apparatus. Turn the stopcock from the bypass position to the aerating position, and continue the aeration until the absorption peak has been passed and the recorder pen returns to the baseline. Disconnect the aeration vessel from the apparatus, and wash with water after each use. After correcting for any reagent blank, any absorbance produced by the Test Preparation does not exceed that produced by the Standard Preparation.

#### Method IIb

**Caution**—Some substances may react with explosive violence when digested with hydrogen peroxide. Exercise safety precautions at all times.

**Standard Preparation**—Pipet 2.0 mL of Standard Mercury Solution into a 125-mL conical flask, add 3 mL each of nitric acid and sulfuric acid, mix, and add an amount of 30 percent hydrogen peroxide equal to the total amount used in preparing the Test Preparation. Attach a suitable water-cooled condenser with a standard-taper joint to fit the flask, and reflux the mixture in a fume hood for 1 hour. Turn off the water circulating through the condenser, and heat until white fumes appear in the flask. Cool, and cautiously add 10 mL of water through the condenser, while swirling the flask. Again heat until white fumes appear, cool, and add an additional 15 mL of water. Remove the condenser, and rinse the sides of the flask to obtain a volume of 35 mL. Add 1 mL of Potassium Permanganate Solution, boil for a few seconds, and cool.

**Test Preparation**—Transfer the calculated amount of the test substance to a 125-mL conical flask. Add 5 mL each of nitric acid and sulfuric acid and a few glass beads. Attach a suitable water-cooled condenser with a standard-taper joint to fit the flask, and digest in a fume hood, preferably on a hot plate, and at a temperature not exceeding 120°, until charring begins. (If additional sulfuric acid is necessary to wet the specimen completely, add it carefully through the condenser, but do not allow the total volume added to exceed 10 mL.) After the test substance has been decomposed by the acid, cautiously add, dropwise through the condenser, 30 percent hydrogen peroxide, allowing the reaction to subside and again heating between drops (add the first few drops very slowly with sufficient mixing, in order to prevent a rapid reaction; discontinue heating if foaming becomes excessive). When the reaction has abated, heat cautiously, rotating the flask occasionally to prevent the specimen from caking on glass exposed to the heating unit. Maintain oxidizing conditions at all times during the digestion by adding small quantities of the hydrogen peroxide solution whenever the mixture turns brown or darkens. Continue the digestion until the organic matter is destroyed, and then reflux the mixture for 1 hour. Turn off the water circulating through the condenser, and heat until fumes of sulfur trioxide are copiously evolved and the solution becomes colorless or retains only a light straw color. Cool, and cautiously add 10 mL of water through the condenser, while swirling the flask. Again heat until white fumes appear.

Cool, and cautiously add 15 mL of water. Remove the condenser, and rinse the sides of the flask with a few mL of water to obtain a volume of 35 mL. Add 1 mL of Potassium Permanganate Solution, boil for a few seconds, and cool.

**Procedure**—Proceed as directed for Procedure under Method IIa.

**Auxiliary Information**—Please [check for your question in the FAQs](#) before contacting USP.

USP32-NF27 Page 137

#### 271 READILY CARBONIZABLE SUBSTANCES TEST

In tests for readily carbonizable substances, unless otherwise directed, add the specified quantity of the substance, finely powdered if in solid form, in small portions to the comparison container, which is made of colorless glass resistant to the action of sulfuric acid and contains the specified volume of [sulfuric acid TS](#) (see under Test Solutions).

Stir the mixture with a glass rod until solution is complete, allow the solution to stand for 15 minutes, unless otherwise directed, and compare the color of the solution with that of the specified matching fluid in a comparison container, which also is of colorless glass and has the same internal and cross-section dimensions, viewing the fluids transversely against a background of white porcelain or white glass.

When heat is directed in order to effect solution of the substance in the sulfuric acid TS, mix the sample and the acid in a test tube, heat as directed, and transfer the solution to the comparison container for matching with the designated Matching Fluid (see [Color and Achromicity](#) 631).

Special attention is directed to the importance of the concentration of sulfuric acid used in this test. The reagent of the required strength, i.e., 95.0 ± 0.5 percent of H<sub>2</sub>SO<sub>4</sub>, is designated as a "Test Solution."

**Auxiliary Information**—Please [check for your question in the FAQs](#) before contacting USP.

Pharmacopeial Forum: Volume No. 33(6) Page 1258

#### 281 RESIDUE ON IGNITION

Portions of this general chapter have been harmonized with the corresponding texts of the European Pharmacopoeia and the Japanese Pharmacopoeia. The portions that are not harmonized are marked with symbols (◆◆). The harmonized texts of these pharmacopeias are therefore interchangeable, and the methods of the European Pharmacopoeia and/or the Japanese Pharmacopoeia may be used for demonstration of compliance instead of the present United States Pharmacopoeia general chapter. These pharmacopeias have undertaken not to make any unilateral change to this harmonized chapter.

The Residue on Ignition / Sulfated Ash test uses a procedure to measure the amount of residual substance not volatilized from a sample when the sample is ignited in the presence of sulfuric acid according to the procedure described below. This test is usually used for determining the content of inorganic impurities in an organic substance.

**Procedure**—Ignite a suitable crucible (for example, silica, platinum, quartz, or porcelain) at 600 ± 50° for 30 minutes, cool the crucible in a desiccator (silica gel or other suitable desiccant), and weigh it accurately. Weigh accurately ◆1 to 2 g of the substance, or ◆ the amount specified in the individual monograph, in the crucible.

Moisten the sample with a small amount (usually 1 mL) of sulfuric acid, then heat gently at a temperature as low as practicable until the sample is thoroughly charred. Cool; then, ◆unless otherwise directed in the individual monograph, ◆ moisten the residue with a small amount (usually 1 mL) of sulfuric acid; heat gently until white fumes are no longer evolved; and ignite at 600 ± 50°. ◆unless another temperature is specified in the individual monograph, ◆ until the residue is completely incinerated. Ensure that flames are not produced at any time during the procedure. Cool the crucible in a desiccator (silica gel or other suitable desiccant), weigh accurately, and calculate the percentage of residue.

Unless otherwise specified, if the amount of the residue so obtained exceeds the limit specified in the individual monograph, repeat the moistening with sulfuric acid, heating and igniting as before, using a 30-minute ignition period, until two consecutive weighings of the residue do not differ by more than 0.5 mg or until the percentage of residue complies with the limit in the individual monograph.

◆Conduct the ignition in a well-ventilated hood, but protected from air currents, and at as low a temperature as is possible to effect the complete combustion of the carbon. A muffle furnace may be used, if desired, and its use is recommended for the final ignition at 600 ± 50°.

Calibration of the muffle furnace may be carried out using an appropriate digital temperature meter and a working thermocouple probe calibrated against a standard thermocouple

traceable to the National Institute of Standards and Technology.

Verify the accuracy of the measuring and controlling circuitry of the muffle furnace by checking the positions in the furnace at the control set point temperature of intended use. Select positions that reflect the eventual method of use with respect to location of the specimen under test. The tolerance is  $\pm 25^\circ$  at each position measured.♦

USP32-NF27 Page 138

Pharmacopeial Forum: Volume No. 31(5) Page 1526

### 291 SELENIUM

Stock Solution— Dissolve 40.0 mg of metallic selenium in 100 mL of dilute nitric acid (1 in 2) in a 1000-mL volumetric flask, warming gently on a steam bath if necessary to effect solution, add water to volume, and mix. Pipet 5 mL of this solution into a 200-mL volumetric flask, add water to volume, and mix. Each mL of the resulting solution contains the equivalent of 1  $\mu$ g of selenium (Se).

Diaminonaphthalene Solution— Dissolve 100 mg of 2,3-diaminonaphthalene and 500 mg of hydroxylamine hydrochloride in 0.1 N hydrochloric acid to make 100 mL. Prepare this solution fresh on the day of use.

Standard Solution— Pipet 6 mL of Stock Solution into a 150-mL beaker, and add 25 mL of dilute nitric acid (1 in 30) and 25 mL of water.

Test Solution— Clean combustion of the test material is an important factor in conducting the test. For compounds that burn poorly and produce soot, the addition of magnesium oxide usually results in more thorough combustion and reduces soot formation. Where the need to add magnesium oxide has been identified, it is specified in the individual monograph.

Using a 1000-mL combustion flask and using 25 mL of dilute nitric acid (1 in 30) as the absorbing liquid, proceed as directed under [Oxygen Flask Combustion](#) (471), using a test specimen weighing 100 to 200 mg, unless directed otherwise in the individual monograph. Upon completion of the combustion, place a few mL of water in the cup, loosen the stopper, and rinse the stopper, the specimen holder, and the sides of the flask with about 10 mL of water. Transfer the solution with the aid of about 20 mL of water to a 150-mL beaker, and heat gently to the boiling temperature. Boil for 10 minutes, and allow the solution to cool to room temperature.

Procedure— Treat the Standard Solution, the Test Solution, and the reagent blank consisting of 25 mL of dilute nitric acid (1 in 30) and 25 mL of water, concomitantly and in parallel, as follows. Add ammonium hydroxide solution (1 in 2) to adjust to a pH of  $2.0 \pm 0.2$ . Dilute with water to 60 mL, and transfer to a low-actinic separator with the aid of 10 mL of water, adding the 10 mL of rinsings to the separator. Add 200 mg of hydroxylamine hydrochloride, swirl to dissolve, immediately add 5.0 mL of Diaminonaphthalene Solution, insert the stopper, and swirl to mix. Allow the solution to stand at room temperature for 100 minutes. Add 5.0 mL of cyclohexane, shake vigorously for 2 minutes, and allow the layers to separate. Discard the aqueous layer, and centrifuge the cyclohexane extract to remove any dispersed water. Determine the absorbances of the cyclohexane extracts of the Test Solution and the Standard Solution in a 1-cm cell at the wavelength of maximum absorbance at about 380 nm, with a suitable spectrophotometer, using the cyclohexane extract of the reagent blank as the blank, and compare the absorbances: the absorbance of the Test Solution is not greater than that of the Standard Solution where a 200-mg test specimen has been taken, or is not greater than one-half that of the Standard Solution where a 100-mg test specimen has been taken.

Auxiliary Information— Please [check for your question in the FAQs](#) before contacting USP.

### 301 ACID-NEUTRALIZING CAPACITY

note—All tests shall be conducted at a temperature of  $37 \pm 3^\circ$ .

Standardization of pH Meter— Standardize a pH meter using the 0.05 m potassium biphthalate and 0.05 m potassium tetraoxalate standardizing buffers as described under [pH](#) (791).

Magnetic Stirrer— Transfer 100 mL of water to a 250-mL beaker containing a 40- x 10-mm (or other suitable size) magnetic stirring bar that is coated with solid perfluorocarbon and has a spin ring at its center. Adjust the power setting of the magnetic stirrer to produce a stirring rate of  $300 \pm 30$  rpm when the stirring bar is centered in the beaker, as determined by a suitable optical tachometer.

#### Test Preparation—

Powders— Transfer the accurately weighed portion of the substance specified in the individual monograph to a 250-mL beaker, add 70 mL of water, and mix on the Magnetic Stirrer for 1 minute.

Effervescent Solids— Transfer an accurately weighed quantity, equivalent to the minimum labeled dosage, to a 250-mL beaker, add 10 mL of water, and swirl the beaker gently while allowing the reaction to subside. Add another 10 mL of water, and swirl gently. Wash the walls of the beaker with 50 mL of water, and mix on the Magnetic Stirrer for 1 minute.

Suspensions and Other Liquids— Shake the container until the contents are uniform, and determine the density. Transfer an accurately weighed quantity of the uniform mixture, equivalent to the minimum labeled dosage, to a 250-mL beaker, add water to make a total volume of about 70 mL, and mix on the Magnetic Stirrer for 1 minute.

Lozenges— Accurately weigh not fewer than 20 lozenges, and determine the average weight. Select and weigh 2 lozenges, and transfer them to a 250-mL beaker containing 70 mL of water.

Nonchewable Tablets— Weigh not fewer than 20 tablets, and determine the average tablet weight. Grind the tablets to a fine powder, mix to obtain a uniform mixture, and transfer an accurately weighed quantity of it, equivalent to the minimum labeled dosage, to a 250-mL beaker. If wetting is desired, add not more than 5 mL of alcohol (neutralized to an apparent pH of 3.5), and mix to wet the specimen thoroughly. Add 70 mL of water, and mix on the Magnetic Stirrer for 1 minute.

Chewable Tablets— Prepare as directed for Nonchewable Tablets.

Tablets That Are Required To Be Chewed— Transfer 1 Tablet to a 250-mL beaker, add 50 mL of water, and mix on the Magnetic Stirrer for 1 minute.

Capsules— Weigh accurately not fewer than 20 capsules. Remove the capsule contents completely, with the aid of a cotton swab if necessary. Accurately weigh the empty capsules, and determine the average weight of the contents per capsule. Mix the combined capsule contents to obtain a uniform mixture, and proceed as directed for Nonchewable Tablets, beginning with "transfer an accurately weighed quantity of it."

Procedure for Powders, Effervescent Solids, Suspensions and Other Liquids, Lozenges, Nonchewable Tablets, Chewable Tablets, and Capsules— Pipet 30.0 mL of 1.0 N hydrochloric acid VS into the Test Preparation while continuing to stir with the Magnetic Stirrer. [note—Where the acid-neutralizing capacity of the specimen under test is greater than 25 mEq, use 60.0 mL of 1.0 N hydrochloric acid VS, and make the appropriate modifications in the calculation.] Stir for 15 minutes, accurately timed, after the addition of the acid, begin to titrate immediately, and in a period not to exceed an additional 5 minutes, titrate the excess hydrochloric acid with 0.5 N sodium hydroxide VS to attain a stable (for 10 to 15 seconds) pH of 3.5. Calculate the number of mEq of acid consumed by the formula:

$$\text{Total mEq} = (30 \times \text{NHCl}) - (\text{VNaOH} \times \text{NNaOH})$$

in which NHCl and NNaOH are the normalities of the hydrochloric acid VS and the sodium hydroxide VS, respectively; and VNaOH is the volume of sodium hydroxide VS used for titration. Express the result in terms of mEq of acid consumed per g of the substance tested.

Procedure for Tablets That Are Required To Be Chewed— Pipet 30.0 mL of 1.0 N hydrochloric acid VS into the Test Preparation while continuing to stir with the Magnetic Stirrer for 10 minutes, accurately timed, after the addition of the acid. Discontinue stirring briefly, and without delay remove any gum base from the beaker using a long needle. Promptly rinse the needle with 20 mL of water, collecting the washing in the beaker, and resume stirring for 5 minutes, accurately timed, then begin to titrate immediately, and in a period not to exceed an additional 5 minutes, titrate the excess hydrochloric acid with 0.5 N sodium hydroxide VS to attain a stable (for 10 to 15 seconds) pH of 3.5. Calculate the number of mEq of acid consumed by the Tablet tested by the formula:

$$\text{Total mEq} = (30 \times \text{NHCl}) - (\text{VNaOH} \times \text{NNaOH})$$

in which the terms are as defined above.

Auxiliary Information— Please [check for your question in the FAQs](#) before contacting USP.

### 311 ALGINATES ASSAY

#### APPARATUS

The required apparatus (see Figure 1) contains a capillary metering valve, A, followed by a flowmeter, B, to control and monitor the flow of nitrogen through the system. Halogenated vinyl plastic tubing and a rubber fitting, C, are used to connect the flowmeter to a sidearm of a reaction flask, D. Flask D is a 250-ml round-bottom, boiling flask, resting in a suitable heating mantle, E. Flask D is provided with a 225-mm Hopkins coil reflux condenser, F. The condenser terminates in a U-shaped trap, G, which contains two 25-g bands of 20-mesh zinc, the bands being bounded and separated by three 3-inch plugs of glass wool. The trap terminates in an adapter, H, that by means of a halogenated vinyl plastic tubing and a twistcock connector, I, connects with a 250-ml gas washing bottle, J. The inlet (bubbling) tube extends almost to the bottom of the gas washing bottle, and it terminates in a fritted disk having a coarse porosity. The size of all glass joints is 24/40, except for the 45/50 joint of the gas washing bottle.

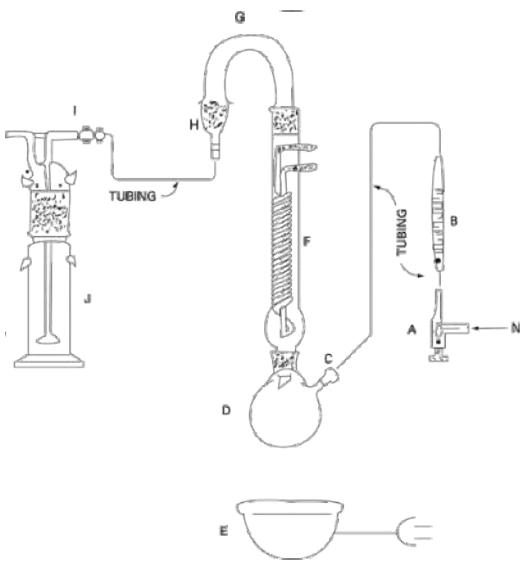

Fig. 1. Apparatus for Alginates Assay

#### SYSTEM SUITABILITY

Using d-glucuronolactone as the standard, proceed as directed for Procedure, but do not perform the preboiling steps. The system is suitable if the following criteria are met: (1) a blank determination results in a net titration value, C, between 0.02 and 0.06 mEq, calculated as follows:

$$\text{Ab} - \text{Bb}$$

in which Ab is the number of mEq of 0.25 N sodium hydroxide in the 25 mL used, and Bb is the number of mEq of 0.1 N hydrochloric acid used in the blank titration; and (2) the percentage of carbon dioxide, CO<sub>2</sub>, obtained from the standard is between 24.2% and 25.7%.

#### PROCEDURE

Unless otherwise directed in the individual monograph, transfer a specimen of about 250 mg, accurately weighed, into the reaction flask, D, add 50 mL of 0.1 N hydrochloric acid, insert several boiling chips, and connect the flask to the reflux condenser, F, using phosphoric acid as a lubricant. [note—Stopcock grease may be used for the other connections.] Connect

the nitrogen line to the sidearm of the flask, and adjust the flow of cooling water to about 2 L per minute.

[note—The following preboiling steps, outlined in this paragraph, are optional and need only be performed when the presence of inorganic carbonates is suspected.] Maintain the flow of nitrogen through the apparatus at 90 to 100 mL per minute. Raise the heating mantle, E, to the flask, heat the specimen to boiling, and boil gently for 2 minutes. Turn the heat off, lower the mantle, E, and allow to cool for about 10 minutes.

Connect the empty gas washing bottle assembly, J, and sweep the system with nitrogen at a rate of 90 to 100 mL per minute for 5 minutes. Reduce the nitrogen flow to 60 to 65 mL per minute, add 10 drops of butyl alcohol, 25.0 mL of 0.25 N sodium hydroxide VS, and 50 mL of distilled water into the bottle, rinsing down the inside of the gas washing bottle, and replace the cap. Detach the rubber fitting, C, from sidearm, and add 46 mL of hydrochloric acid through the sidearm of the boiling flask. Reattach the nitrogen line, raise the heating mantle, and heat the reaction mixture to boiling. After 2 hours of boiling, increase the nitrogen flow to 90 to 100 mL per minute, discontinue the heating, and lower the mantle. Allow to cool for 10 minutes. Disconnect, and disassemble the gas washing bottle. Using a directed stream of distilled water, thoroughly rinse all parts of the bubbling tube and cap, collecting the washings in the gas washing bottle. Use nitrogen to gently force all water out of the bubbling tube. To the bottle immediately add 10 mL of 10% barium chloride solution and a stirring bar. Insert a tight stopper, and stir gently for 1 minute. Allow to stand for at least 5 minutes. Add three drops of phenolphthalein TS, and titrate with 0.1 N hydrochloric acid VS.

Perform a blank determination (see Residual Titrations under [Titrimetry \(541\)](#)). Calculate the percentage of carbon dioxide, CO<sub>2</sub>, by the formula:

$$2200[(A - B) - C]/(1000W)(1 - D)$$

in which A is the number of mEq of 0.25 N sodium hydroxide in the 25 mL used; B is the number of mEq of 0.1 N hydrochloric acid used for the titration of the sample or the standard; C is the net titration value calculated in the blank determination; W is the weight, in g, of the sample or the standard taken; and D is the percentage expressed as a decimal (1 decimal place), obtained in the test for Loss on drying for the sample or for the standard.

\* This type of tubing is commonly referred to as Tygon tubing. This note is added for clarity and it does not constitute USP's endorsement of this product.

Auxiliary Information— Please [check for your question in the FAQs](#) before contacting USP.

### 331 AMPHETAMINE ASSAY

[USP Reference Standards \(11\)](#)—[USP Dextroamphetamine Sulfate RS](#).

Standard Preparation— Dissolve a suitable quantity of USP Dextroamphetamine Sulfate RS, accurately weighed, in 2 N sulfuric acid (saturated with chloroform), and dilute quantitatively with the same solvent to obtain a solution having a known concentration of about 0.5 mg of dextroamphetamine sulfate per mL.

Assay Preparation— Prepare as directed in the individual monograph.

Preparation of Chromatographic Column (see [Chromatography \(621\)](#))—Pack a pledge of fine glass wool in the base of a 25- × 300-mm chromatographic tube. Place 2 g of purified siliceous earth in a 100-mL beaker, add 1 mL of 0.1 N hydrochloric acid, and mix until a fluffy mixture is obtained. Transfer the mixture to the column, and tamp moderately to compress the material into a uniform mass. Transfer the Assay Preparation to the column, dry-rinse the beaker with 1 g of purified siliceous earth, and transfer to the column. Tamp a pledge of fine glass wool into place at the top of the column.

Procedure— Wash the column with 100 mL of chloroform previously saturated with water, and discard the washings. Place under the column, as a receiver, a 125-mL separator containing 10.0 mL of 2 N sulfuric acid previously saturated with chloroform. Pass through the column 35 mL of ammoniacal chloroform, prepared by equilibrating 2 mL of ammonium hydroxide and 100 mL of chloroform, and complete the elution with 70 mL of chloroform previously saturated with water. Remove the separator, shake vigorously for 1 minute, allow the layers to separate, discard the chloroform layer, and use the 10.0-mL acid solution of the sulfate salt of the amphetamine as the Assay Solution. Concomitantly determine the absorbance of the solution from the Standard Preparation and that of the Assay Solution in 1-cm cells at 280 nm and at the wavelength of maximum absorbance at about 257 nm, with a suitable spectrophotometer, using 2 N sulfuric acid previously saturated with chloroform as the blank. Record the absorbance of the solution from the Standard Preparation as AS and that of the Assay Solution as AU, and calculate as directed in the individual monograph.

Auxiliary Information— Please [check for your question in the FAQs](#) before contacting USP.

USP32-NF27 Page 141

### 341 ANTIMICROBIAL AGENTS—CONTENT

An essential component of Injections preserved in multiple-dose containers is the agent or agents present to reduce the hazard of having introduced, in the course of removing some of the contents, accidental microbial contamination of the contents remaining. It is a Pharmacopeial requirement that the presence and amount added of such agent(s) be declared on the label of the container. The methods provided herein for the most commonly used agents are to be used to demonstrate that the declared agent is present but does not exceed the labeled amount by more than 20% of the labeled amount.

The concentration of an antimicrobial preservative added to a multiple-dose or single-dose parenteral, otic, nasal, and ophthalmic preparation may diminish during the shelf life of the product. Because it is recognized that the antimicrobial preservative concentration in a given preparation may decrease during the product's shelf life, the manufacturer shall determine the lowest level at which the preservative is effective, and the product should be so formulated as to assure that this level is exceeded throughout the product's shelf life. At the time of its manufacture, the product should contain the declared amount of antimicrobial preservative (within  $\pm 20\%$  to allow for manufacturing and analytical variations). The quantitative label statement of the preservative content is not intended to mean that the labeled quantity is retained during the shelf life of the product; rather, it is a statement of the amount added, within process limits, and which is not exceeded by more than 20%. An example of such a label statement is "\_\_\_\_(unit) added as preservative." [note—"\_\_\_\_(unit)" would be a number followed by the unit of measurement, e.g., 0.015 mg per mL or 0.1%.]

The most commonly used agents include the two mercurials, phenylmercuric nitrate and thimerosal and the four homologous esters of p-hydroxybenzoic acid, phenol, benzyl alcohol,

and chlorobutanol. The methods for the first two named are polarographic, while quantitative gas chromatography is employed in the determination of the other agents.

#### GENERAL GAS CHROMATOGRAPHIC METHOD

The general procedures set forth in the following paragraphs are applicable to the quantitative determination of benzyl alcohol, chlorobutanol, phenol, and the methyl, ethyl, propyl, and butyl esters of *p*-hydroxybenzoic acid, the latter being treated as a group, the individual members of which, if present, are capable of separate determination. Prepare the Internal

Standard Solution and the Standard Preparation for each agent as directed individually below. Unless otherwise directed below, prepare the Test Preparation from accurately measured portions of the Internal Standard Solution and the sample under test, of such size that the concentration of the agent and the composition of the solvent correspond closely to the concentration and composition of the Standard Preparation. Suggested operating parameters of the gas chromatograph apparatus are given in the accompanying table, the carrier gas being helium or nitrogen, and the detector being the flame-ionization type.

##### Suggested Operating Parameters of Gas Chromatograph Apparatus

Agent	Column Size		Column Packing Phases and Support	Flow Rate, mL per minute	Column Temperature
	Length	ID			
Benzyl Alcohol	1.8 m	3 mm	5% G16/S1A	50	140 <sup>v</sup>
Chlorobutanol	1.8 m	2 mm	5% G16/S1A	20	110 <sup>a</sup>
Phenol	1.2 m	3 mm	5% G16/S1A	50	145 <sup>a</sup>
Parabens	1.8 m	2 mm	5% G2/S1A	20	150 <sup>a</sup>

##### Benzyl Alcohol

Internal Standard Solution— Dissolve about 380 mg of phenol in 10 mL of methanol contained in a 200-mL volumetric flask. Add water to volume, and mix.

Standard Preparation— Dissolve about 180 mg of [USP Benzyl Alcohol RS](#), accurately weighed, in 20.0 mL of methanol contained in a 100-mL volumetric flask. Add Internal Standard Solution to volume, and mix.

Procedure— Separately inject equal volumes (about 5  $\mu$ L) of the Standard Preparation and the Test Preparation into the chromatograph, record the chromatograms with the apparatus adjusted to the parameters set forth in the accompanying table, and measure the areas under the peaks for benzyl alcohol and phenol. Calculate the content, in mg per mL, of benzyl alcohol ( $C_7H_8O$ ) in the specimen taken by the formula:

$$100(C/V)(p1 / p2)(P2 / P1)$$

in which C is the concentration, in mg per mL, of benzyl alcohol in the Standard Preparation; V is the volume, in mL, of the specimen under test used in preparing each 100 mL of the Test Preparation; p1 and p2 are the peak areas for benzyl alcohol and phenol, respectively, obtained from the Test Preparation; and P1 and P2 are the peak areas of benzyl alcohol and phenol, respectively, obtained from the Standard Preparation.

##### Chlorobutanol

Internal Standard Solution— Transfer about 140 mg of benzaldehyde to a 100-mL volumetric flask, add 10 mL of methanol, and swirl to dissolve. Dilute with water to volume, and mix.

Standard Preparation— Transfer about 125 mg of [USP Chlorobutanol RS](#), accurately weighed, to a 25-mL volumetric flask. Add 2 mL of methanol, swirl to dissolve, dilute with water to volume, and mix. Transfer 5.0 mL of this solution and 5.0 mL of Internal Standard Solution to a 25-mL flask, and mix to obtain a solution having a known concentration of about 2.5 mg of chlorobutanol per mL.

Test Preparation— Quantitatively dilute, if necessary, an accurately measured volume of the specimen under test with methanol to obtain a solution containing not more than about 5.0 mg of chlorobutanol per mL. Combine 3.0 mL of this solution with 3.0 mL of Internal Standard Solution, and mix.

Chromatographic System (see [Chromatography](#) 621)— [note—See accompanying table for column dimensions, column packing phase and support, flow rate, and column temperature.] The injection port temperature is maintained at 180<sup>o</sup>, and the detector temperature is maintained at 220<sup>o</sup>. Chromatograph the Standard Preparation, and record the peak responses as directed for Procedure: the relative retention times are about 0.8 for benzaldehyde and 1.0 for chlorobutanol; the resolution, R, between benzaldehyde and the chlorobutanol is not less than 2.0; and the relative standard deviation for replicate injections is not more than 2.0%.

Procedure— Separately inject equal volumes (about 1  $\mu$ L) of the Standard Preparation and the Test Preparation into the chromatograph, record the chromatograms, and measure the areas for the major peaks. Calculate the quantity, in mg, of chlorobutanol ( $C_4H_7Cl_3O$ ) in each mL of the specimen under test by the formula:

$$C(L/D)(RU / RS)$$

in which C is the concentration, in mg per mL, of chlorobutanol, calculated on the anhydrous basis, in the Standard Preparation; L is the labeled quantity, in mg, of chlorobutanol in each mL of the specimen under test; D is the concentration, in mg per mL, of chlorobutanol in the Test Preparation, based on the volume of specimen under test taken and the extent of dilution; and RU and RS are the ratios of the chlorobutanol peak to the benzaldehyde peak obtained from the Test Preparation and the Standard Preparation, respectively.

##### Phenol

Internal Standard Solution— Pipet 1 mL of [USP Benzyl Alcohol RS](#) into a 500-mL volumetric flask, add methanol to volume, and mix.

Standard Preparation— Dissolve about 75 mg of [USP Phenol RS](#), accurately weighed, in 7.5 mL of methanol contained in a 100-mL volumetric flask. Add 20.0 mL of Internal Standard Solution, then add water to volume, and mix.

Procedure— Separately inject equal volumes (about 3  $\mu$ L) of the Standard Preparation and the Test Preparation into the chromatograph, record the chromatograms with the apparatus adjusted to the parameters set forth in the accompanying table, and measure the areas under the peaks for phenol and benzyl alcohol. Calculate the content, in mg per mL, of phenol ( $C_6H_6O$ ) in each mL of the specimen taken by the formula:

$$100(C/V)(p1 / p2)(P2 / P1)$$

in which C is the concentration, in mg per mL, of phenol in the Standard Preparation; V is the volume, in mL, of the specimen under test used in preparing each 100 mL of the Test Preparation; p1 and p2 are the peak areas for phenol and benzyl alcohol, respectively, obtained from the Test Preparation; and P1 and P2 are the peak areas of phenol and benzyl alcohol, respectively, obtained from the Standard Preparation.

##### Methylparaben and Propylparaben

Internal Standard Solution— Place about 200 mg of benzophenone in a 250-mL volumetric flask, dilute with ether to volume, and mix.

Standard Preparation— Place 100 mg of [USP Methylparaben RS](#) and 10 mg of [USP Propylparaben RS](#), each accurately weighed, in a 200-mL volumetric flask, dilute with Internal Standard Solution to volume, and mix. Place 10 mL of this solution in a 25-mL conical flask, and proceed as directed for Test Preparation, beginning with “Add 3 mL of pyridine.”

Test Preparation— Pipet 10 mL of the specimen under test and 10 mL of the Internal Standard Solution into a small separator. Shake vigorously, allow the layers to separate, draw off the aqueous layer into a second separator, and transfer the ether layer into a small flask through a funnel containing anhydrous sodium sulfate. Extract the aqueous layer with two 10-mL portions of ether, also filtering the extracts through the anhydrous sodium sulfate. Evaporate the combined extracts under a current of dry air until the volume is reduced to about 10 mL, then transfer the residue to a 25-mL conical flask. Add 3 mL of pyridine, complete the evaporation of the ether, and boil on a hot plate until the volume is reduced to about 1 mL.

Cool, and add 1 mL of a suitable silylation agent, such as bis(trimethylsilyl)trifluoracetamide, bis(trimethylsilyl)acetamide, or a mixture of hexamethyldisilazane and trimethylchlorosilane [2:1 or 3:1 (v/v)]. Mix, and allow to stand for not less than 15 minutes.

Procedure— Separately inject equal volumes (2  $\mu$ L) of the silylated solution from the Standard Preparation and the Test Preparation into the chromatograph, record the chromatograms with the apparatus adjusted to the parameters set forth in the accompanying table, and measure the areas under the peaks for methylparaben, propylparaben, and

benzophenone. Calculate the content, in  $\mu\text{g}$  per mL, of methylparaben (C<sub>8</sub>H<sub>8</sub>O<sub>3</sub>) in the sample under test by the formula:

$$10(\text{CM} / \text{V})(\text{p1} / \text{p3})(\text{P3} / \text{P1})$$

in which CM is the concentration, in  $\mu\text{g}$  per mL, of methylparaben in the Standard Preparation; V is the volume, in mL, of the specimen taken; p1 and p3 are the peak areas for methylparaben and benzophenone, respectively, obtained from the Test Preparation; and P1 and P3 are the peak areas of methylparaben and benzophenone, respectively, obtained from the Standard Preparation. Similarly, calculate the content, in  $\mu\text{g}$  per mL, of propylparaben (C<sub>10</sub>H<sub>12</sub>O<sub>3</sub>) in the specimen under test by the formula:

$$10(\text{CP} / \text{V})(\text{p2} / \text{p3})(\text{P3} / \text{P2})$$

in which CP is the concentration, in  $\mu\text{g}$  per mL, of propylparaben in the Standard Preparation; V is the volume, in mL, of the specimen taken; p2 and p3 are the peak areas for propylparaben and benzophenone, respectively, obtained from the Test Preparation; and P2 and P3 are the peak areas of propylparaben and benzophenone, respectively, obtained from the Standard Preparation.

Ethylparaben and butylparaben may be determined in a similar manner.

#### POLAROGRAPHIC METHOD

##### Phenylmercuric Nitrate

Standard Preparation— Dissolve about 100 mg of phenylmercuric nitrate, accurately weighed, in sodium hydroxide solution (1 in 250) contained in a 1000-mL volumetric flask, warming if necessary to effect solution, add the sodium hydroxide solution to volume, and mix. Pipet 10 mL of this solution into a 25-mL volumetric flask, and proceed as directed under Test Preparation, beginning with "add 2 mL of potassium nitrate solution (1 in 100)."

Test Preparation— Pipet 10 mL of the specimen under test into a 25-mL volumetric flask, add 2 mL of potassium nitrate solution (1 in 100) and 10 mL of pH 9.2 alkaline borate buffer (see under Buffer Solutions in the section [Reagents, Indicators, and Solutions](#)), and adjust to a pH of 9.2, if necessary, by the addition of 2 N nitric acid. Add 1.5 mL of freshly prepared gelatin solution (1 in 1000), then add the pH 9.2 alkaline borate buffer to volume, and mix.

Procedure— Pipet a portion of the Test Preparation into the polarographic cell, and deaerate by bubbling nitrogen through the solution for 15 minutes. Insert the dropping mercury electrode of a suitable polarograph (see [Polarography](#) 801), and record the polarogram from  $-0.6$  to  $-1.5$  volts versus the saturated calomel electrode. Determine the diffusion current of the Test Preparation, (id)U, as the difference between the residual current and the limiting current. Similarly and concomitantly determine the diffusion current, (id)S, of the Standard Preparation. Calculate the quantity, in  $\mu\text{g}$ , of phenylmercuric nitrate (C<sub>6</sub>H<sub>5</sub>HgNO<sub>3</sub>) in each mL of the specimen taken by the formula:

$$2.5\text{C}[(\text{id})\text{U} / (\text{id})\text{S}]$$

in which C is the concentration, in  $\mu\text{g}$  per mL, of phenylmercuric nitrate in the Standard Preparation.

##### Thimerosal

Standard Preparation— On the day of use, place about 25 mg of [USP Thimerosal RS](#), accurately weighed, in a 250-mL volumetric flask, add water to volume, and mix. Protect from light. Pipet 15 mL of this solution into a 25-mL volumetric flask, add 1.5 mL of gelatin solution (1 in 1000), then add potassium nitrate solution (1 in 100) to volume, and mix.

Test Preparation— Pipet 15 mL of the test specimen into a 25-mL volumetric flask, add 1.5 mL of gelatin solution (1 in 1000), add potassium nitrate solution (1 in 100) to volume, and mix.

Procedure— Transfer a portion of the Test Preparation to a polarographic cell, and deaerate by bubbling nitrogen through the solution for 15 minutes. Insert the dropping mercury electrode of a suitable polarograph (see [Polarography](#) 801), and record the polarogram from  $-0.2$  to  $-1.4$  volts versus the saturated calomel electrode. Determine the diffusion current, (id)U, as the difference between the residual current and the limiting current. Similarly and concomitantly determine the diffusion current, (id)S, of the Standard Preparation.

Calculate the quantity, in  $\mu\text{g}$ , of thimerosal (C<sub>6</sub>H<sub>9</sub>HgNaO<sub>2</sub>S) in each mL of the test specimen taken by the formula:

$$1.667\text{C}[(\text{id})\text{U} / (\text{id})\text{S}]$$

in which C is the concentration, in  $\mu\text{g}$  per mL, of thimerosal in the Standard Preparation; and the other terms are as defined therein.

Auxiliary Information— Please [check for your question in the FAQs](#) before contacting USP.

#### 345 ASSAY FOR CITRIC ACID/CITRATE AND PHOSPHATE

The following ion chromatographic general procedure is provided for the determination of citric acid/citrate and phosphate in compendial articles, when specified in the individual monographs. Identification tests for citrate and phosphate are provided separately under USP general chapter [Identification Tests—General](#) 191. The procedure for preparation of the Standard Preparations used for the assay depends on whether or not citrate and phosphate are being assayed concomitantly, as indicated below.

[USP Reference Standards](#) 11—[USP Citric Acid RS](#).

Mobile Phase— Transfer an appropriate volume of water (resistivity not less than 18 megohm-cm) to a suitable container, and degas with helium for not less than 20 minutes. Add an appropriate volume of 50% (w/w) carbonate-free sodium hydroxide or potassium hydroxide to obtain a 20 mM sodium hydroxide or potassium hydroxide solution. Alternatively, a 20 mM sodium hydroxide or potassium hydroxide eluant can be generated electrolytically using an automatic eluant generator. [note—Protect the Mobile Phase from atmospheric carbon dioxide.]

Standard Preparations— Use Standard Preparation 1 for an assay for citric acid/citrate only. Use Standard Preparation 2 when a concomitant assay for citrate and phosphate is intended.

Standard Preparation 1—Dissolve [USP Citric Acid RS](#) in freshly prepared 1 mM sodium hydroxide to obtain a solution having a known concentration of about 20  $\mu\text{g}$  per mL of citrate (C<sub>6</sub>H<sub>5</sub>O<sub>7</sub>).

Standard Preparation 2—Dissolve [USP Citric Acid RS](#) and monobasic sodium phosphate in freshly prepared 1 mM sodium hydroxide to obtain a solution having known concentrations of about 20  $\mu\text{g}$  per mL and 12  $\mu\text{g}$  per mL of citrate and phosphate (PO<sub>4</sub>), respectively.

Assay Preparation for Citric Acid/Citrate Assay— Unless stated otherwise in the monograph, dissolve an appropriate quantity of a solid dosage form in freshly prepared 1 mM sodium hydroxide to obtain a solution containing about 20  $\mu\text{g}$  per mL of citrate. If the dosage form is a liquid formulation, dilute with water, and add a freshly prepared sodium hydroxide solution to obtain a solution containing about 20  $\mu\text{g}$  per mL of citrate in 1 mM sodium hydroxide.

Assay Preparation for Phosphate Assay— Unless stated otherwise in the monograph, dissolve an appropriate quantity of a solid dosage form in freshly prepared 1 mM sodium

hydroxide to obtain a solution containing about 12  $\mu\text{g}$  per mL of phosphate. If the dosage form is a liquid formulation, dilute with water, and add a freshly prepared sodium hydroxide solution to obtain a solution containing about 12  $\mu\text{g}$  per mL of phosphate in 1 mM sodium hydroxide.

Chromatographic System (see [Chromatography 621](#))—The liquid chromatograph is equipped with a suitable anion trap column; a 4-mm  $\times$  50-mm guard column and a 4-mm  $\times$  250-mm analytical column, both packed with L61 packing; and an electrochemical detector with suppressed conductivity detection using either a micromembrane anion autosuppressor or a suitable chemical suppression system. All columns are maintained at a temperature of 30° and eluted at a flow rate of 2 mL per minute. [note—An anion trap column designed to remove trace anion contaminants in the Mobile Phase should be added to the column assembly before the injector.] Chromatograph Standard Preparation 1 or Standard Preparation 2, as appropriate, and record the peak area responses as directed for Procedure: the tailing factor is not more than 2.0; and the relative standard deviation of the peak areas for citrate (and phosphate where appropriate), for six replicate injections of Standard Preparation 1 or Standard Preparation 2, is not more than 1.5%.

Procedure— Separately inject 10  $\mu\text{L}$  each of the appropriate Standard Preparation and the Assay Preparation into the chromatograph, record the chromatograms, and measure the peak areas for citrate and phosphate, as appropriate. Determine the concentrations of citrate or phosphate in the portion of Assay Preparation taken by the formula:

$$\text{CS (rU / rS)}$$

in which CS is the concentration of citrate or phosphate, in  $\mu\text{g}$  per mL, in the appropriate Standard Preparation; and rU and rS are the peak areas of citrate or phosphate obtained from the Assay Preparation and the Standard Preparation, respectively.

Auxiliary Information— Please [check for your question in the FAQs](#) before contacting USP.

### 351 ASSAY FOR STEROIDS

The following procedure is applicable for determination of those Pharmacopeial steroids that possess reducing functional groups such as  $\text{C}=\text{O}$ -ketols.

Standard Preparation— Dissolve in alcohol a suitable quantity of the USP Reference Standard specified in the individual monograph, previously dried under the conditions specified in the individual monograph and accurately weighed, and dilute quantitatively and stepwise with alcohol to obtain a solution having a concentration of about 10  $\mu\text{g}$  per mL. Pipet 20 mL of this solution into a glass-stoppered, 50-mL conical flask.

Assay Preparation— Prepare as directed in the individual monograph.

Procedure— To each of the two flasks containing the Assay Preparation and the Standard Preparation, respectively, and to a similar flask containing 20.0 mL of alcohol to serve as the blank, add 2.0 mL of a solution prepared by dissolving 50 mg of blue tetrazolium in 10 mL of methanol, and mix. Then to each flask add 2.0 mL of a mixture of alcohol and tetramethylammonium hydroxide TS (9:1), mix, and allow to stand in the dark for 90 minutes. Without delay, concomitantly determine the absorbances of the solutions from the Assay Preparation and the Standard Preparation at about 525 nm, with a suitable spectrophotometer, against the blank. Calculate the result by the formula given in the individual monograph, in which C is the concentration, in  $\mu\text{g}$  per mL, of the Reference Standard in the Standard Preparation; and AU and AS are the absorbances of the solutions from the Assay Preparation and the Standard Preparation, respectively.

Auxiliary Information— Please [check for your question in the FAQs](#) before contacting USP.

USP32-NF27 Page 144

### 361 BARBITURATE ASSAY

Internal Standard, Internal Standard Solution, Standard Preparation, and Assay Preparation— Prepare as directed in the individual monograph.

Chromatographic System— Under typical conditions, the gas chromatograph is equipped with a flame-ionization detector and contains a 4-mm  $\times$  0.9-m glass column packed with 3% liquid phase G10 on support 80- to 100-mesh S1A. The column is maintained at a temperature of  $200 \pm 10^\circ$ , and the injection port and detector are maintained at about  $225^\circ$ , the column temperature being varied within the designated tolerance, as necessary, to meet System Suitability specifications and provide suitable retention times. Use a suitable carrier gas, such as dry nitrogen, at an appropriate flow rate, such as 60 to 80 mL per minute. Use on-column injection. [note—If the instrument is not equipped for on-column injection, use an injection port lined with glass that has been washed successively with chromic acid cleansing solution, water, methanol, chloroform, a 1 in 10 solution of trimethylchlorosilane in chloroform, and chloroform.]

System Suitability (see [Chromatography 621](#))— Chromatograph five replicate injections of the Standard Preparation, and record peak responses as directed for Procedure: the relative standard deviation for the ratio RS is not more than 1.5%. In a suitable chromatogram, the resolution, R, between the barbituric acid and the Internal Standard is not less than the value given in the individual monograph, and the tailing factor, T, for each of the two peaks is not more than 2.0.

Procedure— Inject a suitable portion (about 5  $\mu\text{L}$ ) of the Standard Preparation into a suitable gas chromatograph, and record the chromatogram. Similarly inject a suitable portion of the Assay Preparation, and record the chromatogram. Calculate the content of the barbituric acid or barbituric acid in the assay specimen by the formula given in the individual monograph, in which RU is the ratio of the peak response of the barbituric acid to that of the Internal Standard obtained for the Assay Preparation; QS is the ratio of the weight of the barbituric acid to that of the Internal Standard in the Standard Preparation; Ci is the concentration, in mg per mL, of Internal Standard in the Internal Standard Solution; and RS is the ratio of the peak response of the barbituric acid to that of the Internal Standard in the Standard Preparation.

Auxiliary Information— Please [check for your question in the FAQs](#) before contacting USP.

## 371 COBALAMIN RADIOTRACER ASSAY

All radioactive determinations required by this method should be made with a suitable counting assembly over a period of time optimal for the particular counting assembly used. All procedures should be performed in replicate to obtain the greatest accuracy.

USP Reference Standards (11) — [USP Cyanocobalamin RS](#).

**Cyanocobalamin Tracer Reagent**— Dilute an accurately measured volume of a solution of radioactive cyanocobalamin\* with water to yield a solution having a radioactivity between 500 and 5000 counts per minute per mL. Add 1 drop of cresol per L of solution prepared, and store in a refrigerator.

**Standardization**— Prepare a solution of a weighed quantity of [USP Cyanocobalamin RS](#) in water to contain 20 to 50 µg per mL. Perform the entire assay on a 10.0-mL portion of this solution, proceeding as directed under Assay Preparation, beginning with "Add water to make a measured volume."

**Cresol—Carbon Tetrachloride Solution**— Mix equal volumes of carbon tetrachloride and freshly distilled cresol.

**Phosphate—Cyanide Solution**— Dissolve 100 mg of potassium cyanide in 1000 mL of a saturated solution of dibasic sodium phosphate, and mix.

**Butanol-Benzalkonium Chloride Solution**— Dilute benzalkonium chloride solution (17 in 100) with water (3:1), and mix with 36 volumes of butyl alcohol.

**Alumina-Resin Column**— Place a pledge of glass wool in the bottom of a constricted glass tube such as a 50-mL buret. With the tube held in an upright position, add a volume of a slurry of ion-exchange resin (see in the section [Reagents, Indicators, and Solutions](#)), in water, sufficient to give a column of settled resin 7 cm in height. When the solid has settled somewhat, allow the water to drain so that there is only 1 cm of liquid above the resin column, and tamp the resin lightly. Then add a volume of a slurry of anhydrous alumina (not acid-washed) in water sufficient to increase the height of the settled column to 10 cm, and allow the water to drain to about 1 cm from the top of the alumina. Add a pledge of glass wool, and wash the column, using a total of 50 mL of water, and again drain to within 1 cm of the top of the column. Prepare a fresh column for each determination.

**Assay Preparation**— Transfer to a beaker a weighed quantity or measured volume of the preparation to be assayed, equivalent in vitamin B12 activity to that of 200 to 500 µg of cyanocobalamin. Add water to make a measured volume of not less than 25 mL, then add 5.0 mL of Cyanocobalamin Tracer Reagent. Add, while working under a hood, 5 mg of sodium nitrite and 2 mg of potassium cyanide for each mL of the resulting solution. Adjust the solution with diluted hydrochloric acid to a pH of approximately 4, and heat on a steam bath for 15 minutes. Cool, and adjust the solution with 1 N sodium hydroxide to a pH between 7.6 and 8.0. Centrifuge or filter to remove any undissolved solids.

**Procedure**— Transfer the Assay Preparation to a 250-mL centrifuge bottle, add 10 mL of Cresol—Carbon Tetrachloride Solution, suitably close the bottle with a glass, polyethylene, or foil-wrapped rubber stopper, shake vigorously for 2 to 5 minutes, and centrifuge. Remove and save the lower, solvent layer. Repeat the extraction using a 5-mL portion of Cresol—Carbon Tetrachloride Solution, and combine the lower, solvent-layer extracts in a centrifuge bottle or separator of 50- to 100-mL capacity.

Wash the combined extracts with successive 10-mL portions of 5 N sulfuric acid until the last washing is practically colorless (two washings usually suffice). During each washing, shake for 2 to 5 minutes, allow the layers to separate, centrifuge, if necessary, and discard the acid layer. Wash further with two successive 10-mL portions of Phosphate—Cyanide Solution. Finally, wash with 10 mL of water. Discard all of the washings.

To the washed extract add 30 mL of a mixture of Butanol-Benzalkonium Chloride Solution and carbon tetrachloride (2:1). Extract with two 5-mL portions of water, each time shaking vigorously for 1 minute, centrifuging, and removing and saving the upper, aqueous layer.

Pass the combined aqueous extracts through the Alumina-Resin Column at a rate of about 1 mL per minute, maintaining a 1-cm layer of liquid on the head of the column by adding water as needed. Discard as much of the forerun as is colorless (usually about 5 mL), and collect the colored eluate (usually about 10 mL) in a 50-mL centrifuge tube or separator containing 500 µL of diluted acetic acid. Extract the eluate by shaking for 2 to 5 minutes with 5 mL of Cresol—Carbon Tetrachloride Solution, and discard the upper, aqueous layer. To the extract add 5.0 mL of water, 5 mL of carbon tetrachloride, and 10 mL of butyl alcohol. Shake, allow to separate until the upper layer is clear, and remove the upper, aqueous layer.

Determine the absorbances of the aqueous extract, in a 1-cm cell, at 361 nm and 550 nm, with a suitable spectrophotometer, using a tungsten light source. Make the 361-nm reading using a filter capable of reducing stray light. Calculate the ratio A361/A550: the purity of the aqueous extract is acceptable if the ratio is between 3.10 and 3.40. If a ratio outside this range is observed, purify the aqueous extract by repeating the extraction cycle, proceeding as directed in the foregoing paragraph.

If an acceptable absorbance ratio is observed in the aqueous extract, determine the radioactivity, in counts per minute, using a suitable counter over a period optimal for the particular counting assembly used. Average the results, and correct the average for the observed background radioactivity determined over two or more 30-minute periods.

**Calculation**— Calculate the cobalamin content, expressed in µg of cyanocobalamin, of the portion taken for assay by the formula:

$$R(CS / CU)(AU / AS)$$

in which R is the quantity, in µg, of cyanocobalamin in the portion of the standard solution taken; CS and CU are the corrected average radioactivity values, expressed in counts per minute per mL, of the standard and assay solutions, respectively; and AU and AS are the absorbances determined at 361 nm of the assay and standard solutions, respectively.

\* A solution of cyanocobalamin made radioactive by the incorporation of 60Co is available from Merck and Co., Inc., Rahway, NJ 07065.

**Auxiliary Information**— Please [check for your question in the FAQs](#) before contacting USP.

USP32-NF27 Page 145

## 381 ELASTOMERIC CLOSURES FOR INJECTIONS

Change to read:

## INTRODUCTION

Elastomeric closures for containers used in the types of preparations defined in the general test chapter [Injections](#) (1) are made of materials obtained by vulcanization (cross-linking) polymerization, polyaddition, or polycondensation of macromolecular organic substances (elastomers). Closure formulations contain natural or synthetic elastomers and inorganic and organic additives to aid or control vulcanization, impart physical and chemical properties or color, or stabilize the closure formulation.

- This chapter applies to closures used for long-term storage of preparations defined in the general test chapter [Injections](#) (1). Such closures are typically used as part of a vial, bottle, or pre-fill syringe package system. • (RB 1-May-2009)

This chapter applies to closures formulated with natural or synthetic elastomeric substances. This chapter does not apply to closures made from silicone elastomer; however, it does apply to closures treated with silicone (e.g., Dimethicone, NF). When performing the tests in this chapter, it is not required that closures be treated with silicone, although there is no restriction prohibiting the use of siliconized closures.

- This chapter also applies to closures coated with other lubricious materials (e.g., materials chemically or mechanically bonded to the closure) that are not intended to, and in fact do not provide, a barrier to the base elastomer. When performing the tests, closures with lubricious non-barrier coatings are to be tested in their coated state.

The following comments relate solely to closures laminated or coated with materials intended to provide, or in fact function as, a barrier to the base elastomer (e.g., PTFE or lacquer coatings). It is not permissible to use a barrier material in an attempt to change a closure that does not meet compendial requirements to one that does conform. Therefore, all Physicochemical Tests apply to the base formula of such closures, as well as to the coated or laminated closure. To obtain Physicochemical Tests results, the tests are to be performed on uncoated or non-laminated closures of the same elastomeric compound, as well as to the laminated or coated closure. The Functionality Tests apply to and are to be performed using the laminated or coated elastomeric closure. Biological Tests apply to the lamination or coating material, as well as to the base formula. Biological Tests may be performed on the laminated or coated closure, or they may be performed on the laminate/coating material and the uncoated or non-laminated closures of the same elastomeric compound. In the latter case, the results are to be reported separately. The base formula used for physicochemical or biological tests intended to support the compendial compliance of a barrier-coated closure should be similar to the corresponding coated closure in configuration and size.

For all [Elastomeric Closures for Injection](#) (381) tests performed on any closure type, it is important to document the closure being tested, including a full description of the elastomer, and any lubrication, coating, laminations, or treatments applied. • (RB 1-May-2009)

This chapter states test limits for Type I and Type II elastomeric closures. Type I closures are those used for aqueous preparations. Type II closures are typically intended for nonaqueous preparations and are those which, having properties optimized for special uses, may not meet all requirements listed for Type I closures because of physical configuration, material of construction, or both. If a closure fails to meet one or more of the Type I test requirements, but still meets the Type II requirements for the test(s), the closure is assigned a final classification of Type II.

This chapter is intended as an initial screen to identify elastomeric closures that might be appropriate for use with injectable preparations on the basis of their biological compatibility, their aqueous extract physicochemical properties, and their functionality. All elastomeric closures suitable for use with injectable preparations comply with either Type I or Type II test limits. However, this specification is not intended to serve as the sole evaluation criteria for the selection of such closures.

The following closure evaluation requirements are beyond the scope of this chapter:

- The establishment of closure identification tests and specifications
- The verification of closure-product physicochemical compatibility
- The identification and safety determination of closure leachables found in the packaged product
- The verification of packaged product closure functionality under actual storage and use conditions

The manufacturer of the injectable product (the end user) must obtain from the closure supplier an assurance that the composition of the closure does not vary and that it is the same as that of the closure used during compatibility testing. When the supplier informs the end user of changes in the composition, compatibility testing must be repeated, totally or partly, depending on the nature of the changes. Closures must be properly stored, cleaned for removal of environmental contaminants and endotoxins, and sterilized prior to use in packaging injectable products.

## CHARACTERISTICS

Elastomeric closures are translucent or opaque and have no characteristic color, the latter depending on the additives used. They are homogeneous and practically free from flash and adventitious materials (e.g., fibers, foreign particles, and waste rubber.)

## IDENTIFICATION

Closures are made of a wide variety of elastomeric materials and optional polymeric coatings. For this reason, it is beyond the scope of this chapter to specify identification tests that encompass all possible closure presentations. However, it is the responsibility of the closure supplier and the injectable product manufacturer (the end user) to verify the closure elastomeric formulation and any coating or laminate materials used according to suitable identification tests. Examples of some of the analytical test methodologies that may be used include specific gravity, percentage of ash analysis, sulfur content determination, FTIR-ATR test, thin-layer chromatography of an extract, UV absorption spectrophotometry of an extract, or IR absorption spectrophotometry of a pyrolyzate.

Change to read:

## TEST PROCEDURES

Elastomeric closures shall conform to biological, physicochemical, and functionality requirements both as they are shipped by the closure supplier to the injectable product manufacturer (the end user), and in their final ready-to-use state by the end user.

For those elastomeric closures processed by the supplier prior to distribution to the end user, the supplier shall demonstrate compendial conformance of closures exposed to such processing and/or sterilization steps. Similarly, if elastomeric closures received by the end user are subsequently processed or sterilized, the end user is responsible for demonstrating the continued conformance of closures to compendial requirements subsequent to such processing and/or sterilization conditions (i.e., in their ready-to-use state). This is especially important if closures shall be exposed to processes or conditions that may significantly impact the biological, physicochemical, or functionality characteristics of the closure (e.g., gamma irradiation).

For closures that are normally lubricated •with silicone• (RB 1-May-2009) prior to use, it is permissible to perform physicochemical testing on non-lubricated closures, in order to avoid potential method interference and/or difficulties in interpreting test results. •For closures supplied with other lubricious non-barrier coatings, all tests are to be performed using the coated closure.

For closures coated or laminated with coatings intended to provide a barrier function (e.g., PTFE or lacquer coatings), physicochemical compendial tests apply to the uncoated base elastomer, as well as to the coated closure. In this case, suppliers are responsible for demonstrating physicochemical compendial compliance of the coated closure, as well as of the uncoated closure, processed or treated in a manner simulating conditions typically followed by the supplier for such coated closures prior to shipment to the end user. The uncoated closure subject to physicochemical tests should be similar to the corresponding coated closure in size and configuration. End users of coated closures are also responsible for demonstrating the continued physicochemical compendial conformance of the coated closure, processed or treated in a manner simulating conditions typically employed by the end user prior to use. • (RB 1-May-2009)

In all cases, it is appropriate to document all conditions of closure processing, pretreatment, sterilization or lubrication when reporting test results.

• [Table 1](#) summarizes the testing requirements of closures, and the responsibilities of the supplier and the end user.

Table 1

Closure Types (As Supplied or Used)	Test Requirements

#### BIOLOGICAL TESTS

Two stages of testing are indicated. The first stage is the performance of an in vitro test procedure as described in general test chapter [Biological Reactivity Tests, In Vitro](#) (87). Materials that do not meet the requirements of the in vitro test are subjected to the second stage of testing, which is the performance of the in vivo tests, Systemic Injection Test and Intracutaneous Test, according to the procedures set forth in the general test chapter [Biological Reactivity Tests, In Vivo](#) (88). Materials that meet the requirements of the in vitro test are not required to undergo in vivo testing.

Type I and Type II closures must both conform to the requirements of either the in vitro or the in vivo biological reactivity tests. [note—Also see the general information chapter [The Biocompatibility of Material Used in Drug Containers, Medical Devices, and Implants](#) (1031).]

#### PHYSICOCHEMICAL TESTS

##### Preparation of Solution S

Place whole, uncut closures corresponding to a surface area of  $100 \pm 10 \text{ cm}^2$  into a suitable glass container. Cover the closures with 200 mL of Purified Water or Water for Injection. If it is not possible to achieve the prescribed closure surface area ( $100 \pm 10 \text{ cm}^2$ ) using uncut closures, select the number of closures that will most closely approximate  $100 \text{ cm}^2$ , and adjust the volume of water used to the equivalent of 2 mL per each 1  $\text{cm}^2$  of actual closure surface area used. Boil for 5 minutes, and rinse five times with cold Purified Water or Water for Injection

Place the washed closures into a Type I glass wide-necked flask (see [Containers—Glass](#) (660)), add the same quantity of Purified Water or Water for Injection initially added to the closures, and weigh. Cover the mouth of the flask with a Type I glass beaker. Heat in an autoclave so that a temperature of  $121 \pm 2^\circ\text{C}$  is reached within 20 to 30 minutes, and maintain this temperature for 30 minutes. Cool to room temperature over a period of about 30 minutes. Add Purified Water or Water for Injection to bring it up to the original mass. Shake, and immediately decant and collect the solution. [note—This solution must be shaken before being used in each of the tests.]

##### Preparation of Blank

Prepare a blank solution similarly, using 200 mL of Purified Water or Water for Injection omitting the closures.

##### Appearance of Solution (Turbidity/Opalescence and Color)

##### Determination of Turbidity (Opalescence)

note—The determination of turbidity may be performed by visual comparison (Procedure A), or instrumentally using a suitable ratio turbidimeter (Procedure B). For a discussion of turbidimetry, see [Spectrophotometry and Light-Scattering](#) (851). Instrumental assessment of clarity provides a more discriminatory test that does not depend on the visual acuity of the analyst.

Hydrazine Sulfate Solution—Dissolve 1.0 g of hydrazine sulfate, in water and dilute with water to 100.0 mL. Allow to stand for 4 to 6 hours.

Hexamethylenetetramine Solution—Dissolve 2.5 g of hexamethylenetetramine in 25.0 mL of water in a 100 mL glass—stoppered flask.

Opalescence Stock Suspension—Add 25.0 mL of Hydrazine Sulfate Solution to the Hexamethylenetetramine Solution in the flask. Mix, and allow to stand for 24 hours. This suspension is stable for 2 months, provided it is stored in a glass container free from surface defects. The suspension must not adhere to the glass and must be well mixed before use.

Opalescence Standard Suspension—Prepare a suspension by diluting 15.0 mL of the Opalescence Stock Suspension with water to 1000.0 mL. Opalescence Standard Suspension is stable for about 24 hours after preparation.

Reference Suspensions—Prepare according to [Table 2](#). Mix and shake before use. [note—Stabilized formazin suspensions that can be used to prepare stable, diluted turbidity standards are available commercially and may be used after comparison with the standards prepared as described.]

Table 2

	Reference Suspension A	Reference Suspension B	Reference Suspension C	Reference Suspension D
Standard of Opalescence	5.0 mL	10.0 mL	30.0 mL	50.0 mL
Water	95.0 mL	90.0 mL	70.0 mL	50.0 mL
Nephelometric turbidity units	3 NTU	6 NTU	18 NTU	30 NTU

Procedure A: Visual Comparison—Use identical test tubes made of colorless, transparent, neutral glass with a flat base and an internal diameter of 15 to 25 mm. Fill one tube to a depth of 40 mm with Solution S, one tube to the same depth with water, and four others to the same depth with Reference Suspensions A, B, C, and D. Compare the solutions in diffuse daylight 5 minutes after preparation of the Reference Suspensions, viewing vertically against a black background. The light conditions shall be such that Reference Suspension

A can be readily distinguished from water and that Reference Suspension B can be readily distinguished from Reference Suspension A.

REQUIREMENT— Solution S is not more opalescent than Reference Suspension B for Type I closures, and not more opalescent than Reference Suspension C for Type II closures.

Solution S is considered clear if its clarity is the same as that of water when examined as described above, or if its opalescence is not more pronounced than that of Reference Suspension A (refer to [Table 3](#)).

Procedure B: Instrumental Comparison— Measure the turbidity of the Reference Suspensions in a suitable calibrated turbidimeter (see [Spectrophotometry and Light Scattering](#) (851)). The blank should be run and the results corrected for the blank. Reference Suspensions A, B, C, and D represent 3, 6, 18 and 30 Nephelometric Turbidity Units (NTU), respectively. Measure the turbidity of Solution S using the calibrated turbidimeter.

REQUIREMENT— The turbidity of Solution S is not greater than that for Reference Suspension B (6 NTU FTU) for Type I closures, and is not greater than that for Reference Suspension C (18 NTU FTU) for Type II closures (refer to [Table 3](#)).

Table 3

	Comparison Method	
Opalescence Requirements	Procedure A (Visual)	Procedure B (Instrumental)
Type I closures	no more opalescent than Suspension B	no more than 6 NTU
Type II closures	no more opalescent than Suspension C	no more than 18 NTU

#### Determination of Color

Color Standard— Prepare a solution by diluting 3.0 mL of Matching Fluid O (see [Color and Achromicity](#) (631)) with 97.0 mL of diluted hydrochloric acid.

Procedure— Use identical tubes made of colorless, transparent, neutral glass with a flat base and an internal diameter of 15 to 25 mm. Fill one tube to a depth of 40 mm with Solution S, and the second with Color Standard. Compare the liquids in diffuse daylight, viewing vertically against a white background.

Requirement— Solution S is not more intensely colored than the Color Standard.

#### Acidity or Alkalinity

Bromothymol Blue Solution— Dissolve 50 mg of bromothymol blue in a mixture of 4 mL of 0.02 M sodium hydroxide and 20 mL of alcohol. Dilute with water to 100 mL.

Procedure— To 20 mL of Solution S add 0.1 mL of Bromothymol Blue Solution. If the solution is yellow, titrate with 0.01 N sodium hydroxide until a blue endpoint is reached. If the solution is blue, titrate with 0.01 N hydrochloric acid until a yellow endpoint is reached. If the solution is green, it is neutral and no titration is required.

Blank Correction— Test 20 mL of Blank similarly. Correct the results obtained for Solution S by subtracting or adding the volume of titrant required for the Blank, as appropriate. ([Reference Titrimetry](#) (541)).

Requirement— Not more than 0.3 mL of 0.01 N sodium hydroxide produces a blue color, or not more than 0.8 mL of 0.01 N hydrochloric acid produces a yellow color, or no titration is required.

#### Absorbance

Procedure— [note—Perform this test within 5 hours of preparing Solution S.] Filter Solution S through a 0.45-μm pore size filter, discarding the first few mL of filtrate. Measure the absorbance of the filtrate at wavelengths between 220 and 360 nm in a 1-cm cell using the blank in a matched cell in the reference beam. If dilution of the filtrate is required before measurement of the absorbance, correct the test results for the dilution.

Requirement— The absorbances at these wavelengths do not exceed 0.2 for Type I closures or 4.0 for Type II closures.

#### Reducing Substances

Procedure— [note—Perform this test within 4 hours of preparing Solution S.] To 20.0 mL of Solution S add 1 mL of diluted sulfuric acid and 20.0 mL of 0.002 M potassium permanganate. Boil for 3 minutes. Cool, add 1 g of potassium iodide, and titrate immediately with 0.01 M sodium thiosulfate, using 0.25 mL of starch solution TS as the indicator. Perform a titration using 20.0 mL of blank and note the difference in volume of 0.01 M sodium thiosulfate required.

Requirement— The difference between the titration volumes is not greater than 3.0 mL for Type I closures and not greater than 7.0 mL for Type II closures.

#### Heavy Metals

Procedure— Proceed as directed for Method 1 under [Heavy Metals](#) (231). Prepare the Test Preparation using 10.0 mL of Solution S.

Requirement— Solution S contains not more than 2 ppm of heavy metals as lead.

#### Extractable Zinc

Test Solution— Prepare a Test Solution by diluting 10.0 mL of Solution S to 100 mL with 0.1 N hydrochloric acid. Prepare a test blank similarly, using the Blank for Solution S.

Zinc Standard Solution— Prepare a solution (10 ppm Zn) by dissolving zinc sulfate in 0.1 N hydrochloric acid.

Reference Solutions— Prepare not fewer than 3 Reference Solutions by diluting the Zinc Standard Solution with 0.1 N hydrochloric acid. The concentrations of zinc in these Reference Solutions are to span the expected limit of the Test Solution.

Procedure— Use a suitable atomic absorption spectrophotometer (see [Spectrophotometry and Light Scattering](#) (851)) equipped with a zinc hollow-cathode lamp and an air-acetylene flame. An alternative procedure such as an appropriately validated inductively coupled plasma analysis (ICP) may be used.

Test each of the Reference Solutions at the zinc emission line of 213.9 nm at least 3 times. Record the steady readings. Rinse the apparatus with the test blank solution each time, to ensure that the reading returns to initial blank value. Prepare a calibration curve from the mean of the readings obtained for each Reference Solution. Record the absorbance of the Test Solution. Determine the ppm zinc concentration of the Test Solution using the calibration curve.

Requirement— Solution S contains not more than 5 ppm of extractable zinc.

#### Ammonium

Alkaline Potassium Tetraiodomercurate Solution— Prepare a 100 mL solution containing 11 g of potassium iodide and 15 g of mercuric iodide in water. Immediately before use, mix 1 volume of this solution with an equal volume of a 250 g per L solution of sodium hydroxide.

Test Solution— Dilute 5 mL of Solution S to 14 mL with water. Make alkaline if necessary by adding 1 N sodium hydroxide, and dilute with water to 15 mL. Add 0.3 mL of Alkaline Potassium Tetraiodomercurate Solution, and close the container.

Ammonium Standard Solution— Prepare a solution of ammonium chloride in water (1 ppm NH<sub>4</sub>). Mix 10 mL of the 1 ppm ammonium chloride solution with 5 mL water and 0.3 mL of Alkaline Potassium Tetraiodomercurate Solution. Close the container.

Requirement— After 5 minutes, any yellow color in the Test Solution is no darker than the Ammonium Standard Solution (no more than 2 ppm of NH<sub>4</sub> in Solution S).

#### Volatile Sulfides

Procedure— Place closures, cut if necessary, with a total surface area of  $20 \pm 2 \text{ cm}^2$  in a 100-mL flask, and add 50 mL of a 20 g per L citric acid solution. In the same manner and at the same time, prepare a control solution in a separate 100-mL flask by dissolving 0.154 mg of sodium sulfide in 50 mL of a 20 g per L citric acid solution. Place a piece of lead acetate paper over the mouth of each flask, and hold the paper in position by placing over it an inverted weighing bottle. Heat the flasks in an autoclave at  $121 \pm 2^\circ$  for 30 minutes.

Requirement— Any black stain on the paper produced by Solution S is not more intense than that produced by the control solution.

#### FUNCTIONALITY TESTS

NOTE—Samples treated as described for preparation of Solution S and air dried should be used for Functionality Tests of Penetrability, Fragmentation, and Self-Sealing Capacity. Functionality Tests are performed on closures intended to be pierced by a hypodermic needle. The Self-Sealing Capacity test is required only for closures intended for multiple-dose containers. The needle specified for each test is a lubricated long bevel (bevel angle  $12 \pm 2^\circ$ ) hypodermic needle<sup>1</sup>.

##### Penetrability

Procedure— Fill 10 suitable vials to the nominal volume with water, fit the closures to be examined, and secure with a cap. Using a new hypodermic needle as described above for each closure, pierce the closure with the needle perpendicular to the surface.

Requirement— The force for piercing is no greater than 10 N (1 kgf) for each closure, determined with an accuracy of  $\pm 0.25$  N (25 gf).

##### Fragmentation

Closures for Liquid Preparations— Fill 12 clean vials with water to 4 mL less than the nominal capacity. Fit the closures to be examined, secure with a cap, and allow to stand for 16 hours.

Closures for Dry Preparations— Fit closures to be examined into 12 clean vials, and secure each with a cap.

Procedure— Using a hypodermic needle as described above fitted to a clean syringe, inject into each vial 1 mL of water while removing 1 mL of air. Repeat this procedure 4 times for each closure, piercing each time at a different site. Use a new needle for each closure, checking that it is not blunted during the test. Filter the total volume of liquid in all the vials through a single filter with a nominal pore size no greater than 0.5  $\mu\text{m}$ . Count the rubber fragments on the surface of the filter visible to the naked eye.

Requirement— There are no more than 5 fragments visible. This limit is based on the assumption that fragments with a diameter  $>50 \mu\text{m}$  are visible to the naked eye. In case of doubt or dispute, the particles are examined microscopically to verify their nature and size.

##### Self-Sealing Capacity

Procedure— Fill 10 suitable vials with water to the nominal volume. Fit the closures that are to be examined, and cap. Using a new hypodermic needle as described above for each closure, pierce each closure 10 times, piercing each time at a different site. Immerse the 10 vials in a solution of 0.1% (1 g per L) methylene blue, and reduce the external pressure by 27 kPa for 10 minutes. Restore to atmospheric pressure, and leave the vials immersed for 30 minutes. Rinse the outside of the vials.

Requirement— None of the vials contain any trace of blue solution.

1 Refer to ISO 7864, Sterile hypodermic needles for single use with an external diameter of 0.8 mm (21 Gauge).

Auxiliary Information— Please [check for your question in the FAQs](#) before contacting USP.

USP32-NF27 Page 145

Pharmacopeial Forum: Volume No. 30(1) Page 220

391 EPINEPHRINE ASSAY

[USP Reference Standards](#) 11 — [USP Epinephrine Bitartrate RS](#).

Ferro-citrate Solution— On the day needed, dissolve 1.5 g of ferrous sulfate in 200 mL of water to which have been added 1.0 mL of dilute hydrochloric acid (1 in 12) and 1.0 g of sodium bisulfite. Dissolve 500 mg of sodium citrate in 10 mL of this solution, and mix.

Buffer Solution— In a 50-mL volumetric flask mix 4.2 g of sodium bicarbonate, 5.0 g of potassium bicarbonate, and 18 mL of water (not all of the solids will dissolve at this stage). To another 18 mL of water add 3.75 g of aminoacetic acid and 1.7 mL of 6 N ammonium hydroxide, mix to dissolve, and transfer this solution to the 50-mL volumetric flask containing the other mixture. Dilute with water to volume, and mix until solution is complete.

Standard Preparation— Transfer about 18 mg of [USP Epinephrine Bitartrate RS](#), accurately weighed, to a 100-mL volumetric flask with the aid of 20 mL of sodium bisulfite solution (1 in 50), dilute with water to volume, and mix. Transfer 5.0 mL of this solution to a 50-mL volumetric flask, dilute with sodium bisulfite solution (1 in 500) to volume, and mix. [note—Make the final dilution when the assay is carried out.] The concentration of [USP Epinephrine Bitartrate RS](#) in the Standard Preparation is about 18  $\mu\text{g}$  per mL.

Assay Preparation— Transfer to a 50-mL volumetric flask an accurately measured volume of the injection under assay, equivalent to about 500  $\mu\text{g}$  of epinephrine, dilute with sodium bisulfite solution (1 in 500) to volume, if necessary, and mix. [note—The final concentration of sodium bisulfite is in the range of 1 to 3 mg per mL, any bisulfite present in the injection under assay being taken into consideration.]

Procedure— Into three 50-mL glass-stoppered conical flasks transfer, separately, 20.0-mL aliquots of the Standard Preparation, the Assay Preparation, and sodium bisulfite solution (1 in 500) to provide the blank. To each flask add 200  $\mu\text{L}$  of Ferro-citrate Solution and 2.0 mL of Buffer Solution, mix, and allow the solutions to stand for 30 minutes. Determine the absorbances of the solutions in 5-cm cells at the wavelength of maximum absorbance at about 530 nm, with a suitable spectrophotometer, using the blank to set the instrument.

Calculate the quantity, in mg, of epinephrine ( $\text{C}_9\text{H}_{13}\text{NO}_3$ ) in each mL of the injection taken by the formula:

$$(183.21 / 333.30)(0.05C / V)(AU / AS)$$

in which 183.21 and 333.30 are the molecular weights of epinephrine and epinephrine bitartrate, respectively; C is the concentration, in  $\mu\text{g}$  per mL, of [USP Epinephrine Bitartrate RS](#) in the Standard Preparation; and V is the volume, in mL, of injection taken.

Auxiliary Information— Please [check for your question in the FAQs](#) before contacting USP.

## 401 FATS AND FIXED OILS

The following definitions and general procedures apply to fats, fixed oils, waxes, resins, balsams, and similar substances.

## PREPARATION OF SPECIMEN

If a specimen of oil shows turbidity owing to separated stearin, warm the container in a water bath at 50° until the oil is clear, or if the oil does not become clear on warming, pass it through dry filter paper in a funnel contained in a hot-water jacket. Mix thoroughly, and weigh at one time as many portions as are needed for the various determinations, using preferably a bottle having a pipet dropper, or a weighing buret. Keep the specimen melted, if solid at room temperature, until the desired portions of specimen are withdrawn.

## SPECIFIC GRAVITY

Determine the specific gravity of a fat or oil as directed under [Specific Gravity \(841\)](#).

## MELTING TEMPERATURE

Determine the melting temperature as directed for substances of Class II (see [Melting Range or Temperature \(741\)](#)).

## ACID VALUE (FREE FATTY ACIDS)

The acidity of fats and fixed oils in this Pharmacopeia may be expressed as the number of mL of 0.1 N alkali required to neutralize the free acids in 10.0 g of substance. Acidity is frequently expressed as the Acid Value, which is the number of mg of potassium hydroxide required to neutralize the free acids in 1.0 g of the substance. Unless otherwise directed in the individual monograph, use Method I.

## Method I

Procedure— Unless otherwise directed, dissolve about 10.0 g of the substance, accurately weighed, in 50 mL of a mixture of equal volumes of alcohol and ether (which has been neutralized to phenolphthalein with 0.1 N potassium hydroxide or 0.1 N sodium hydroxide, unless otherwise specified) contained in a flask. If the test specimen does not dissolve in the cold solvent, connect the flask with a suitable condenser and warm slowly, with frequent shaking, until the specimen dissolves. Add 1 mL of phenolphthalein TS, and titrate with 0.1 N potassium hydroxide VS or 0.1 N sodium hydroxide VS until the solution remains faintly pink after shaking for 30 seconds. Calculate either the Acid Value or the volume of 0.1 N alkali required to neutralize 10.0 g of specimen (free fatty acids), whichever is appropriate. Calculate the Acid Value by the formula:

$$56.11V \times N/W$$

in which 56.11 is the molecular weight of potassium hydroxide; V is the volume, in mL; N is the normality of the potassium hydroxide solution or the sodium hydroxide solution; and W is the weight, in g, of the sample taken.

If the volume of 0.1 N potassium hydroxide VS or 0.1 N sodium hydroxide VS required for the titration is less than 2 mL, a more dilute titrant may be used, or the sample size may be adjusted accordingly. The results may be expressed in terms of the volume of titrant used or in terms of the equivalent volume of 0.1 N potassium hydroxide or 0.1 N sodium hydroxide.

If the oil has been saturated with carbon dioxide for the purpose of preservation, gently reflux the alcohol-ether solution for 10 minutes before titration. The oil may be freed from carbon dioxide also by exposing it in a shallow dish in a vacuum desiccator for 24 hours before weighing the test specimens.

## Method II

Procedure— Prepare 125 mL of a solvent mixture consisting of equal volumes of isopropyl alcohol and toluene. Before use, add 2 mL of a 1% solution of phenolphthalein in isopropyl alcohol to the 125-mL mixture, and neutralize with alkali to a faint but permanent pink color. Weigh accurately the appropriate amount of well-mixed liquid sample indicated in the table below, and dissolve it in the neutralized solvent mixture. If the test specimen does not dissolve in the cold solvent, connect the flask with a suitable condenser and warm slowly, with frequent shaking, until the specimen dissolves. Shake vigorously while titrating with 0.1 N potassium hydroxide VS or 0.1 N sodium hydroxide VS to the first permanent pink of the same intensity as that of the neutralized solvent before mixing with the sample. Calculate the Acid Value as indicated in Method I.

Acid Value	Sample Weight (g)
0–1	20
1–4	10
4–15	2.5
15–74.9	0.5
≥75.0	0.1

## ESTER VALUE

The Ester Value is the number of mg of potassium hydroxide required to saponify the esters in 1.0 g of the substance. If the Saponification Value and the Acid Value have been determined, the difference between these two represents the Ester Value.

Procedure— Place 1.5 g to 2 g of the substance in a tared, 250-mL flask, weigh accurately, add 20 mL to 30 mL of neutralized alcohol, and shake. Add 1 mL of phenolphthalein TS, and titrate with 0.5 N alcoholic potassium hydroxide VS until the free acid is neutralized. Add 25.0 mL of 0.5 N alcoholic potassium hydroxide VS, and proceed as directed under Saponification Value, beginning with "Heat the flask" and omitting the further addition of phenolphthalein TS. The difference between the volumes, in mL, of 0.5 N hydrochloric acid consumed in the actual test and in the blank test, multiplied by 28.05 and divided by the weight in g of the specimen taken, is the Ester Value.

## HYDROXYL VALUE

The Hydroxyl Value is the number of mg of potassium hydroxide equivalent to the hydroxyl content of 1.0 g of the substance.

Pyridine–Acetic Anhydride Reagent— Just before use, mix 3 volumes of freshly opened or freshly distilled pyridine with 1 volume of freshly opened or freshly distilled acetic anhydride.

Procedure— Transfer a quantity of the substance, determined by reference to the [accompanying table](#) and accurately weighed, to a glass-stoppered, 250-mL conical flask, and add 5.0 mL of Pyridine–Acetic Anhydride Reagent. Transfer 5.0 mL of Pyridine–Acetic Anhydride Reagent to a second glass-stoppered, 250-mL conical flask to provide the reagent blank. Fit both flasks with suitable glass-jointed reflux condensers, heat on a steam bath for 1 hour, add 10 mL of water through each condenser, and heat on the steam bath for 10 minutes more. Cool, and to each add 25 mL of butyl alcohol, previously neutralized to phenolphthalein TS with 0.5 N alcoholic potassium hydroxide, by pouring 15 mL through each condenser and, after removing the condensers, washing the sides of both flasks with the remaining 10-mL portions. To each flask add 1 mL of phenolphthalein TS, and titrate with 0.5 N alcoholic potassium hydroxide VS, recording the volume, in mL, consumed by the residual acid in the test solution as T and that consumed by the blank as B. In a 125-mL conical flask, mix about 10 g of the substance, accurately weighed, with 10 mL of freshly distilled pyridine, previously neutralized to phenolphthalein TS, add 1 mL of phenolphthalein TS, and titrate with 0.5 N alcoholic potassium hydroxide VS, recording the volume, in mL, consumed by the free acid in the test specimen as A, or use the Acid Value to obtain A. Calculate the Hydroxyl Value taken by the formula:

$$(56.11N / W)[B + (WA / C) - T]$$

in which W and C are the weights, in g, of the substances taken for the acetylation and for the free acid determination, respectively; N is the exact normality of the alcoholic potassium hydroxide; and 56.11 is the molecular weight of potassium hydroxide.

Hydroxyl Value Range	Weight of Test Specimen, g
0 to 20	10
20 to 50	5
50 to 100	3
100 to 150	2
150 to 200	1.5
200 to 250	1.25
250 to 300	1.0
300 to 350	0.75

#### IODINE VALUE

The Iodine Value represents the number of g of iodine absorbed, under the prescribed conditions, by 100 g of the substance. Unless otherwise specified in the individual monograph, determine the Iodine Value by Method I.

##### Method I (Hanus Method)

Procedure— Transfer an accurately weighed quantity of sample, as determined from the accompanying table, into a 250-mL iodine flask, dissolve it in 10 mL of chloroform, add 25.0 mL of iodobromide TS, insert the stopper in the vessel securely, and allow it to stand for 30 minutes protected from light, with occasional shaking. Then add, in the order named, 30 mL of [potassium iodide TS](#) and 100 mL of water, and titrate the liberated iodine with 0.1 N sodium thiosulfate VS, shaking thoroughly after each addition of thiosulfate. When the iodine color becomes quite pale, add 3 mL of starch TS, and continue the titration with 0.1 N sodium thiosulfate VS until the blue color is discharged. Perform a blank test at the same time with the same quantities of the same reagents and in the same manner (see [Residual Titrations](#) 541). Calculate the Iodine Value from the formula:

$$[126.9(VB - VS)N] / 10W$$

in which 126.9 is the atomic weight of iodine; VB and VS are the volumes, in mL, of 0.1 N sodium thiosulfate VS consumed by the blank test and the actual test, respectively; N is the exact normality of the sodium thiosulfate VS; and W is the weight, in g, of the substance taken for the test. [note—If more than half of the iodobromide TS is absorbed by the portion of the substance taken, repeat the determination, using a smaller portion of the substance under examination.]

##### Sample Weights

Iodine value expected	Weight in g, $\pm 0.001$
<5	3.000
5–20	1.000
21–50	0.400
51–100	0.200
101–150	0.130
151–200	0.100

##### Method II

Potassium Iodide Solution— Dissolve 10.0 g of potassium iodide in water to make 100 mL. Store in light-resistant containers.

Starch Indicator Solution— Mix 1 g of soluble starch with sufficient cold water to make a thin paste. Add, while stirring, to 100 mL of boiling water. Mix, and cool. Use only the clear solution.

Procedure— Melt the sample, if it is not already liquid. [note—The temperature during melting should not exceed the melting point of the sample by more than  $10^{\circ}$ .] Pass through two pieces of filter paper to remove any solid impurities and the last traces of moisture. The filtration may be performed in an air oven at  $100^{\circ}$  but should be completed within 5 minutes  $\pm$  30 seconds. The sample must be absolutely dry. All glassware must be absolutely clean and completely dry. After filtration, allow the filtered sample to achieve a temperature of  $68^{\circ}$  to  $71 \pm 1^{\circ}$  before weighing the sample. Once the sample has achieved a temperature of  $68^{\circ}$  to  $71 \pm 1^{\circ}$ , immediately weigh the sample into a 500-mL iodine flask, using the weights and weighing accuracy noted in the accompanying table. [note—The weight of the substance must be such that there will be an excess of [iodochloride TS](#) of 50% to 60% of the amount added, that is, 100% to 150% of the amount absorbed.] Add 15 mL of a fresh mixture of cyclohexane and glacial acetic acid (1:1), and swirl to dissolve the sample. Add 25.0 mL of iodochloride TS, insert the stopper securely in the flask, and swirl to mix. Allow it to stand at  $25 \pm 5^{\circ}$ , protected from light, with occasional shaking, for 1.0 or 2.0 hours, depending on the Iodine Value (IV) of the sample: IV less than 150, 1.0 hour; IV equal to or greater than 150, 2.0 hours. Then, within 3 minutes after the indicated reaction time, add, in the order named, 20 mL of Potassium Iodide Solution and 150 mL of recently boiled and cooled water, and mix. Within 30 minutes, titrate the liberated iodine with 0.1 N sodium thiosulfate VS, while stirring by mechanical means after each addition of thiosulfate. When the yellow iodine color has almost disappeared, add 1 to 2 mL of Starch Indicator Solution, and continue the titration with 0.1 N sodium thiosulfate VS until the blue color is discharged. Perform a blank test at the same time with the same quantities of the same reagents and in the same manner (see [Residual Titrations](#) 541). The difference between the volumes, in mL, of 0.1 N sodium thiosulfate consumed by the blank test and the actual test, multiplied by 1.269 and divided by the weight, in g, of the sample taken, is the Iodine Value.

#### PEROXIDE VALUE

The Peroxide Value is the number that expresses, in milliequivalents of active oxygen, the quantity of peroxide contained in 1000 g of the substance. [note—This test must be performed promptly after sampling to avoid oxidation of the test specimen.]

Procedure— Unless otherwise directed, place about 5 g of the substance, accurately weighed, in a 250-mL conical flask fitted with a ground-glass stopper. Add 30 mL of a mixture of glacial acetic acid and chloroform (3:2), shake to dissolve, and add 0.5 mL of saturated potassium iodide solution. Shake for exactly 1 minute, and add 30 mL of water. Titrate with 0.01 N sodium thiosulfate VS, adding the titrant slowly with continuous shaking, until the yellow color is almost discharged. Add 5 mL of starch TS, and continue the titration, shaking vigorously, until the blue color is discharged. Perform a blank determination under the same conditions. [note—The volume of titrant used in the blank determination must not exceed 0.1 mL.] The difference between the volumes, in mL, of 0.01 N sodium thiosulfate consumed in the actual test and in the blank test, multiplied by 10 and divided by the weight, in g, of the specimen taken, is the Peroxide Value.

#### SAPONIFICATION VALUE

The Saponification Value is the number of mg of potassium hydroxide required to neutralize the free acids and saponify the esters contained in 1.0 g of the substance.

Procedure— Place 1.5 g to 2 g of the substance in a tared, 250-mL flask, weigh accurately, and add to it 25.0 mL of 0.5 N alcoholic potassium hydroxide. Heat the flask on a steam bath, under a suitable condenser to maintain reflux for 30 minutes, frequently rotating the contents. Then add 1 mL of phenolphthalein TS, and titrate the excess potassium hydroxide

with 0.5 N hydrochloric acid VS. Perform a blank determination under the same conditions (see Residual Titrations under [Titrimetry \(541\)](#)). The titration also can be carried out potentiometrically. The difference between the volumes, in mL, of 0.5 N hydrochloric acid consumed in the actual test and in the blank test, multiplied by 56.1 and the exact normality of the 0.5 N hydrochloric acid VS, and divided by the weight in g of specimen taken, is the Saponification Value.

If the oil has been saturated with carbon dioxide for the purpose of preservation, expose it in a shallow dish in a vacuum desiccator for 24 hours before weighing the test specimens.

#### UNSAPONIFIABLE MATTER

The term "Unsaponifiable Matter" in oils or fats, refers to those substances that are not saponifiable by alkali hydroxides but are soluble in the ordinary fat solvents, and to products of saponification that are soluble in such solvents.

Procedure— Transfer about 5.0 g of the oil or fat, accurately weighed, to a 250-mL conical flask, add 50 mL of an alcoholic potassium hydroxide solution prepared by dissolving 12 g of potassium hydroxide in 10 mL of water and diluting this solution with alcohol to 100 mL, and heat the flask on a steam bath under a suitable condenser to maintain reflux for 1 hour, swirling frequently. Cool to a temperature below 25°, and transfer the contents of the flask to a separator having a polytetrafluoroethylene stopcock, rinsing the flask with two 50-mL portions of water that are added to the separator (do not use grease on stopcock). Extract with three 100-mL portions of ether, combining the ether extracts in another separator containing 40 mL of water. Gently rotate or shake the separator for a few minutes. [note—Violent agitation may result in the formation of a difficult-to-separate emulsion.] Allow the mixture to separate, and discard the lower aqueous phase. Wash the ether extract with two additional 40-mL portions of water, and discard the lower aqueous phase. Wash the ether extract successively with a 40-mL portion of potassium hydroxide solution (3 in 100) and a 40-mL portion of water. Repeat this potassium hydroxide solution-water wash sequence three times. Wash the ether extract with 40-mL portions of water until the last washing is not reddened by the addition of 2 drops of phenolphthalein TS. Transfer the ether extract to a tared flask, and rinse the separator with 10 mL of ether, adding the rinsings to the flask. Evaporate the ether on a steam bath, and add 6 mL of acetone to the residue. Remove the acetone in a current of air, and dry the residue at 105° until successive weighings differ by not more than 1 mg. Calculate the percentage of unsaponifiable matter in the portion of oil or fat taken by the formula:

$$100(\text{WR} / \text{WS})$$

in which WR is the weight, in g, of the residue; and WS is the weight, in g, of the oil or fat taken for the test.

Dissolve the residue in 20 mL of alcohol, previously neutralized to the phenolphthalein endpoint, add phenolphthalein TS, and titrate with 0.1 N alcoholic sodium hydroxide VS to the first appearance of a faint pink color that persists for not less than 30 seconds. If the volume of 0.1 N alcoholic sodium hydroxide required is greater than 0.2 mL, the separation of the layers was incomplete; the residue weighed cannot be considered as "unsaponifiable matter," and the test must be repeated.

#### SOLIDIFICATION TEMPERATURE OF FATTY ACIDS

Preparation of the Fatty Acids— Heat 75 mL of glycerin–potassium hydroxide solution (made by dissolving 25 g of potassium hydroxide in 100 mL of glycerin) in an 800-mL beaker to 150°, and add 50 mL of the clarified fat, melted if necessary. Heat the mixture for 15 minutes with frequent stirring, but do not allow the temperature to rise above 150°. Saponification is complete when the mixture is homogeneous, with no particles clinging to the beaker at the meniscus. Pour the contents of the beaker into 500 mL of nearly boiling water in an 800-mL beaker or casserole, add slowly 50 mL of dilute sulfuric acid (made by adding water and sulfuric acid (3:1)), and heat the solution, with frequent stirring, until the fatty acids separate cleanly as a transparent layer. Wash the acids with boiling water until free from sulfuric acid, collect them in a small beaker, place on a steam bath until the water has settled and the fatty acids are clear, filter into a dry beaker while hot, and dry at 105° for 20 minutes. Place the warm fatty acids in a suitable container, and cool in an ice bath until they congeal.

Test for Complete Saponification— Place 3 mL of the dry acids in a test tube, and add 15 mL of alcohol. Heat the solution to boiling, and add an equal volume of 6 N ammonium hydroxide. A clear solution results.

Procedure— Using an apparatus similar to the "Congealing Temperature Apparatus" specified therein, proceed as directed for Procedure under [Congealing Temperature \(651\)](#), reading "solidification temperature" for "congealing point" (the terms are synonymous). The average of not less than four consecutive readings of the highest point to which the temperature rises is the solidification temperature of the fatty acids.

#### FATTY ACID COMPOSITION

Standard Solution— Prepare an ester mixture of known composition containing the esters required in the individual monograph. This Standard Solution may contain other components. [note—Ester mixtures are available commercially from Nu-Chek-Prep, Inc., P.O. Box 295, Elysian, MN 56028. Typical Nu-Chek-Prep ester mixtures useful in this test include Nu-Chek

17A and Nu-Chek 19A.] Nu-Chek mixture 17A has the following composition:

Percentage	Fatty Acid Ester	Carbon-chain Length	No. of Double Bonds
1.0	methyl myristate	14	0
4.0	methyl palmitate	16	0
3.0	methyl stearate	18	0
3.0	methyl arachidate	20	0
3.0	methyl behenate	22	0
3.0	methyl lignocerate	24	0
45.0	methyl oleate	18	1
15.0	methyl linoleate	18	2
3.0	methyl linolenate	18	3
20.0	methyl erucate	22	1

Nu-Chek mixture 19A has the following composition:

Percentage	Fatty Acid Ester	Carbon-chain Length	No. of Double Bonds
7.0	methyl caprylate	8	0
5.0	methyl caprate	10	0
48.0	methyl laurate	12	0
15.0	methyl myristate	14	0
7.0	methyl palmitate	16	0
3.0	methyl stearate	18	0
12.0	methyl oleate	18	1
3.0	methyl linoleate	18	2

Test Solution— [note—If fatty acids containing more than 2 double bonds are present in the test specimen, remove air from the flask by purging it with nitrogen for a few minutes.] Transfer about 100 mg of the test specimen to a 50-mL conical flask fitted with a suitable water-cooled reflux condenser and a magnetic stir bar. Add 4 mL of 0.5 N methanolic sodium

oxide solution, and reflux until fat globules disappear (usually 5 to 10 minutes). Add 5 mL of a solution prepared by dissolving 14 g of boron trifluoride in methanol to make 100 mL. Swirl to mix, and reflux for 2 minutes. Add 4 mL of chromatographic n-heptane through the condenser, and reflux for 1 minute. Cool, remove the condenser, add about 15 mL of saturated sodium chloride solution, shake, and allow the layers to separate. Pass the n-heptane layer through 0.1 g of anhydrous sodium sulfate (previously washed with chromatographic n-heptane) into a suitable flask. Transfer 1.0 mL of this solution to a 10-mL volumetric flask, dilute with chromatographic n-heptane to volume, and mix.

**System Suitability Solution**— Transfer about 20 mg each of stearic acid, palmitic acid and oleic acid to a 25-mL conical flask fitted with a suitable water-cooled reflux condenser and a magnetic stir bar, and proceed as directed for **Test Solution**, beginning with “Add 5.0 mL of a solution prepared by dissolving.”

**Chromatographic System** (see [Chromatography \(621\)](#))— The gas chromatograph is equipped with a flame-ionization detector, maintained at a temperature of about 260°, a splitless injection system, and a 0.53-mm × 30-m fused-silica capillary column bonded with a 1.0-μm layer of phase G16. The chromatograph is programmed to maintain the column temperature at 70° for about 2 minutes after injection, then to increase the temperature at the rate of 5° per minute to 240°, and finally to maintain this temperature for 5 minutes. The injection port temperature is maintained at about 220°. The carrier gas is helium with a linear velocity of about 50 cm per second.

Chromatograph the **System Suitability Solution**, and record the peak responses as directed for **Procedure**: the relative retention times are about 0.87 for methyl palmitate, 0.99 for methyl stearate, and 1.0 for methyl oleate; the resolution, R, between methyl stearate and methyl oleate is not less than 1.5; and the relative standard deviation of the peak area responses for the palmitate and stearate peaks for replicate injections is not more than 6.0%. The relative standard deviation of the peak area response ratio of the palmitate to stearate peaks from these replicate injections is not more than 1.0%.

**Procedure**— Separately inject equal volumes (about 1 μL) of the **Standard Solution** and the **Test Solution** into the chromatograph, record the chromatograms, identify the fatty acid ester peaks in the chromatogram of the **Test Solution** by comparing the retention times of these peaks with those obtained in the chromatogram of the **Standard Solution**, and measure the peak areas for all of the fatty acid ester peaks in the chromatogram obtained from the **Test Solution**. Calculate the percentage of each fatty acid component in the test specimen by the formula:

$$100(A/B)$$

in which A is the area of the peak response obtained for each individual fatty acid ester component; and B is the sum of the peak areas of all of the peaks, excluding the solvent peak, in the chromatogram obtained from the **Test Solution**.

#### WATER AND SEDIMENT IN FIXED OILS

**Apparatus**— The preferred centrifuge has a diameter of swing (d = distance from tip to tip of whirling tubes) of 38 to 43 cm and is operated at a speed of about 1500 rpm. If a centrifuge of different dimensions is used, calculate the desired rate of revolution by the formula:

$$\text{rpm} = 1500 \sqrt{40.6/d}$$

The centrifuge tubes are pear-shaped, and are shaped to accept closures. The total capacity of each tube is about 125 mL. The graduations are clear and distinct, reading upward from the bottom of the tube according to the scale shown in the [accompanying table](#).

Volume (mL)	Scale Division (mL)
0 to 3	0.1
3 to 5	0.5
5 to 10	1.0
10 to 25	5.0
25 to 50	25.0
50 to 100	50.0

**Procedure**— Place 50.0 mL of benzene in each of two centrifuge tubes, and to each tube add 50.0 mL of the oil, warmed if necessary to re-incorporate separated stearin, and mixed thoroughly at 25°. Insert the stopper tightly into the tubes, and shake them vigorously until the contents are mixed thoroughly, then immerse the tubes in a water bath at 50° for 10 minutes. Centrifuge for 10 minutes. Read the combined volume of water and sediment at the bottom of each tube. Centrifuge repeatedly for 10-minute periods until the combined volume of water and sediment remains constant for 3 consecutive readings. The sum of the volumes of combined water and sediment in the two tubes represents the percentage, by volume, of water and sediment in the oil.

#### ANISIDINE VALUE

The anisidine value is defined as 100 times the optical density measured in a 1-cm cell of a solution containing 1 g of the substance to be examined in 100 mL of a mixture of solvents and reagents according to the method described below. [note—Carry out the operations as rapidly as possible, avoiding exposure to actinic light.]

**Test Solution A**— Dissolve 0.500 g of the substance to be examined in isooctane, and dilute with the same solvent to 25.0 mL.

**Test Solution B**— To 5.0 mL of **Test Solution A** add 1.0 mL of a 2.5 g per L solution of p-anisidine in glacial acetic acid, shake, and store protected from light.

**Standard Solution**— To 5.0 mL of isooctane add 1.0 mL of a 2.5 g per L solution of p-anisidine in glacial acetic acid, shake, and store protected from light.

**Procedure**— Measure the absorbance of **Test Solution A** at 350 nm using isooctane as the blank. Measure the absorbance of **Test Solution B** at 350 nm exactly 10 minutes after its preparation, using the **Standard Solution** as the compensation liquid. Calculate the Anisidine Value from the expression:

$$\frac{25(1.2A_s - A_b)}{m}$$

in which As is the absorbance of **Test Solution B** at 350 nm; Ab is the absorbance of **Test Solution A** at 350 nm; and m is the weight, in g, of the substance to be examined in **Test Solution A**.

#### TOTAL OXIDATION VALUE (TOTOX)

Total Oxidation Value is defined by the formula:

$$2PV + AV$$

in which PV is the Peroxide Value, and AV is the Anisidine Value.

Auxiliary Information— Please [check for your question in the FAQs](#) before contacting USP.

## 411 FOLIC ACID ASSAY

The following procedure is provided for the estimation of folic acid as an ingredient of Pharmacopeial preparations containing other active constituents.

[USP Reference Standards](#) 11 — [USP Folic Acid RS](#).

Mobile Phase— Place 2.0 g of monobasic potassium phosphate in a 1-liter volumetric flask, and dissolve in about 650 mL of water. Add 12.0 mL of a 1 in 4 solution of tetrabutylammonium hydroxide in methanol, 7.0 mL of 3 N phosphoric acid, and 240 mL of methanol. Cool to room temperature, adjust with either 3 N phosphoric acid or 6 N ammonium hydroxide to a pH of 7.0, dilute with water to volume, and mix. Pass through a 0.45- $\mu$ m filter, and recheck the pH before use. [note—The methanol-to-water ratio may be varied by up to 3 percent and the pH may be increased up to 7.15 to achieve better separation.]

Diluting Solvent— Prepare as directed under Mobile Phase. Adjust to a pH of 7.0, and bubble nitrogen through the solution for 30 minutes before use.

Internal Standard Solution— Dissolve about 25 mg of methylparaben in 2.0 mL of methanol, dilute with Diluting Solvent to 50 mL, and mix.

Standard Folic Acid Solution— Transfer about 12 mg of [USP Folic Acid RS](#), accurately weighed, to a low-actinic, 50-mL volumetric flask, dissolve in 2 mL of ammonium hydroxide, dilute with Diluting Solvent to volume, and mix.

Standard Preparation— Transfer 2.0 mL of Standard Folic Acid Solution to a low-actinic, 25-mL volumetric flask, add 2.0 mL of Internal Standard Solution, add Diluting Solvent to volume, and mix.

Assay Preparation— Transfer an accurately weighed or measured portion of the preparation to be assayed, containing about 1 mg of folic acid, to a low-actinic, 50-mL volumetric flask, add 4.0 mL of Internal Standard Solution, add Diluting Solvent to volume, and mix.

Chromatographic System (see [Chromatography](#) 621)— The liquid chromatograph is equipped with a 280-nm detector and a 15-cm  $\times$  3.9-mm column that contains packing L1. The flow rate is about 1.0 mL per minute. Chromatograph the Standard Preparation, and record the peak responses as directed for Procedure: there is baseline separation of folic acid and methylparaben.

Procedure— Separately inject equal volumes (about 10  $\mu$ L) of Standard Preparation and Assay Preparation into the chromatograph, record the chromatograms, and measure the responses for the major peaks. The relative retention times are about 0.8 for folic acid and 1.0 for methylparaben. Calculate the quantity, in  $\mu$ g, of C19H19N7O6 in the portion of the preparation taken by the formula:

$$50C(RU / RS)$$

in which C is the concentration, in  $\mu$ g per mL, of USP Folic Acid RS in the Standard Preparation; and RU and RS are the ratios of the response of the folic acid peak to that of the methylparaben peak obtained from the Assay Preparation and the Standard Preparation, respectively.

Auxiliary Information— Please [check for your question in the FAQs](#) before contacting USP.

## 425 IODOMETRIC ASSAY—ANTIBIOTICS

The following method is provided for the assay of most of the Pharmacopeial penicillin antibiotic drugs and their dosage forms, for which iodometric titration is particularly suitable.

Standard Preparation— Dissolve in the solvent specified in the table of Solvents and Final Concentrations a suitable quantity of the USP Reference Standard specified in the individual monograph, previously dried under the conditions specified in the individual monograph and accurately weighed, and dilute quantitatively and stepwise with the same solvent to obtain a solution having a known concentration of about that specified in the table. Pipet 2.0 mL of this solution into each of two 125-mL glass-stoppered conical flasks.

## Solvents and Final Concentrations

Antibiotic	Solvent*	Final Concentration
Amoxicillin	Water	1.0 mg per mL
Ampicillin	Water	1.25 mg per mL
Ampicillin Sodium	Buffer No. 1	1.25 mg per mL
Cloxacillin Sodium	Water	1.25 mg per mL
Cyclacillin	Water	1.0 mg per mL
Dicloxacillin Sodium	Buffer No. 1	1.25 mg per mL

Penicillin Sodium	Buffer No. 1	1.25 mg per mL
Nafcillin Sodium	Buffer No. 1	1.25 mg per mL
Oxacillin Sodium	Buffer No. 1	1.25 mg per mL
Penicillin G Potassium	Buffer No. 1	2,000 units per mL
Penicillin G Sodium	Buffer No. 1	2,000 units per mL
Penicillin V Potassium	Buffer No. 1	2,000 units per mL
Phenethicillin Potassium	Buffer No. 1	2,000 units per mL

\* Unless otherwise noted, the Buffers are the potassium phosphate buffers defined in the section Media and Diluents under [Antibiotics—Microbial Assays](#) 81, except that sterilization is not required before use.

**Assay Preparation**— Unless otherwise specified in the individual monograph, dissolve in the solvent specified in the table of Solvents and Final Concentrations a suitable quantity, accurately weighed, of the specimen under test, and dilute quantitatively with the same solvent to obtain a solution having a known final concentration of about that specified in the table. Pipet 2 mL of this solution into each of two 125-mL glass-stoppered conical flasks.

#### Procedure—

**Inactivation and Titration**— To 2.0 mL of the Standard Preparation and of the Assay Preparation, in respective flasks, add 2.0 mL of 1.0 N sodium hydroxide, mix by swirling, and allow to stand for 15 minutes. To each flask add 2.0 mL of 1.2 N hydrochloric acid, add 10.0 mL of 0.01 N iodine VS, immediately insert the stopper, and allow to stand for 15 minutes. Titrate with 0.01 N sodium thiosulfate VS. As the endpoint is approached, add 1 drop of [starch iodide paste TS](#), and continue the titration to the discharge of the blue color.

**Blank Determination**— To a flask containing 2.0 mL of the Standard Preparation add 10.0 mL of 0.01 N iodine VS. If the Standard Preparation contains amoxicillin or ampicillin, immediately add 0.1 mL of 1.2 N hydrochloric acid. Immediately titrate with 0.01 N sodium thiosulfate VS. As the endpoint is approached, add 1 drop of [starch iodide paste TS](#), and continue the titration to the discharge of the blue color. Similarly treat a flask containing 2.0 mL of the Assay Preparation.

**Calculations**— Calculate the microgram (or unit) equivalent (F) of each mL of 0.01 N sodium thiosulfate consumed by the Standard Preparation by the formula:

$$(2CP) / (B - I)$$

in which C is the concentration, in mg per mL, of Reference Standard in the Standard Preparation, P is the potency, in  $\mu$ g (or units) per mg, of the Reference Standard, B is the volume, in mL, of 0.01 N sodium thiosulfate consumed in the Blank determination, and I is the volume, in mL, of 0.01 N sodium thiosulfate consumed in the Inactivation and titration. Calculate the potency of the specimen under test by the formula given in the individual monograph.

**Auxiliary Information**— Please [check for your question in the FAQs](#) before contacting USP.

#### 429 LIGHT DIFFRACTION MEASUREMENT OF PARTICLE SIZE

Light diffraction is one of the most widely used techniques for measuring the size of a wide range of particles from very fine to very coarse. The method is popular because it is quick and easy to use, flexible, and it can be adapted to measure samples presented in various physical forms. The method depends on the analysis of the diffraction pattern produced when particles are exposed to a collimated beam of light. As the patterns are characteristic of the particle size, mathematical analysis can produce an accurate, repeatable picture of the size distribution.

This chapter provides guidance on the measurement of size distributions of particles in any phase system (e.g., powders, sprays, aerosols, suspensions, emulsions, and gas bubbles in liquids) through analysis of their angular light-scattering patterns. Traditionally, the measurement of particle size using laser diffraction has been limited to particles in the range 0.1  $\mu$ m to 3 mm. Due to recent advances in optics and lens and equipment design and construction, newer instruments are routinely capable of exceeding this range (e.g., 0.1  $\mu$ m to 8 mm). It is the responsibility of the user to demonstrate the applicability of the instrument for its intended use and to validate any method prior to its adoption for routine use.

For nonspherical particles, an equivalent-sphere size distribution is obtained because the technique uses the assumption of spherical particles in its optical model. The resulting particle size distribution may be different from those obtained by methods based on other physical principles (such as sedimentation or sieving). The laser diffraction technique cannot distinguish between scattering by single particles and scattering by clusters of primary particles forming an agglomerate or an aggregate. If the presence of aggregates is suspected, this can be investigated using other techniques such as microscopy.

The laser diffraction technique is based on the phenomenon that particles scatter light in all directions with an intensity pattern that is dependent on particle size. All present instruments assume a spherical shape for the particles. Historically, the early laser diffraction instruments used only scattering at small angles and, thus, has been known by the following names: Fraunhofer diffraction, (near-) forward light scattering, and low-angle laser light scattering (LALLS).

However, the technique since has been broadened to include light scattering in a wider angular range by application of the Mie theory, in addition to the Fraunhofer approximation and anomalous diffraction.

The measurement of particle size is an important aspect in the characterization of raw materials and drug formulations. To monitor production and particle stability, efficient and rapid methods for particle sizing are needed. The electronic measurement of samples offers a convenient solution to this problem. However, the electronic measurement will often have to be accompanied by microscopical investigation to determine the type of particles being investigated. Modern drug formulations may also be particulate formulations where the particle size will be below 100  $\mu$ m, and reliable and reproducible methods are needed for the quality control of these drug products.

#### PRINCIPLE

A representative sample, dispersed at an adequate concentration in a suitable liquid or gas, is passed through the beam of a monochromatic light source, usually from a laser. The light scattered by the particles at various angles is measured by a multi-element detector, and numerical values relating to the scattering pattern are then recorded for subsequent analysis. These numerical scattering values are then transformed, using an appropriate optical model and mathematical procedure, to yield the proportion of total volume to a discrete number of size classes forming a volumetric particle size distribution (e.g., x50 describes a particle diameter corresponding to 50% of the cumulative undersize distribution).

#### APPARATUS

A typical setup for a laser diffraction instrument is shown in [Figure 1](#).

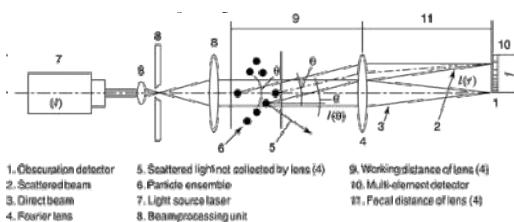

Fig. 1. Typical setup for a laser diffraction instrument.

A representative sample, dispersed at an adequate concentration, is passed through the light beam in a measuring zone by a transporting fluid (gas or liquid); this measuring zone should be within the working distance of the lens used. In some cases the particle stream in a process is illuminated directly by the laser beam for measurement, as in the case of sprays, aerosols, and air bubbles in liquids. In other cases (such as emulsions, pastes, and powders), representative samples can be dispersed in suitable liquids. Often dispersants (such as wetting agents or stabilizers) or mechanical forces (such as agitation or ultrasonication), or both, are applied to deagglomerate particles and to stabilize the dispersion. For these liquid dispersions, a recirculating system is most commonly used, consisting of an optical measurement cell, a dispersion bath (usually equipped with stirrer and ultrasonic elements), a pump, and tubing.

Dry powders can also be converted into aerosols through the use of dry powder dispersers, which apply mechanical forces for deagglomeration. In this case, a dosing device feeds the disperser with a constant mass flow of sample. The disperser uses the energy of compressed gas or the differential pressure to a vacuum to disperse the particles. It outputs an aerosol that is blown through the measuring zone, usually into the inlet of a vacuum pipe that collects the particles.

There are two positions in which the particles can enter the laser beam. In the conventional case, the particles enter the parallel beam before and within the working distance of the collecting lens. In the so-called reversed Fourier optics case, the particles enter behind the collecting lens, and thus in a converging beam.

The advantage of the conventional setup is that a reasonable path length for the sample is allowed within the working distance of the lens. The second setup allows only small path lengths but enables measurement of scattered light at larger angles, which is useful when submicron particles are present.

The interaction of the incident light beam with the dispersed particles results in a scattering pattern with different light intensities at various angles. The total angular intensity distribution, consisting of both direct and scattered light, is then focused by a positive lens or an assembly of lenses onto a multi-element detector. The lens(es) provide(s) for a scattering pattern which, within limits, is not dependent upon the location of the particles in the light beam. Thus the continuous angular intensity distribution is converted into a discrete spatial intensity distribution on a set of detector elements.

It is assumed that the recorded scattering pattern of the particle ensemble is identical to the sum of the patterns from all individual single scattering particles presented in random relative positions. Note that only a limited angular range of scattered light is collected by the lens(es), and thus by the detector.

#### PREPARATION OF THE SAMPLE

Prepare a representative sample of suitable volume for the measurement by an adequate sample splitting technique.

Sprays, aerosols, and gas bubbles in liquid should be measured directly, provided that their concentration is at an appropriate level, since sampling or dilution is generally impossible without altering the particle size distribution.

The dispersion procedure is adjusted to the purpose of the measurement: for example, whether agglomerates should be detected or broken down to primary particles.

For the development of a method, it is necessary to check that comminution of the primary particles does not occur, and conversely that a good dispersion of the agglomerates has been achieved. The dry particles may be examined microscopically before and after the addition and dispersion of aliquots of the dispersing liquid to determine if the particle size has changed, and if the agglomerates are dispersed but the primary particles are not fractured. The effect of the dispersion process can usually be checked by changing the dispersing energy and monitoring the change of the size distribution. The measured size distribution does not change significantly if the sample is well dispersed and the particles are neither fragile nor soluble. Microscopy may also be used to investigate primary particle comminution and adequacy of dispersion.

#### Dispersion Liquids

A variety of liquids are available for the dispersion of powders and must have the following characteristics:

- be transparent at the laser wavelength and free from air bubbles or other particles,
- be compatible with the materials used in the instrument (O-ring, tubing, etc.),
- not dissolve or alter the size of the particulate materials,
- favor easy and stable dispersion of the particulate material,
- have suitable viscosity to enable calculation,
- have a refractive index that differs from that of the material (for the Mie calculation), and
- not be hazardous to health and meet safety requirements.

A low-foaming surfactant and dispersant may be used to facilitate the wetting of the particles and to stabilize the dispersion. A preliminary check on the dispersion quality can be made by visual or microscopic inspection of the suspension.

If very small samples are required, it is also possible to take fractional samples out of a well-mixed sample paste if the material is neither fragile nor soluble. The consistency of the paste then prevents segregation errors. The pastes are formed by adding dispersant to the sample dropwise, while mixing it with a spatula. As long as the mixture forms lumps, single drops should be added while continuing the mixing after each drop. A good consistency for the paste is one like honey or toothpaste. If the paste becomes too fluid by mistake, it cannot be used, and a new preparation is initiated.

Alternatively, a concentrated suspension may be prepared. While stirring this concentrated suspension, a small aliquot is removed and transferred to the optical measurement cell containing the blank dispersing medium. Care must be taken to ensure the complete transfer of the sample and that settling of the larger particles does not occur.

Where a dispersant that does not dissolve the particles cannot be found, it may be possible to use a prefiltered, saturated solution of the sample in the dispersing solvent as the dispersant. Such a saturated solution may be produced by stirring an excess of sample in the dispersing solvent for several hours. For weak acids and weak bases, buffering of the dispersing solvent at low or high pH, respectively, can assist in identifying a suitable dispersant. The saturated medium is filtered using a membrane filter to remove any undissolved sample before use. This approach is not suitable if the sample forms a more viscous concentrated solution.

#### Dispersion Gases

For dry dispersion and spray applications, a compressed gas is sometimes used. If used, it is essential that it is free from oil, water, and particles. To achieve this, a dryer with a filter is required. Any vacuum unit is located away from the measurement zone, so that the output of the hot air does not reach the measuring zone. Avoid drafts in order to avoid unstable particulate streams.

#### Concentration

The particle concentration in the dispersion should be above a minimum level, which for many instruments will correspond to about 5% obscuration, in order to produce an acceptable signal-to-noise ratio in the detector. Likewise, it should be below a maximum level in order to avoid multiple scattering (for example, 35% above 20  $\mu\text{m}$  and 15% below 20  $\mu\text{m}$ ).

The optimum concentration is influenced by the laser beam width, the path length of the measurement zone, the optical properties of the particles, and the sensitivity of the detector elements. In view of the above, perform measurements at different particle concentrations in order to decide on the optimum concentration range that achieves the required

obscuration for any typical sample of material.

## MEASUREMENT

### Setting Up the Instrument and Blank Measurement

After selection of the appropriate particle size range and proper alignment of the optical part of the instrument, a blank measurement is performed in which a particle-free dispersion medium is used.

### Measurement of the Scattering of Dispersed Sample(s)

Generally, a large number of detector scans or sweeps at short time intervals is used (typically some 2 seconds or 1000 sweeps). For each detector element an average signal is calculated, sometimes together with its standard deviation. Data are stored in the computer memory. The magnitude of the signal from each detector element depends upon the detection area, the light intensity, and the quantum efficiency. The coordinates (size and position) of the detector elements, together with the focal distance of the lens, determine the region of scattering angles for each element. These factors are factory-determined and stored in the computer.

Most instruments also measure the intensity of the central laser beam. The difference between a dispersed sample and a blank experiment is given as an obscuration value, which is indicative of the total amount of scattering light and the particle concentration.

### Selection of an Appropriate Optical Model

Most often either the Fraunhofer approximation or the Mie theory is used, though other approximations are sometimes applied for calculation of the scattering matrix. Below approximately 25  $\mu\text{m}$ , the differences between the optical models become more significant. In this size range, the proper application of the Mie theory (assuming accurate real and imaginary refractive index values) provides the greatest accuracy. When using the Mie theory, the refractive indices of particulate and medium, or their ratio, are entered into the instrument to allow calculation of the model matrix. Often, small values of the imaginary part of the refractive index (about 0.01–0.1) are applied to cope with the surface roughness of the particles.<sup>4</sup> In order to obtain traceable results, it is essential that the refractive index values used are reported.

### Conversion of Scattering Pattern into Particle Size Distribution

This deconvolution step is the inverse of the calculation of a scattering pattern for a given particle size distribution. The fact that rapidly measured data always contain some random and systematic errors may cause erroneous size distribution results. Several mathematical procedures have been developed for use in the different instruments available. They allow for some weighting of deviations between measured and calculated scattering patterns (such as least squares), some constraints (such as non-negativity for amounts of particles), or (or in combination with) some smoothing of the size distribution curve. A new procedure uses the observed fluctuations of the detector signals to introduce proper weighting of these data and to calculate confidence intervals for the particle size distribution.

The algorithms used are specific to each make and model of equipment and are proprietary. The differences in the algorithms between different instruments can give rise to differences in the particle size statistics. For this reason, when reporting the particle size distribution and statistics for a given material, also report the cell type, sample state and preparation, together with the make and model of the equipment.

### Replicates

The required precision of the method is dependent on the characteristics of the material (milled versus not milled, robust versus fragile), and also on the requirements of the application (formulation type and technique). Appropriate measurement conditions are established experimentally, in relation to the desired precision. In general, at least three different representative samples from the same batch are measured. The repeatability of the particle size distribution parameter is as follows: for any central value of the distribution, for example the median ( $x_{50}$ ), the coefficient of variation is less than 10%. For values away from the center of the distribution, for example  $x_{10}$  and  $x_{90}$ , the coefficient of variation cannot exceed 15%. Below 10  $\mu\text{m}$ , these maximum values are doubled.

### System Suitability

The system suitability test is used to verify that the precision and accuracy are adequate for the analysis to be done. The test is based on the concept that the equipment, electronics, and analytical operations constitute an integral system that can be evaluated as such. This can be done by measuring at regular time intervals a control material of known size distribution. In general, unless otherwise specified in the individual monograph, the mean values of three measurements must deviate from the established value by less than 10% for  $x_{50}$ , and by less than 15% for  $x_{10}$  and  $x_{90}$ . Below 10  $\mu\text{m}$ , these maximum values are doubled.

### Reporting of Results

The distribution statistics are usually reported by the instrument data system. Most common parameters are calculated from the cumulative distribution by interpolation. Percentile sizes,  $x_m$ , represent the particle size in relation to which  $m$  percent of the distribution is smaller. (The notation  $d_m$  is also used and is equivalent to  $x_m$ .)  $Q_y$  represents the percent smaller than  $y$  microns. Mean sizes, such as  $D_{4,3}$ , the arithmetic volume mean diameter, can also be calculated by representing the distribution as a collection of spherical particles with diameters of the size band midpoints. Unless otherwise stated, parameters are calculated on the volume or mass basis.

## QUALIFICATION

### Calibration

Laser diffraction systems are based on the direct measurement of the diffraction pattern of particles, but with idealized properties of the particles. Thus, calibration in the strict sense is not required. However, it is still necessary and desirable to confirm the correct operation of the instrument with a qualification procedure.

### Accuracy and Repeatability

Primarily, qualification validation can be made with any certified or standard reference material, acceptable for use in the particular industry. Here, the total measurement procedure is being examined, including sampling, sample dispersion, sample transport through the measuring zone, measurement, and the deconvolution procedure. It is essential that the total operational procedure is adequately described in full detail.

Certified or standard reference materials consisting of a known distribution having a range of spherical particles over one decade of size are preferred. They are certified to mass percentage by an absolute technique, if available, and used in conjunction with an agreed, detailed operational procedure. It is essential that the real and imaginary part of the complex refractive index are precisely specified for the material if the Mie theory is applied in data analysis.

The response of a laser diffraction instrument is considered adequate if the mean value of  $x_{50}$  obtained from at least three independent measurements does not exceed the certified range of values of the certified or standard reference material by more than 3%. The mean values for  $x_{10}$  and  $x_{90}$  must not exceed the certified range of values by more than 5%. For repeatability, the coefficient of variation must be less than 3% for  $x_{50}$  and less than 5% for  $x_{10}$  and  $x_{90}$ . Below 10  $\mu\text{m}$ , these maximum values are doubled.

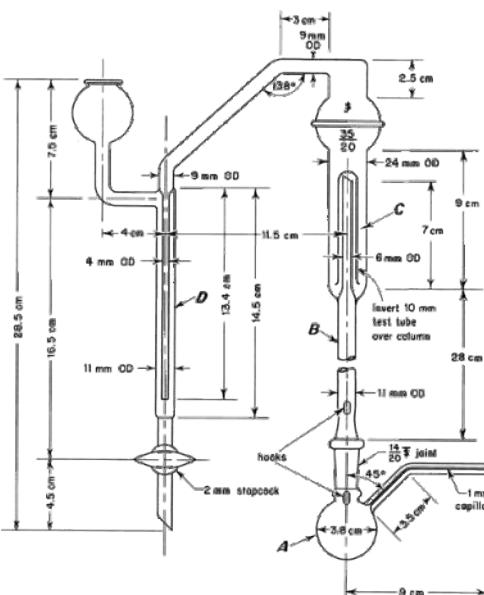

Although the use of spherical materials is preferable, nonspherical ones may also be used. Preferably, these have certified or typical values coming from laser diffraction analyses according to an agreed, detailed operational procedure. If the reference values come from methods other than laser diffraction, a significant bias may result. The reason for this bias is that the different principles applied in the various methods may lead to different responses to the particles, and thus to different equivalent-sphere diameters for the same nonspherical particle.

1 Small differences in the assumed complex refractive index may cause significant differences in the resulting particle size distributions.

Auxiliary Information— Please [check for your question in the FAQs](#) before contacting USP.

Topic/Question	Contact	Expert Committee
----------------	---------	------------------

Apparatus— The apparatus for methoxy determination is shown diagrammatically in the [accompanying figure](#).

#### Apparatus for Methoxy Determination

The boiling flask, A, is fitted with a capillary side-arm for the introduction of carbon dioxide or nitrogen and is connected to a column, B, which serves to separate aqueous hydriodic acid from the more volatile methyl iodide. The methyl iodide passes through water in a scrubber trap, C, and is finally absorbed in the bromine–acetic acid solution in absorption tube D. The carbon dioxide or nitrogen is introduced through a pressure-regulating device and connected to the apparatus by a small capillary containing a small cotton pledge. [note— Avoid the use of organic solvents in cleaning this apparatus, since traces remaining may interfere with the determination. This test is used also for ethoxy determination with an 80-minute reaction time and a titrant equivalent of 0.751 mg of (OC<sub>2</sub>H<sub>5</sub>).]

For greater convenience in use and cleaning, a ground-glass ball joint connects the two upright columns of the apparatus. The top of the scrubber C consists of a 35/20 ball joint, the upper half of which is connected to the side-arm leading into tube D. This permits taking the apparatus apart and facilitates adding the water to the trap. Also, it allows access to the loose inverted (10-mm) test tube that serves as the trap over the inner tube of the scrubber C.

#### Reagents—

bromine-acetic acid solution— Dissolve 100 g of potassium acetate in 1000 mL of a solution consisting of 900 mL of glacial acetic acid and 100 mL of acetic anhydride. On the day of use, to 145 mL of this solution add 5 mL of bromine.

hydriodic acid— A colorless, or nearly colorless, constant-boiling reagent solution, prepared for this purpose, is available commercially. If not obtained commercially, it may be prepared by distilling hydriodic acid over red phosphorus, passing carbon dioxide or nitrogen through the apparatus during the distillation. Use the constant-boiling mixture (between 55% and 58% of HI) distilling between 126° and 127°, which is colorless or nearly colorless. [Caution—Exercise safety precautions when distilling Hydriodic Acid. ] Place the acid in small, amber, glass-stoppered bottles previously flushed with carbon dioxide, or nitrogen, seal with paraffin, and store in a cool, dark place.

Procedure— Prepare the apparatus by disconnecting the ball joint and pouring water into trap C until it is half-full. Connect the two parts, using a minimal amount of a suitable silicone grease to seal the ball joint. Add 7 mL of Bromine-Acetic Acid Solution to absorption tube D. Weigh the sample in a tared gelatin capsule, and add it to the boiling flask along with a few boiling chips or pieces of porous plate. Finally add 6 mL of Hydriodic Acid and attach the flask to the column, using a minimal amount of a suitable silicone grease to seal the junction. Bubble the carbon dioxide or nitrogen through the apparatus at the rate of 2 bubbles per second, place the boiling flask in an oil bath or heating mantle heated to 150°, and continue the reaction for 40 minutes for methoxy determination, or 80 minutes for ethoxy determination. Drain the contents of the absorption tube into a 500-mL conical flask containing 10 mL of sodium acetate solution (1 in 4). Rinse the tube with water, adding the rinsings to the flask, and finally dilute with water to about 125 mL. Add formic acid, dropwise, with swirling, until the reddish brown color of the bromine is discharged, then add 3 additional drops. A total of 12 to 15 drops usually is required. Allow to stand for 3 minutes, and add 15 mL of diluted sulfuric acid and 3 g of potassium iodide, and titrate immediately with 0.1 N sodium thiosulfate VS, using 3 mL of starch TS as the indicator. Perform a blank determination, including also a gelatin capsule, and make any necessary correction. Each mL of 0.1 N sodium thiosulfate is equivalent to 0.517 mg of (OCH<sub>3</sub>).

## Chemical Method

note—Determine from the labeling if the vitamin in the assay specimen is niacin or niacinamide, and use the corresponding standard preparation (either Standard Niacin Preparation or Standard Niacinamide Preparation) as directed in the Procedure.

Cyanogen Bromide Solution— Dissolve 5 g of cyanogen bromide in water to make 50 mL. [Caution—Prepare this solution under a hood, as cyanogen bromide volatilizes at room temperature, and the vapor is highly irritating and poisonous.]

Sulfanilic Acid Solution— To 2.5 g of sulfanilic acid add 15 mL of water and 3 mL of 6 N ammonium hydroxide. Mix, add, with stirring, more 6 N ammonium hydroxide, if necessary, until the acid dissolves, adjust the solution with 3 N hydrochloric acid to a pH of about 4.5, using [bromocresol green RS](#) as an external indicator, and dilute with water to 25 mL.

Standard Niacin Stock Solution— Transfer 25.0 mg of [USP Niacin RS](#) to a 500-mL volumetric flask, dissolve in alcohol solution (1 in 4), dilute with alcohol solution (1 in 4) to volume, and mix. Store in a refrigerator. Each mL of this solution contains 50 µg of [USP Niacin RS](#).

Standard Niacin Preparation— Transfer 10.0 mL of Standard Niacin Stock Solution to a 100-mL volumetric flask, dilute with water to volume, and mix. Each mL of this solution contains 5 µg of [USP Niacin RS](#).

Standard Niacinamide Stock Solution— Transfer 50.0 mg of [USP Niacinamide RS](#) to a 500-mL volumetric flask, dissolve in alcohol solution (1 in 4), dilute with alcohol solution (1 in 4) to volume, and mix. Store in a refrigerator. Each mL of this solution contains 100 µg of [USP Niacinamide RS](#).

Standard Niacinamide Preparation— Transfer 10.0 mL of Standard Niacinamide Stock Solution to a 100-mL volumetric flask, dilute with water to volume, and mix. Each mL of this solution contains 10 µg of [USP Niacinamide RS](#).

## Assay Preparation— Prepare as directed in the individual monograph.

Procedure— Pipet into four marked tubes the quantities of the appropriate Standard Preparation, the Assay Preparation, the ammonia dilution, and water indicated in the accompanying table. Then add the other constituents, respectively, as listed in the table, according to the directions given herein.

## Reaction Mixtures for Niacin or Niacinamide Assay—Chemical Method

Constituent	Tube 1, mL	Tube 2, mL	Tube 3, mL	Tube 4, mL
Standard Preparation	1.0	1.0	—	—
Assay Preparation	—	—	1.0	1.0
Ammonia Dilution (ammonium hydroxide, diluted to 1 in 50)	0.5	0.5	0.5	0.5
Water	6.5	1.5	6.5	1.5
Cyanogen Bromide Solution	—	5.0	—	5.0
Sulfanilic Acid Solution	2.0	2.0	2.0	2.0
Hydrochloric Acid	1 drop	—	1 drop	—

To Tube 1 add the Sulfanilic Acid Solution, shake well, add the hydrochloric acid, mix, place in a suitable spectrophotometer, and adjust to zero absorbance at 450 nm. To Tube 2 add the Cyanogen Bromide Solution, mix, and 30 seconds, accurately timed, after completion of the addition of the cyanogen bromide, add the Sulfanilic Acid Solution, with swirling. Close the tube, place it in the spectrophotometer, and after 2 minutes measure its absorbance at 450 nm against Tube 1 as a blank, designating the absorbance as AS. Repeat the procedure with Tubes 3 (as blank) and 4, designating the absorbance of Tube 4 as AU. Calculate the quantity of niacin or niacinamide in the sample as directed in the individual monograph.

## Microbiological Method

Test Solution of Material to be Assayed— Place the prescribed amount of the material to be assayed in a flask of suitable size, and proceed by one of the methods given below. The concentrations of the sulfuric acid and sodium hydroxide solutions used are not stated in each instance because these concentrations may be varied depending upon the amount of material taken for assay, volume of test solution, and buffering effect of material.

(a) For Dry or Semidry Materials that Contain No Appreciable Amount of Basic Substances—Add a volume of dilute sulfuric acid (1 in 35) equal, in mL, to not less than 10 times the dry weight of the material, in g, but the resulting solution shall contain not more than 5.0 mg of niacin in each mL. If the material is not readily soluble, comminute it so that it may be evenly dispersed in the liquid, then agitate vigorously, and wash down the sides of the flask with dilute sulfuric acid (1 in 35).

Heat the mixture in an autoclave at 121° to 123° for 30 minutes, and cool. If lumping occurs, agitate the mixture until the particles are evenly dispersed. Adjust the mixture with sodium hydroxide solution to a pH of 6.8, dilute with water to make a final measured volume that has a concentration of niacin equivalent to that of Standard Niacin Solution, and filter.

(b) For Dry or Semidry Materials that Contain Appreciable Amounts of Basic Substances—Add sufficient sulfuric acid solution to bring the pH of the mixture to between 5.0 and 6.0. Add such an amount of water that the total volume of liquid shall be equal in mL to not less than ten times the dry weight of the assay specimen, in g, but the resulting solution shall contain not more than 5.0 mg of niacin in each mL. Then add the equivalent of 10 mL of dilute sulfuric acid (2 in 7) for each 100 mL of liquid, and proceed as directed under (a), beginning with the second paragraph.

(c) For Liquid Materials—Adjust the material with either sulfuric acid solution or sodium hydroxide solution to a pH of 5.0 to 6.0. Add such an amount of water that the total volume of liquid shall be equal, in mL, to not less than 10 times the volume of the specimen, in mL, but the resulting solution shall contain not more than 5.0 mg of niacin in each mL. Then add the equivalent of 10 mL of dilute sulfuric acid (2 in 7) for each mL of liquid, and proceed as directed under (a), beginning with the second paragraph.

Standard Niacin Stock Solution I— Transfer 50.0 mg of [USP Niacin RS](#) to a 500-mL volumetric flask, dissolve in alcohol, dilute with alcohol to volume, and mix. Store in a refrigerator. Each mL of this solution contains 100 µg of [USP Niacin RS](#).

Standard Niacin Stock Solution II— To 100.0 mL of Standard Niacin Stock Solution I add water to make 1000.0 mL. Store under toluene in a refrigerator. Each mL of this solution contains 10 µg of [USP Niacin RS](#).

Standard Niacin Solution— Dilute a suitable volume of Standard Niacin Stock Solution II with water to such a measured volume so that after incubation as described in the Assay Procedure the transmittance of the 5.0-mL level of Standard Niacin Solution is equivalent to that of a dried cell weight of not less than 1.25 mg, when the inoculated blank is set at 100 percent transmittance. This concentration is usually between 10 ng and 40 ng of niacin per mL. Prepare a fresh Standard Niacin Solution for each assay.

## Basal Medium Stock Solution—

Acid-hydrolyzed Casein Solution	25 mL
Cystine-Tryptophan Solution	25 mL
Dextrose Anhydrous	10 g
Sodium Acetate Anhydrous	5 g
Adenine-Guanine-Uracil Solution	5 mL
Riboflavin-Thiamine Hydrochloride-Biotin Solution	5 mL
Aminobenzoic Acid-Calcium Pantothenate-Pyridoxine Hydrochloride Solution	5 mL

Salt Solution A	5 mL
Salt Solution B	5 mL

Dissolve the anhydrous dextrose and sodium acetate in the solutions previously mixed, and adjust with 1 N sodium hydroxide to a pH of 6.8. Finally, add water to make 250 mL.

Acid-Hydrolyzed Casein Solution— Mix 100 g of vitamin-free casein with 500 mL of constant-boiling hydrochloric acid [approximately 20 percent (w/w) HCl], and reflux the mixture for 24 hours. Remove the hydrochloric acid from the mixture by distillation under reduced pressure until a thick paste remains. Redisolve the resulting paste in water, adjust the solution with 1 N sodium hydroxide to a pH of 3.5 ( $\pm 0.1$ ), and add water to make 1000 mL. Add 20 g of activated charcoal, stir for 1 hour, and filter. Repeat the treatment with activated charcoal if the filtrate does not appear straw-colored to colorless. Store under toluene in a refrigerator. Filter the solution if a precipitate forms upon storage.

Cystine-Tryptophan Solution— Suspend 4.0 g of L-cystine and 1.0 g of L-tryptophan (or 2.0 g of dl-tryptophan) in 700 to 800 mL of water, heat to 70° to 80°, and add the 20 percent (w/w) hydrochloric acid, dropwise, with stirring, until the solids are dissolved. Cool, and add water to make 1000 mL. Store under toluene in a refrigerator at a temperature not below 10°.

Adenine-Guanine-Uracil Solution— Dissolve 100 mg each of adenine sulfate, guanine hydrochloride, and uracil, with the aid of heat, in 5.0 mL of the 20 percent (w/w) hydrochloric acid, cool, and add water to make 100 mL. Store under toluene in a refrigerator.

Riboflavin-Thiamine Hydrochloride-Biotin Solution— Prepare a solution containing, in each mL, 20  $\mu$ g of riboflavin, 10  $\mu$ g of thiamine hydrochloride, and 0.04  $\mu$ g of biotin by dissolving crystalline riboflavin, crystalline thiamine hydrochloride, and crystalline biotin (free acid) in dilute glacial acetic acid (1 in 850). Store, protected from light, under toluene in a refrigerator.

Aminobenzoic Acid-Calcium Pantothenate-Pyridoxine Hydrochloride Solution— Prepare a solution of neutral 25 percent alcohol having a concentration of 10  $\mu$ g of aminobenzoic acid, 20  $\mu$ g of calcium pantothenate, and 40  $\mu$ g of pyridoxine hydrochloride per mL. Store in a refrigerator.

Salt Solution A— Dissolve 25 g of monobasic potassium phosphate and 25 g of dibasic potassium phosphate in water to make 500 mL. Add 5 drops of hydrochloric acid, and store under toluene.

Salt Solution B— Dissolve 10 g of magnesium sulfate, 500 mg of sodium chloride, 500 mg of ferrous sulfate, and 500 mg of manganese sulfate in water to make 500 mL. Add 5 drops of hydrochloric acid, and store under toluene.

Stock Culture of Lactobacillus plantarum— Dissolve 2.0 g of water-soluble yeast extract in 100 mL of water, add 500 mg of anhydrous dextrose, 500 mg of anhydrous sodium acetate, and 1.5 g of agar, and heat the mixture with stirring, on a steam bath, until the agar dissolves. Add approximately 10-mL portions of the hot solution to test tubes, plug the tubes with cotton, sterilize for 15 minutes in an autoclave at 121° to 123°, and allow the tubes to cool in an upright position. Prepare stab cultures in three or more of the tubes, using a pure culture of Lactobacillus plantarum,\* incubating for 16 to 24 hours at any selected temperature between 30° and 37°, but held constant to within  $\pm 0.5$ °, and finally store in a refrigerator. Prepare a fresh stab of the stock culture every week, and do not use for inoculum if the culture is more than 1 week old.

Culture Medium— To each of a series of test tubes containing 5.0 mL of the Basal Medium Stock Solution add 5.0 mL of water containing 1.0  $\mu$ g of niacin. Plug the tubes with cotton, sterilize for 15 minutes in an autoclave at 121° to 123°, and cool.

Inoculum— Make a transfer of cells from the stock culture of Lactobacillus plantarum to a sterile tube containing 10 mL of culture medium. Incubate this culture for 16 to 24 hours at any selected temperature between 30° and 37°, but held constant to within  $\pm 0.5$ °. The cell suspension so obtained is the inoculum.

Calibration of Spectrophotometer— Add aseptically 1 mL of Inoculum to approximately 300 mL of Culture Medium containing 1 mL of Standard Niacin Solution. Incubate the inoculated medium for the same period and at the same temperature to be employed in the Assay Procedure.

Following the incubation period, centrifuge and wash the cells three times with approximately 50-mL portions of [saline TS](#), and then resuspend the cells in about 25 mL of the saline solution.

Dry to constant weight a 10-mL portion, accurately measured, using a steam bath and completing the drying in vacuum at 100°, and calculate the dry weight of the cells, in mg per mL, corrected for the amount of sodium chloride present.

Dilute a second portion, accurately measured, of the saline cell suspension with the saline solution so that each mL contains a known quantity of cells equivalent to 500  $\mu$ g on a dried basis. To test tubes add, in triplicate, 0.5 mL, 1.0 mL, 1.5 mL, 2.0 mL, 2.5 mL, 3.0 mL, 4.0 mL, and 5.0 mL, respectively, of this diluted cell suspension and 5.0 mL of Basal Medium

Stock Solution, and make the volume in each tube to 10.0 mL with saline solution. Using as the blanks three similar tubes containing no cell suspension, measure the light transmittance of each tube under the same conditions to be employed in the assay. Plot the observations as the ordinate on cross-section paper against the cell content, expressed as mg of dry weight, as the abscissa.

Repeat this procedure at least twice for the spectrophotometer to be used in the assay. Draw the composite curve best representing the three or more individual curves relating transmittance to cell density for the spectrophotometer under the conditions of the assay.

Assay Procedure— Prepare standard niacin tubes as follows. To test tubes add, in duplicate, 0.0 mL, 0.5 mL, 1.0 mL, 1.5 mL, 2.0 mL, 2.5 mL, 3.0 mL, 3.5 mL, 4.0 mL, 4.5 mL, and 5.0 mL, respectively, of Standard Niacin Solution. To each tube add 5.0 mL of Basal Medium Stock Solution and water to make 10.0 mL.

Prepare tubes containing the material to be assayed as follows. To test tubes add, in duplicate, 1.0 mL, 2.0 mL, 3.0 mL, and 4.0 mL, respectively, of the test solution of the material to be assayed. To each tube add 5.0 mL of Basal Medium Stock Solution and water to make 10.0 mL. After mixing, plug the tubes with cotton or cover with caps, and sterilize in an autoclave at 121° to 123°. (Overheating the assay tubes may produce unsatisfactory results.) Cool, aseptically inoculate each tube with 1 drop of Inoculum, and incubate for 16 to 24 hours at any selected temperature between 30° and 37°, but held constant to within  $\pm 0.5$ °. Contamination of the assay tubes with any foreign organism invalidates the assay.

Determine the transmittance of the tubes in the following manner. Mix the contents of each tube, to which 1 drop of a suitable antifoam agent solution may be added, and transfer to an optical container. After agitating its contents, place the container in a spectrophotometer that has been set at a specific wavelength between 540 nm and 660 nm, and read the transmittance when a steady state is reached. This steady state is observed a few seconds after agitation when the reading remains constant for 30 seconds or more. Allow approximately the same time interval for the reading on each tube.

With the transmittance set at 1.00 for the uninoculated blank, read the transmittance of the inoculated blank. If this transmittance reading corresponds to a dried cell weight greater than 600  $\mu$ g per tube, or if there is evidence of contamination with a foreign microorganism, disregard the results of the assay.

Then with the transmittance set at 1.00 for the inoculated blank, read the transmittance for each of the remaining tubes. Disregard the results of the assay if the difference between the transmittance observed at the highest level of the standard and that of the inoculated blank is less than the difference corresponding to a dried cell weight of 1.25 mg per tube.

Calculation— Prepare a standard curve of the niacin standard transmittances for each level of Standard Niacin Solution plotted against  $\mu$ g of niacin contained in the respective tubes. From this standard curve, determine by interpolation the niacin content of the test solution in each tube. Disregard transmittance values equivalent to less than 0.5 mL or more than 4.5 mL of Standard Niacin Solution. The niacin content of the test material is calculated from the average values obtained from not less than six tubes that do not vary by more than  $\pm 10$  percent from the average. If the transmittance values of less than six tubes containing the test solution are within the range of the 0.5- to 4.5-mL levels of the niacin standard tubes, the data are insufficient to permit calculation of the concentration of niacin in the test material. Transmittance values of inoculated blank exceeding readings corresponding to dried cell weights of more than 600  $\mu$ g per tube indicate the presence of an excessive amount of niacin in the Basal Medium Stock Solution and invalidate the assay.

Multiply the values obtained by 0.992 if the results are to be expressed as niacinamide.

\* Pure cultures of Lactobacillus plantarum may be obtained, as number 8014, from the American Type Culture Collection, P.O. Box 1549, Manassas, VA 20108.

**451 NITRITE TITRATION**

The following general method is provided for the determination of most of the Pharmacopeial sulfonamide drugs and their dosage forms, as well as of other Pharmacopeial drugs for which nitrite titration is particularly suitable.

[USP Reference Standards](#) [11](#)—[USP Sulfanilamide RS](#).

**Procedure**— Accurately weigh about 500 mg in the case of a sulfonamide, or otherwise the quantity specified in the individual monograph, and transfer to a suitable open vessel. Add 20 mL of hydrochloric acid and 50 mL of water, stir until dissolved, cool to about 15°, and slowly titrate with 0.1 M sodium nitrite VS that previously has been standardized against [USP Sulfanilamide RS](#).

Determine the endpoint electrometrically, using suitable electrodes (platinum-calomel or platinum-platinum). Place the buret tip below the surface of the solution to eliminate air oxidation of the sodium nitrite, and stir the solution gently, using a magnetic stirrer, without pulling a vortex of air under the surface, maintaining the temperature at about 15°. The titration may be carried out manually, or by means of an automatic titrator. In performing it manually, add the titrant until the titration is within 1 mL of the endpoint, and then add it in 0.1-mL portions, allowing not less than 1 minute between additions. (The instrument needle deflects and then returns to approximately its original position until the endpoint is reached.)

The weight, in mg, of the substance to which each mL of 0.1 M sodium nitrite VS is equivalent is as stated in the individual monograph.

For the assay of Tablets of the sulfonamides or other drugs, reduce not less than 20 tablets to a fine powder, weigh accurately a portion of the powder, equivalent to about 500 mg if a sulfonamide, or the quantity of drug specified in the individual monograph, and proceed as directed in the foregoing, beginning with "transfer to a suitable open vessel."

For the assay of Injections and other liquid forms where the nitrite titration is specified, pipet a portion, equivalent to about 500 mg if a sulfonamide, or the quantity of drug specified in the individual monograph, into a suitable open vessel, and proceed as directed in the foregoing, beginning with "Add 20 mL of hydrochloric acid."

Auxiliary Information— Please [check for your question in the FAQs](#) before contacting USP.

USP32-NF27 Page 161

**461 NITROGEN DETERMINATION**

Some alkaloids and other nitrogen-containing organic compounds fail to yield all of their nitrogen upon digestion with sulfuric acid; therefore these methods cannot be used for the determination of nitrogen in all organic compounds.

**METHOD I**

**Nitrates and Nitrites Absent**— Place about 1 g of the substance, accurately weighed, in a 500-mL Kjeldahl flask of hard borosilicate glass. The material to be tested, if solid or semisolid, may be wrapped in a sheet of nitrogen-free filter paper for convenience in transferring it to the flask. Add 10 g of powdered potassium sulfate or anhydrous sodium sulfate, 500 mg of powdered cupric sulfate, and 20 mL of sulfuric acid. Incline the flask at an angle of about 45°, and gently heat the mixture, keeping the temperature below the boiling point until frothing has ceased. Increase the heat until the acid boils briskly, and continue the heating until the solution has been clear green in color or almost colorless for 30 minutes. Allow to cool, add 150 mL of water, mix the contents of the flask, and again cool. Add cautiously 100 mL of sodium hydroxide solution (2 in 5), in such manner as to cause the solution to flow down the inner side of the flask to form a layer under the acid solution. Immediately add a few pieces of granulated zinc, and without delay connect the flask to a Kjeldahl connecting bulb (trap), previously attached to a condenser, the delivery tube from which dips beneath the surface of 100 mL of boric acid solution (1 in 25) contained in a conical flask or a wide-mouth bottle of about 500-mL capacity. Mix the contents of the Kjeldahl flask by gentle rotation, and distill until about four-fifths of the contents of the flask has distilled over. Titrate with 0.5 N sulfuric acid VS, determining the endpoint potentiometrically. Perform a blank determination, and make any necessary correction. Each mL of 0.5 N sulfuric acid VS is equivalent to 7.003 mg of nitrogen.

When the nitrogen content of the substance is known to be low, the 0.5 N sulfuric acid VS may be replaced by 0.1 N sulfuric acid VS. Each mL of 0.1 N sulfuric acid VS is equivalent to 1.401 mg of nitrogen.

**Nitrates and Nitrites Present**— Place a quantity of the substance, accurately weighed, corresponding to about 150 mg of nitrogen, in a 500-mL Kjeldahl flask of hard borosilicate glass, and add 25 mL of sulfuric acid in which 1 g of salicylic acid previously has been dissolved. Mix the contents of the flask, and allow the mixture to stand for 30 minutes with frequent shaking. To the mixture add 5 g of powdered sodium thiosulfate, again mix, then add 500 mg of powdered cupric sulfate, and proceed as directed under Nitrates and Nitrites Absent, beginning with "Incline the flask at an angle of about 45°."

When the nitrogen content of the substance is known to exceed 10%, 500 mg to 1 g of benzoic acid may be added, prior to digestion, to facilitate the decomposition of the substance.

**METHOD II**

**Apparatus**— Select an appropriate 300-mL Kjeldahl flask, from which the nitrogen is first liberated by acid digestion and then transferred quantitatively to the titration vessel by steam distillation.

**Procedure**— Place an accurately weighed or measured quantity of the material, equivalent to 2 to 3 mg of nitrogen, in the digestion flask of the apparatus. Add 1 g of a powdered mixture of potassium sulfate and cupric sulfate (10:1), and wash down any adhering material from the neck of the flask with a fine jet of water. Add 7 mL of sulfuric acid, allowing it to rinse down the wall of the flask, then, while swirling the flask, add 1 mL of 30 percent hydrogen peroxide cautiously down the side of the flask. (Do not add hydrogen peroxide during the digestion.)

Heat the flask over a free flame or an electric heater until the solution has a clear blue color and the sides of the flask are free from carbonaceous material. Cautiously add to the

gation mixture 70 mL of water, cool the solution, and arrange for steam distillation. Add through a funnel 30 mL of sodium hydroxide solution (2 in 5) in such manner as to cause the solution to flow down the inner side of the flask to form a layer under the acid solution, rinse the funnel with 10 mL of water, tightly close the apparatus, and begin the distillation with steam immediately. Receive the distillate in 15 mL of boric acid solution (1 in 25), to which has been added 3 drops of methyl red-methylene blue TS and sufficient water to cover the end of the condensing tube. Continue the distillation until the distillate measures 80 to 100 mL. Remove the absorption flask, rinse the end of the condensing tube with a small quantity of water, and titrate the distillate with 0.01 N sulfuric acid VS. Perform a blank determination, and make any necessary correction. Each mL of 0.01 N sulfuric acid VS is equivalent to 140.1  $\mu$ g of nitrogen.

When a quantity of material containing more than 2 to 3 mg of nitrogen is taken, 0.02 N or 0.1 N sulfuric acid may be employed, provided that at least 15 mL is required for the titration. If the total dry weight of material taken is greater than 100 mg, increase proportionately the quantities of sulfuric acid and sodium hydroxide.

Auxiliary Information— Please [check for your question in the FAQs](#) before contacting USP.

## 466 ORDINARY IMPURITIES

This test, where called for in the individual monograph, is provided to evaluate the presence of ordinary impurities in official articles. Ordinary impurities are defined as those species in drug substances and/or drug products that have no significant, undesirable biological activity in the amounts present. These impurities may arise out of the synthesis, preparation, or degradation of compendial articles. In certain instances, impurities that pose a potential health risk may be detected. Because these impurities would not be individually identified by the strict use of this General Chapter, a separate evaluation may be necessary to ensure that the detected impurities fit the requirements set forth in the definition of Ordinary Impurities. Selections of tests and assays allow for anticipated amounts of impurities that are unobjectionable for the customary use of the article.

**Reporting and Specifications**— The value of 2.0%, unless otherwise specified in the individual monograph, was selected as the general limit for the total amount of ordinary impurities in monographs where documentation did not support adoption of other values.

Where a monograph sets limits on concomitant components and/or specified impurities/degradation products, these species are not to be included in the estimation of ordinary impurities unless so stated in the individual monograph. Concomitant components are defined as species characteristic of many drug substances that are not considered to be impurities in the Pharmacopeial sense. Examples of concomitant components are geometric and optical isomers (or racemates) and antibiotics that are mixtures. Any component that can be considered a toxic impurity because of significant undesirable biological effect is not considered to be a concomitant component.

**Methodology**— Unless otherwise specified in an individual monograph, estimation of the amount and number of ordinary impurities is made by relative methods rather than by strict comparison to individual Reference Standards. Nonspecific detection of ordinary impurities is also consistent with this classification.

Typical evaluation methods used for ordinary impurities are thin-layer chromatographic (TLC) techniques. See [Chromatography](#) (621) for a general discussion of the thin-layer chromatographic technique. Tests for related substances or chromatographic purity may also be used to evaluate the presence of ordinary impurities. Other methods (e.g., HPLC, HPTLC, etc.) may also be used with adequate justification as an alternate method. Unless otherwise specified in the individual monograph, use the following method.

**Test Solution**— Prepare, in the solvent specified in the monograph, a solution of the substance under test having an accurately known final concentration of about 10 mg per mL. [note—Heat or sonication may be used to dissolve the drug substance where use of such does not adversely affect the compound.]

**Standard Solutions**— Prepare, in the solvent specified in the monograph, solutions of the USP Reference Standard or designated substance having accurately known concentrations of 0.01 mg per mL, 0.05 mg per mL, 0.1 mg per mL, and 0.2 mg per mL. [note—Heat or sonication may be used to dissolve the drug substance where use of such does not adversely affect the compound.]

**Procedure**— Use a thin-layer chromatographic plate coated with a 0.25-mm layer of chromatographic silica gel mixture, and the Eluant specified in the monograph. Apply equal volumes (20  $\mu$ L) of the Test Solution and Standard Solutions to the plate, using a stream of nitrogen to dry the spots.

Allow the chromatogram to develop in a pre-equilibrated chamber until the solvent front has moved about three-fourths of the length of the plate. Remove the plate from the chamber, and air-dry. View the plate using the visualization technique(s) specified. Locate any spots other than the principal spot in the chromatogram of the Test Solution, and determine their relative intensities by comparison with the chromatograms of the appropriate Standard Solutions. See discussion above with regard to reporting and specifying total ordinary impurities.

### key for visualization techniques

(1) Use UV light at 254 nm and at about 366 nm.

(2) Use Iodoplatinate TS.

(3) Solution A—Mix 850 mg of bismuth subnitrate with 40 mL of water and 10 mL of glacial acetic acid.

**Solution B**—Dissolve 8 g of potassium iodide in 20 mL of water. Mix A and B together to obtain a Stock Solution which can be stored for several months in a dark bottle. Mix 10 mL of the Stock Solution with 20 mL of glacial acetic acid, and dilute with water to make 100 mL, to prepare the spray reagent.

(4) Ninhydrin Spray—Dissolve 200 mg of ninhydrin in 100 mL of alcohol. Heat the plate after spraying.

(5) Acid Spray—In an ice bath, add slowly and cautiously, with stirring, 10 mL of sulfuric acid to 90 mL of alcohol. Spray the plate, and heat until charred.

(6) Acid-Dichromate Spray—Add sufficient potassium dichromate to 100 mL of sulfuric acid to make a saturated solution. Spray the plate, and heat until charred.

(7) Vanillin—Dissolve 1 g of vanillin in 100 mL of sulfuric acid.

(8) Chloramine T-Trichloroacetic Acid—Mix 10 mL of a 3% aqueous solution of chloramine T with 40 mL of a 25% alcoholic solution of trichloroacetic acid. Prepare immediately before use.

(9) Folin-C—Add 10 g of sodium tungstate and 2.5 g of sodium molybdate to 70 mL of water, add 5 mL of 85% phosphoric acid and 10 mL of 36% hydrochloric acid, and reflux this solution for 10 hours.

(10) KMnO<sub>4</sub>—Dissolve 100 mg of Potassium Permanganate in 100 mL of water.

(11) DAB—Mix 1 g of p-dimethylaminobenzaldehyde in 100 mL of 0.6 N hydrochloric acid.

(12) DAC—Mix 100 mg of p-dimethylaminocinnamaldehyde in 100 mL of 1 N hydrochloric acid.

(13) Ferricyanide—Mix equal volumes of a 1% ferric chloride solution and a 1% potassium ferricyanide solution. Use immediately.

(14) Fast Blue B—Reagent A—Dissolve 500 mg of Fast Blue B Salt in 100 mL of water.

Reagent B—0.1 N sodium hydroxide.

Spray first with A, then with B.

(15) Alkaline Ferric Cyanide—Dilute 1.5 mL of a 1% potassium ferricyanide solution with water to 20 mL, and add 10 mL of 15% sodium hydroxide solution.

(16) Iodine Spray—Prepare a 0.5% solution of iodine in chloroform.

(17) Expose the plate for 10 minutes to iodine vapors in a pre-equilibrated closed chamber, on the bottom of which there are iodine crystals.

(18) Solution A—Dissolve 0.5 g of potassium iodide in 50 mL of water.

Solution B—Prepare a solution of 0.5 g of soluble starch in 50 mL of hot water.

Just prior to use, mix equal volumes of Solution A and Solution B.

(19) PTSS—Dissolve 20 g of p-toluenesulfonic acid in 100 mL of alcohol, spray the plate, dry for 15 minutes at 110°, and view under UV light at 366 nm.

(20) o-Tolidine Spray—Dissolve 160 mg of o-tolidine in 30 mL of glacial acetic acid, dilute with water to make 500 mL, add 1 g of potassium iodide, and mix until the potassium iodide has dissolved.

(21) Mix 3 mL of chloroplatinic acid solution (1 in 10) with 97 mL of water, followed by the addition of 100 mL of potassium iodide solution (6 in 100) to prepare the spray reagent.

(22) Iodine–Methanol Spray—Prepare a mixture of [iodine TS](#) and methanol (1:1).

Auxiliary Information— Please [check for your question in the FAQs](#) before contacting USP.

## 467 RESIDUAL SOLVENTS

### INTRODUCTION

This general chapter applies to existing drug substances, excipients, and products. All substances and products are subject to relevant control of solvents likely to be present in a substance or product.

Where the limits to be applied comply with those given below, tests for residual solvents are not generally mentioned in specific monographs because the solvents employed may vary from one manufacturer to another.

The objective of this general chapter is to provide acceptable amounts of residual solvents in pharmaceuticals for the safety of the patient. The general chapter recommends the use of less toxic solvents and describes levels considered to be toxicologically acceptable for some residual solvents.

For pharmacopeial purposes, residual solvents in pharmaceuticals are defined as organic volatile chemicals that are used or produced in the manufacture of drug substances or excipients, or in the preparation of drug products. The residual solvents are not completely removed by practical manufacturing techniques. Appropriate selection of the solvent for the synthesis of a drug substance or an excipient may enhance the yield, or determine characteristics such as crystal form, purity, and solubility. Therefore, the solvent may sometimes be a critical element in the synthetic process. This general chapter does not address solvents deliberately used as excipients nor does it address solvates. However, the content of solvents in such products should be evaluated and justified.

Because residual solvents do not provide therapeutic benefit, they should be removed, to the extent possible, to meet ingredient and product specifications, good manufacturing practices, or other quality-based requirements. Drug products should contain no higher levels of residual solvents than can be supported by safety data. Solvents that are known to cause unacceptable toxicities (Class 1, [Table 1](#)) should be avoided in the production of drug substances, excipients, or drug products unless their use can be strongly justified in a risk-benefit assessment. Solvents associated with less severe toxicity (Class 2, [Table 2](#)) should be limited in order to protect patients from potential adverse effects. Ideally, less toxic solvents (Class 3, [Table 3](#)) should be used where practical. The complete list of solvents included in this general chapter is given in Appendix 1. These tables and the list are not exhaustive. For the purposes of this Pharmacopeia, when a manufacturer has received approval from a competent regulatory authority for the use of a new solvent not currently listed in this general chapter, it is the responsibility of that manufacturer to notify the USP regarding the identity of this solvent, the approved residual solvent limit in the article, and the appropriate test procedure for this residual solvent in the article. The USP will then address this topic in the individual monograph. When a new solvent has been approved through the ICH process, this new solvent will be added to the appropriate list in this general chapter. At that time consideration will be given for removal of the specific solvent test requirement in the individual monograph.

Testing of drug substances, excipients, and drug products for residual solvents should be performed when production or purification processes are known to result in the presence of such residual solvents. It is only necessary to test for residual solvents that are used or produced in the manufacture or purification of drug substances, excipients, or products.

Although manufacturers may choose to test the drug product, a cumulative procedure may be used to calculate the residual solvent levels in the drug product from the levels in the ingredients used to produce the drug product. If the calculation results in a level equal to or below that provided in this general chapter, no testing of the drug product for residual solvents need be considered. If, however, the calculated level is above the recommended level, the drug product should be tested to ascertain whether the formulation process has reduced the relevant solvent level to within the acceptable amount. A drug product should also be tested if a residual solvent is used during its manufacture.

For the purposes of this Pharmacopeia, when a manufacturer has received approval from a competent regulatory authority for a higher level of residual solvent, it is the responsibility of that manufacturer to notify the USP regarding the identity of this solvent and the approved residual solvent limit in the article. The USP will then address this topic in the individual monograph.

See Appendix 2 for additional background information related to residual solvents.

### CLASSIFICATION OF RESIDUAL SOLVENTS BY RISK ASSESSMENT

The term "tolerable daily intake" (TDI) is used by the International Program on Chemical Safety (IPCS) to describe exposure limits of toxic chemicals and the term "acceptable daily intake" (ADI) is used by the World Health Organization (WHO) and other national and international health authorities and institutes. The term "permitted daily exposure" (PDE) is defined as a pharmaceutically acceptable intake of residual solvents to avoid confusion of differing values for ADIs of the same substance.

Residual solvents assessed in this general chapter are listed in Appendix 1 by common names and structures. They were evaluated for their possible risk to human health and placed into one of three classes as follows:

Residual Solvent Class	Assessment
Class 1	Solvents to be avoided Known human carcinogens Strongly suspected human carcinogens Environmental hazards

Class 2	Solvents to be limited
	Nongenotoxic animal carcinogens or possible causative agents of other irreversible toxicity, such as neurotoxicity or teratogenicity.
	Solvents suspected of other significant but reversible toxicities.
Class 3	Solvents with low toxic potential
	Solvents with low toxic potential to humans; no health-based exposure limit is needed. [note—Class 3 residual solvents have PDEs of 50 mg or more per day.]

\* For residual solvents with PDEs of more than 50 mg per day, see the discussion in the section Class 3 under Limits of Residual Solvents.

#### METHODS FOR ESTABLISHING EXPOSURE LIMITS

The method used to establish permitted daily exposures for residual solvents is presented in Appendix 3.

For articles that are designated "for veterinary use only", higher levels for the PDE and concentration limit may be justified in exceptional cases based upon the actual daily dose, actual target species, and relevant toxicological data and considering consumer safety impact. For the purpose of this Pharmacopeia, when a manufacturer has received approval from a competent regulatory authority for a higher limit, it is the responsibility of that manufacturer to notify the USP regarding the approved residual solvent limit in the article and the justification. The USP will then address this topic in the individual monograph.

#### OPTIONS FOR DESCRIBING LIMITS OF CLASS 2 RESIDUAL SOLVENTS

Two options are available when setting limits for Class 2 residual solvents.

##### Option 1

The concentration limits in ppm stated in [Table 2](#) are used. They were calculated using equation (1) below by assuming a product weight of 10 g administered daily.

$$\text{Concentration (ppm)} = (1000 \mu\text{g}/\text{mg} \times \text{PDE})/\text{dose}$$

Here, PDE is given in terms of mg per day, and dose is given in g per day.

These limits are considered acceptable for all drug substances, excipients, and drug products. Therefore, this option may be applied if the daily dose is not known or fixed. If all drug substances and excipients in a formulation meet the limits given in Option 1, these components may be used in any proportion. No further calculation is necessary provided the daily dose does not exceed 10 g. Products that are administered in doses greater than 10 g per day are to be considered under Option 2.

##### Option 2

It is not necessary for each component of the drug product to comply with the limits given in Option 1. The PDE in terms of mg per day as stated in [Table 2](#) can be used with the known maximum daily dose and equation (1) above to determine the concentration of residual solvent allowed in a drug product. Such limits are considered acceptable provided that it has been demonstrated that the residual solvent has been reduced to the practical minimum. The limits should be realistic in relation to analytical precision, manufacturing capability, and reasonable variation in the manufacturing process. The limits should also reflect contemporary manufacturing standards.

Option 2 may be applied by adding the amounts of a residual solvent present in each of the components of the drug product. The sum of the amounts of solvent per day should be less than that given by the PDE.

Consider an example of the application of Option 1 and Option 2 to acetonitrile concentration in a drug product. The permitted daily exposure to acetonitrile is 4.1 mg per day; thus, the Option 1 limit is 410 ppm. The maximum administered daily weight of a drug product is 5.0 g, and the drug product contains two excipients. The composition of the drug product and the calculated maximum content of residual acetonitrile are given in the following table.

Component	Amount in Formulation (g)	Acetonitrile Content (ppm)	Daily Exposure (mg)
Drug substance	0.3	800	0.24
Excipient 1	0.9	400	0.36
Excipient 2	3.8	800	3.04
Drug product	5.0	728	3.64

Excipient 1 meets the Option 1 limit, but the drug substance, excipient 2, and drug product do not meet the Option 1 limit. Nevertheless, the drug product meets the Option 2 limit of 4.1 mg per day and thus conforms to the acceptance criteria in this General Chapter.

Consider another example using acetonitrile as the residual solvent. The maximum administered daily weight of a drug product is 5.0 g, and the drug product contains two excipients. The composition of the drug product and the calculated maximum content of residual acetonitrile are given in the following table.

Component	Amount in Formulation (g)	Acetonitrile Content (ppm)	Daily Exposure (mg)
Drug substance	0.3	800	0.24
Excipient 1	0.9	2000	1.80
Excipient 2	3.8	800	3.04
Drug product	5.0	1016	5.08

In this example, the drug product meets neither the Option 1 nor the Option 2 limit according to this summation. The manufacturer could test the drug product to determine if the formulation process reduced the level of acetonitrile. If the level of acetonitrile was not reduced to the allowed limit during formulation, the product fails to meet the solvent limits as described in this chapter and the manufacturer of the drug product should take other steps to reduce the amount of acetonitrile in the drug product. In some instances the manufacturer may have received approval from a competent regulatory authority for such a higher level of residual solvent. If this is the case, it is the responsibility of that manufacturer to notify the USP regarding the identity of this solvent and the approved residual solvent limit in the article. The USP will then address this topic in the individual monograph.

#### ANALYTICAL PROCEDURES

Residual solvents are typically determined using chromatographic techniques such as gas chromatography. Compendial methods for testing for residual solvent content are described under the Identification, Control, and Quantification of Residual Solvents section of this general chapter. The General Notices discuss the use of other methods in special circumstances (see Procedures in Tests and Assays). If Class 3 solvents are present, a nonspecific method such as loss on drying may be used.

#### REPORTING LEVELS OF RESIDUAL SOLVENTS

Manufacturers of pharmaceutical products need certain information about the content of residual solvents in drug substances or excipients in order to meet the criteria of this general chapter. The following statements are given as acceptable examples of the information that could be provided from a supplier of drug substances or excipients to a pharmaceutical manufacturer. The supplier might choose one of the following as appropriate:

- Only Class 3 solvents are likely to be present. Loss on drying is less than 0.5%.
- Only Class 2 solvents X, Y, ... are likely to be present. All are below the Option 1 limit. (Here the supplier would name the Class 2 solvents represented by X, Y, ...)
- Only Class 2 solvents X, Y, ... and Class 3 solvents are likely to be present. Residual Class 2 solvents are below the Option 1 limit and residual Class 3 solvents are below 0.5%.

The phrase "likely to be present" as used in the above examples refers to the solvent used or produced in the final manufacturing step and to solvents that are used or produced in earlier manufacturing steps and not removed consistently by a validated process.

If Class 1 solvents are likely to be present, they should be identified and quantified. If solvents of Class 2 or 3 are present at greater than their Option 1 limits or 0.5%, respectively, they should be identified and quantified.

#### LIMITS OF RESIDUAL SOLVENTS

##### Ethylene Oxide

[note—The test for ethylene oxide is conducted only where specified in the individual monograph.] The standard solution parameters and the procedure for determination are described in the individual monograph. Unless otherwise specified in the individual monograph, the limit is 10 µg per g.

##### Class 1 (solvents to be avoided)

Class 1 residual solvents ([Table 1](#)) should not be employed in the manufacture of drug substances, excipients, and drug products because of the unacceptable toxicities or deleterious environmental effects of these residual solvents. However, if their use in order to produce a medicinal product with a significant therapeutic advance is unavoidable, their levels should be restricted as shown in [Table 1](#), unless otherwise stated in the individual monograph. The solvent 1,1,1-trichloroethane is included in [Table 1](#) because it is an environmental hazard.

The stated limit of 1500 ppm is based on a review of safety data.

When Class 1 residual solvents are used or produced in the manufacture or purification of a drug substance, excipient, or drug product and are not removed by the process, these solvents should be identified and quantified. The procedures described in the Identification, Control, and Quantification of Residual Solvents section of this general chapter are to be applied wherever possible. Otherwise an appropriate validated procedure is to be employed.

Table 1. Class 1 Residual Solvents  
(solvents that should be avoided)

Solvent	Concentration Limit (ppm)	Concern
Benzene	2	Carcinogen
Carbon tetrachloride	4	Toxic and environmental hazard
1,2-Dichloroethane	5	Toxic
1,1-Dichloroethene	8	Toxic
1,1,1-Trichloroethane	1500	Environmental hazard

##### Class 2

Class 2 residual solvents ([Table 2](#)) should be limited in drug substances, excipients, and drug products because of the inherent toxicities of the residual solvents. PDEs are given to the nearest 0.1 mg per day, and concentrations are given to the nearest 10 ppm. The stated values do not reflect the necessary analytical precision of the determination procedure. Precision should be determined as part of the procedure validation.

If Class 2 residual solvents are present at greater than their Option 1 limits, they should be identified and quantified. The procedures described in the Identification, Control, and Quantification of Residual Solvents section of this general chapter are to be applied wherever possible. Otherwise an appropriate validated procedure is to be employed.

[note—The following Class 2 residual solvents are not readily detected by the headspace injection conditions described in the Identification, Control, and Quantification of Residual Solvents section of this general chapter: formamide, 2-ethoxyethanol, 2-methoxyethanol, ethylene glycol, N-methylpyrrolidone, and sulfolane. Other appropriate validated procedures are to be employed for the quantification of these residual solvents. Such procedures shall be submitted to the USP for review and possible inclusion in the relevant individual monograph. In addition, USP Residual Solvent Class 2—Mixture C RS can be used to develop an alternative procedure.]

Table 2. Class 2 Residual Solvents

Solvent	PDE (mg/day)	Concentration Limit (ppm)
Acetonitrile	4.1	410
Chlorobenzene	3.6	360
Chloroform	0.6	60
Cyclohexane	38.8	3880
1,2-Dichloroethene	18.7	1870
1,2-Dimethoxyethane	1.0	100
N,N-Dimethylacetamide	10.9	1090
N,N-Dimethylformamide	8.8	880
1,4-Dioxane	3.8	380
2-Ethoxyethanol	1.6	160
Ethylene glycol	6.2	620
Formamide	2.2	220
Hexane	2.9	290
Methanol	30.0	3000
2-Methoxyethanol	0.5	50
Methylbutylketone	0.5	50
Methylcyclohexane	11.8	1180
Methylene chloride	6.0	600

N-Methylpyrrolidone	5.3	530
Nitromethane	0.5	50
Pyridine	2.0	200
Sulfolane	1.6	160
Tetrahydrofuran	7.2	720
Tetralin	1.0	100
Toluene	8.9	890
Trichloroethylene	0.8	80
Xylene <sup>*</sup>	21.7	2170

\* Usually 60% m-xylene, 14% p-xylene, 9% o-xylene with 17% ethyl benzene

### Class 3

Class 3 residual solvents (Table 3) may be regarded as less toxic and of lower risk to human health than Class 1 and Class 2 residual solvents. Class 3 includes no solvent known as a human health hazard at levels normally accepted in pharmaceuticals. However, there are no long-term toxicity or carcinogenicity studies for many of the residual solvents in Class 3.

Available data indicate that they are less toxic in acute or short-term studies and negative in genotoxicity studies.

It is considered that amounts of these residual solvents of 50 mg per day or less (corresponding to 5000 ppm or 0.5% under Option 1) would be acceptable without justification. Higher amounts may also be acceptable provided they are realistic in relation to manufacturing capability and good manufacturing practice. For the purposes of this Pharmacopeia, when a manufacturer has received approval from a competent regulatory authority for such a higher level of residual solvent, it is the responsibility of that manufacturer to notify the USP regarding the identity of this solvent and the approved residual solvent limit in the article. The USP will then address this topic in the individual monograph. If a Class 3 solvent limit in an individual monograph is greater than 50 mg per day, that residual solvent should be identified and quantified. The procedures described in the Identification, Control, and Quantification of Residual Solvents section of this General Chapter, with appropriate modifications to the standard solutions, are to be applied wherever possible. Otherwise an appropriate validated procedure is to be employed.

Table 3. Class 3 Residual Solvents  
(limited by GMP or other quality-based requirements in drug substances, excipients, and drug products)

Acetic acid	Heptane
Acetone	Isobutyl acetate
Anisole	Isopropyl acetate
1-Butanol	Methyl acetate
2-Butanol	3-Methyl-1-butanol
Butyl acetate	Methylethylketone
tert-Butylmethyl ether	Methylisobutylketone
Cumene	2-Methyl-1-propanol
Dimethyl sulfoxide	Pentane
Ethanol	1-Pentanol
Ethyl acetate	1-Propanol
Ethyl ether	2-Propanol
Ethyl formate	Propyl acetate
Formic acid	

### Other Residual Solvents

The residual solvents listed in Table 4 may also be of interest to manufacturers of drug substances, excipients, or drug products. However, no adequate toxicological data on which to base a PDE was found.

Table 4. Other Residual Solvents  
(for which no adequate toxicological data was found)

1,1-Diethoxypropane	Methyl isopropyl ketone
1,1-Dimethoxymethane	Methyltetrahydrofuran
2,2-Dimethoxypropane	Solvent hexane
Isooctane	Trichloroacetic acid
Isopropyl ether	Trifluoroacetic acid

### IDENTIFICATION, CONTROL, AND QUANTIFICATION OF RESIDUAL SOLVENTS

Whenever possible, the substance under test needs to be dissolved to release the residual solvent. Because the USP deals with drug products, as well as active ingredients and excipients, it may be acceptable that in cases some of the components of the formulation will not dissolve completely. In those cases, the drug product may first need to be pulverized into a fine powder so that any residual solvent that may be present can be released. This operation should be as fast as possible to prevent the loss of volatile solvents during the procedure.

note—The organic-free water specified in the following procedures produces no significantly interfering peaks when chromatographed.

#### Class 1 and Class 2 Residual Solvents

The following procedures are useful to identify and quantify residual solvents when the information regarding which solvents are likely to be present in the material is not available. When the information about the presence of specific residual solvents is available, only Procedure C is needed to quantify the amount of residual solvents present.

##### water-soluble articles

###### Procedure A—

Class 1 Standard Stock Solution—Transfer 1.0 mL of USP Class 1 Residual Solvents Mixture RS to a 100-mL volumetric flask, add 9 mL of dimethyl sulfoxide, dilute with water to volume, and mix. Transfer 1.0 mL of this solution to a 100-mL volumetric flask, dilute with water to volume, and mix. Transfer 1.0 mL of this solution to a 10-mL volumetric flask, dilute with water to volume, and mix.

Class 1 Standard Solution—Transfer 1.0 mL of Class 1 Standard Stock Solution to an appropriate headspace vial, add 5.0 mL of water, apply the stopper, cap, and mix.

Class 2 Standard Stock Solutions—Transfer 1.0 mL of USP Residual Solvents Class 2—Mixture A RS to a 100-mL volumetric flask, dilute with water to volume, and mix. This is Class 2 Standard Stock Solution A. Transfer 1.0 mL of USP Residual Solvents Class 2—Mixture B RS to a 100-mL volumetric flask, dilute with water to volume, and mix. This is Class 2

## Standard Stock Solution B.

Class 2 Mixture A Standard Solution—Transfer 1.0 mL of Class 2 Standard Stock Solution A to an appropriate headspace vial, add 5.0 mL of water, apply the stopper, cap, and mix.

Class 2 Mixture B Standard Solution—Transfer 5.0 mL of Class 2 Standard Stock Solution B to an appropriate headspace vial, add 1.0 mL of water, apply the stopper, cap, and mix.

Test Stock Solution—Transfer about 250 mg of the article under test, accurately weighed, to a 25-mL volumetric flask, dissolve in and dilute with water to volume, and mix.

Test Solution—Transfer 5.0 mL of Test Stock Solution to an appropriate headspace vial, add 1.0 mL of water, apply the stopper, cap, and mix.

Class 1 System Suitability Solution—Transfer 1.0 mL of Class 1 Standard Stock Solution to an appropriate headspace vial, add 5.0 mL of Test Stock Solution, apply the stopper, cap, and mix.

Chromatographic System (see [Chromatography 621](#))—The gas chromatograph is equipped with a flame-ionization detector, a 0.32-mm × 30-m fused-silica column coated with a 1.8-μm layer of phase G43 or a 0.53-mm × 30-m wide-bore column coated with a 3.0-μm layer of phase G43. The carrier gas is nitrogen or helium with a linear velocity of about 35 cm per second, and a split ratio of 1:5. [note—Split ratio can be modified in order to optimize sensitivity.] The column temperature is maintained at 40° for 20 minutes, then raised at a rate of 10° per minute to 240°, and maintained at 240° for 20 minutes. The injection port and detector temperatures are maintained at 140° and 250°, respectively. Chromatograph the Class 1 Standard Solution, Class 1 System Suitability Solution, and Class 2 Mixture A Standard Solution, and record the peak responses as directed for Procedure: the signal-to-noise ratio of 1,1,1-trichloroethane in the Class 1 Standard Solution is not less than 5; the signal-to-noise ratio of each peak in the Class 1 System Suitability Solution is not less than 3; and the resolution, R, between acetonitrile and methylene chloride in the Class 2 Mixture A Standard Solution is not less than 1.0.

Procedure—Separately inject (following one of the headspace operating parameter sets described in the table below) equal volumes of headspace (about 1.0 mL) of the Class 1 Standard Solution, Class 2 Mixture A Standard Solution, Class 2 Mixture B Standard Solution, and the Test Solution into the chromatograph, record the chromatograms, and measure the responses for the major peaks. If a peak response of any peak, other than a peak for 1,1,1-trichloroethane, in the Test Solution is greater than or equal to a corresponding peak in either the Class 1 Standard Solution or either of the two Class 2 Mixture Standard Solutions, or a peak response of 1,1,1-trichloroethane is greater than or equal to 150 times the peak response corresponding to 1,1,1-trichloroethane in the Class 1 Standard Solution, proceed to Procedure B to verify the identity of the peak; otherwise the article meets the requirements of this test.

Table 5. Headspace Operating Parameters

	Headspace Operating Parameter Sets		
	1	2	3
Equilibration temperature (°)	80	105	80
Equilibration time (min.)	60	45	45
Transfer-line temperature (°)	85	110	105
Carrier gas: nitrogen or helium at an appropriate pressure			
Pressurization time (s)	30	30	30
Injection volume (mL)	1	1	1

## Procedure B—

Class 1 Standard Stock Solution, Class 1 Standard Solution, Class 2 Standard Stock Solutions, Class 2 Mixture A Standard Solution, Class 2 Mixture B Standard Solution, Test Stock Solution, Test Solution, and Class 1 System Suitability Solution—Prepare as directed for Procedure A.

Chromatographic System (see [Chromatography 621](#))—The gas chromatograph is equipped with a flame-ionization detector, a 0.32-mm × 30-m fused-silica column coated with a 0.25-μm layer of phase G16, or a 0.53-mm × 30-m wide-bore column coated with a 0.25-μm layer of phase G16. The carrier gas is nitrogen or helium with a linear velocity of about 35 cm per second and a split ratio of 1:5. [note—Split ratio can be modified in order to optimize sensitivity.] The column temperature is maintained at 50° for 20 minutes, then raised at a rate of 6° per minute to 165°, and maintained at 165° for 20 minutes. The injection port and detector temperatures are maintained at 140° and 250°, respectively. Chromatograph the Class 1 Standard Solution and the Class 1 System Suitability Solution, and record the peak responses as directed for Procedure: the signal-to-noise ratio of benzene in the Class 1 Standard Solution is not less than 5; the signal-to-noise ratio of each peak in the Class 1 System Suitability Solution is not less than 3; and the resolution, R, between acetonitrile and cis-dichloroethene in the Class 2 Mixture A Standard Solution is not less than 1.0.

Procedure—Separately inject (following one of the headspace operating parameter sets described in [Table 5](#)) equal volumes of headspace (about 1.0 mL) of the Class 1 Standard Solution, the Class 2 Mixture A Standard Solution, the Class 2 Mixture B Standard Solution, and the Test Solution into the chromatograph, record the chromatograms, and measure the responses for the major peaks. If the peak response(s) in the Test Solution of the peak(s) identified in Procedure A is/are greater than or equal to a corresponding peak(s) in either the Class 1 Standard Solution or either of the two Class 2 Mixture Standard Solutions, proceed to Procedure C to quantify the peak(s); otherwise the article meets the requirements of this test.

## Procedure C—

Class 1 Standard Stock Solution, Class 1 Standard Solution, Class 2 Standard Stock Solution A, Class 2 Mixture A Standard Solution, Test Stock Solution, Test Solution, and Class 1 System Suitability Solution—Prepare as directed for Procedure A.

Standard Solution—[note—Prepare a separate Standard Solution for each peak identified and verified by Procedures A and B. For the Class 1 solvents other than 1,1,1-trichloroethane, prepare the first dilution as directed for the first dilution under Class 1 Standard Stock Solution in Procedure A.] Transfer an accurately measured volume of each individual USP Reference Standard corresponding to each residual solvent peak identified and verified by Procedures A and B to a suitable container, and dilute quantitatively, and stepwise if necessary, with water to obtain a solution having a final concentration of 1/20 of the value stated in [Table 1](#) or [2](#) (under Concentration Limit). Transfer 1.0 mL of this solution to an appropriate headspace vial, add 5.0 mL of water, apply the stopper, cap, and mix.

Spiked Test Solution—[note—Prepare a separate Spiked Test Solution for each peak identified and verified by Procedures A and B.] Transfer 5.0 mL of Test Stock Solution to an appropriate headspace vial, add 1.0 mL of the Standard Solution, apply the stopper, cap, and mix.

Chromatographic System (see [Chromatography 621](#))—[note—If the results of the chromatography from Procedure A are found to be inferior to those found with Procedure B, the Chromatographic System from Procedure B may be substituted.] The gas chromatograph is equipped with a flame-ionization detector, a 0.32-mm × 30-m fused-silica column coated with a 1.8-μm layer of phase G43 or a 0.53-mm × 30-m wide-bore column coated with a 3.0-μm layer of phase G43. The carrier gas is nitrogen or helium with a linear velocity of about 35 cm per second, and a split ratio of 1:5. [note—The split ratio can be modified in order to optimize sensitivity.] The column temperature is maintained at 40° for 20 minutes, then raised at a rate of 10° per minute to 240°, and maintained at 240° for 20 minutes. The injection port and detector temperatures are maintained at 140° and 250°, respectively. Chromatograph the Class 1 Standard Solution, the Class 1 System Suitability Solution, and the Class 2 Mixture A Standard Solution, and record the peak responses as directed for Procedure: the signal-to-noise ratio of 1,1,1-trichloroethane in the Class 1 Standard Solution is not less than 5; the signal-to-noise ratio of each peak in the Class 1 System Suitability Solution is not less than 3; and the resolution, R, between acetonitrile and methylene chloride in the Class 2 Mixture A Standard Solution is not less than 1.0.

Procedure—Separately inject (following one of the headspace operating parameters described in [Table 5](#)) equal volumes of headspace (about 1.0 mL) of the Standard Solution, the Test Solution, and the Spiked Test Solution into the chromatograph, record the chromatograms, and measure the responses for the major peaks. Calculate the amount, in ppm, of each residual solvent found in the article under test by the formula:

$$5(C/W)[rU / (rST - rU)]$$

in which C is the concentration, in μg per mL, of the appropriate USP Reference Standard in the Standard Solution; W is the weight, in g, of the article under test taken to prepare the

Test Stock Solution; and rU and rST are the peak responses of each residual solvent obtained from the Test Solution and the Spiked Test Solution, respectively.

#### water-insoluble articles

Procedure A— [note—Dimethyl sulfoxide may be substituted as an alternative solvent to dimethylformamide.]

Class 1 Standard Stock Solution— Transfer 1.0 mL of USP Class 1 Residual Solvents Mixture RS to a 100-mL volumetric flask previously filled with about 80 mL of dimethylformamide, dilute with dimethylformamide to volume, and mix. Transfer 1.0 mL of this solution to a 100-mL volumetric flask, previously filled with about 80 mL of dimethylformamide, dilute with dimethylformamide to volume, and mix (reserve a portion of this solution for the Class 1 System Suitability Solution). Transfer 1.0 mL of this solution to a 10-mL volumetric flask, dilute with dimethylformamide to volume, and mix.

Class 1 Standard Solution— Transfer 1.0 mL of Class 1 Standard Stock Solution to an appropriate headspace vial, containing 5.0 mL of water, apply the stopper, cap, and mix.

Class 2 Standard Stock Solutions— Transfer 1.0 mL of USP Residual Solvents Class 2—Mixture A RS to a 100-mL volumetric flask, previously filled with about 80 mL of dimethylformamide, dilute with dimethylformamide to volume, and mix. This is Class 2 Standard Stock Solution A. Transfer 0.5 mL of USP Residual Solvents Class 2—Mixture B RS to a 10-mL volumetric flask, dilute with dimethylformamide to volume, and mix. This is Class 2 Standard Stock Solution B.

Class 2 Mixture A Standard Solution— Transfer 1.0 mL of Class 2 Standard Stock Solution A to an appropriate headspace vial, containing 5.0 mL of water, apply the stopper, cap, and mix.

Class 2 Mixture B Standard Solution— Transfer 1.0 mL of Class 2 Standard Stock Solution B to an appropriate headspace vial, containing 5.0 mL of water, apply the stopper, cap, and mix.

Test Stock Solution— Transfer about 500 mg of the article under test, accurately weighed, to a 10-mL volumetric flask, dissolve in and dilute with dimethylformamide to volume, and mix.

Test Solution— Transfer 1.0 mL of Test Stock Solution to an appropriate headspace vial, containing 5.0 mL of water, apply the stopper, cap, and mix.

Class 1 System Suitability Solution— Mix 5 mL of Test stock solution with 0.5 mL of the intermediate dilution reserved from Class 1 Standard Stock Solution. Transfer 1.0 mL of this solution to an appropriate headspace vial, containing 5.0 mL of water, apply the stopper, cap, and mix.

Chromatographic System (see [Chromatography](#) 621) — The gas chromatograph is equipped with a flame-ionization detector, a 0.53-mm × 30-m wide-bore column coated with a 3.0-μm layer of phase G43. The carrier gas is helium with a linear velocity of about 35 cm per second, and a split ratio of 1:3 [note—Split ratio can be modified in order to optimize sensitivity.] The column temperature is maintained at 40° for 20 minutes, then raised at a rate of 10° per minute to 240°, and maintained at 240° for 20 minutes. The injection port and detector temperatures are maintained at 140° and 250°, respectively. Chromatograph the Class 1 Standard Solution, Class 1 System Suitability Solution, and Class 2 Mixture A Standard Solution, and record the peak responses as directed for Procedure: the signal-to-noise ratio of 1,1,1-trichloroethane in the Class 1 Standard Solution is not less than 5; the signal-to-noise ratio of each peak in the Class 1 System Suitability Solution is not less than 3; and the resolution, R, between acetonitrile and methylene chloride in the Class 2 Mixture A Standard Solution is not less than 1.0.

Procedure— Separately inject (use headspace operating parameters 3 in [Table 5](#) with a vial pressure of 10 psi) equal volumes of headspace (about 1.0 mL) of the Class 1 Standard Solution, Class 2 Mixture A Standard Solution, Class 2 Mixture B Standard Solution, and Test Solution into the chromatograph, record the chromatograms, and measure the responses for the major peaks. If a peak response of any peak, other than a peak for 1,1,1-trichloroethane, in the Test Solution is greater than or equal to a corresponding peak in either the Class 1 Standard Solution or either of the two Class 2 Mixture Standard Solutions, or a peak response of 1,1,1-trichloroethane is greater than or equal to 150 times the peak response corresponding to 1,1,1-trichloroethane in the Class 1 Standard Solution, proceed to Procedure B to verify the identity of the peak; otherwise the article meets the requirements of this test.

#### Procedure B—

Class 1 Standard Stock Solution, Class 1 Standard Solution, Class 1 System Suitability Solution, Class 2 Standard Stock Solutions, Class 2 Mixture A Standard Solution, and Class 2 Mixture B Standard Solution, Test Stock Solution, and Test Solution— Proceed as directed for Procedure A.

Chromatographic System— Proceed as directed for Procedure B under Water-Soluble Articles with a split ratio of 1:3 [note—The split ratio can be modified in order to optimize sensitivity.]

Procedure— Separately inject (use headspace operating parameters 3 in [Table 5](#) with a vial pressure of 10 psi) equal volumes of headspace (about 1.0 mL) of the Class 1 Standard Solution, Class 2 Mixture A Standard Solution, Class 2 Mixture B Standard Solution, and Test Solution, into the chromatograph, record the chromatograms, and measure the responses for the major peaks. If the peak response(s) in Test Solution of the peak(s) identified in Procedure A is/are greater than or equal to a corresponding peak(s) in either the Class 1 Standard Solution or any of the two Class 2 Mixture Standard Solutions, proceed to Procedure C to quantify the peak(s); otherwise the article meets the requirements of this test.

#### Procedure C—

Class 1 Standard Stock Solution, Class 1 Standard Solution, Class 1 System Suitability Solution, Class 2 Standard Stock Solution A, and Class 2 Mixture A Standard Solution— Proceed as directed for Procedure A.

Standard Stock Solution— [note—Prepare a separate Standard Solution for each peak identified and verified by Procedures A and B.] Transfer an accurately measured volume of each individual USP Reference Standard corresponding to each residual solvent peak identified and verified by Procedures A and B to a suitable container, and dilute quantitatively, and stepwise if necessary, with water to obtain a solution having a final concentration of 1/20 of the value stated in [Table 1](#) or [Table 2](#) (under Concentration Limit).

Standard Solution— Transfer 1.0 mL of the Standard Stock Solution to an appropriate headspace vial, containing 5.0 mL of water, apply the stopper, cap, and mix.

Test Stock Solution— Proceed as directed for Procedure A.

Test Solution— Transfer 1.0 mL of the Test Stock Solution to an appropriate headspace vial, containing 5.0 mL of water, apply the stopper, cap, and mix.

Spiked Test Solution— [note—Prepare a separate Spiked Test Solution for each peak identified and verified by Procedures A and B.] Transfer 1.0 mL of Test Stock Solution to an appropriate headspace vial, add 1 mL of Standard Stock Solution and 4.0 mL of water, apply the stopper, cap, and mix.

Chromatographic System— Proceed as directed for Procedure C under Water-Soluble Articles.

Procedure— Separately inject (use headspace operating parameters 3 in [Table 5](#) with a vial pressure of 10 psi) equal volumes of headspace (about 1.0 mL) of the Standard Solution, Test Solution, and Spiked Test Solution into the chromatograph, record the chromatograms, and measure the responses for the major peaks. Calculate the amount, in ppm, of each residual solvent found in the article under test by the formula:

$$10(C/W)[rU / (rST - rU)]$$

in which C is the concentration, in  $\mu\text{g}$  per mL, of the appropriate USP Reference Standard in the Standard Solution; W is the weight, in g, of the article under test taken to prepare the Test Stock Solution; and rU and rST are the peak responses of each residual solvent obtained from Test Solution and Spiked Test Solution, respectively.

#### Class 3 Residual Solvents

If Class 3 solvents are present, the level of residual solvents may be determined as directed under [Loss on Drying](#) 731 when the monograph for the article under test contains a loss on drying procedure, or a specific determination of the solvent may be made. If there is no loss on drying procedure in the monograph for the article under test or if a Class 3 solvent limit in an individual monograph is greater than 50 mg per day (corresponding to 5000 ppm or 0.5% under Option 1), the individual Class 3 residual solvent or solvents present in the article under test should be identified and quantified, and the procedures as described above, with appropriate modifications to the standard solutions, are to be applied wherever possible. Otherwise an appropriate validated procedure is to be employed. USP Reference Standards, where available, should be used in these procedures. A flow diagram for the application of residual solvent limit tests is shown in [Figure 1](#).

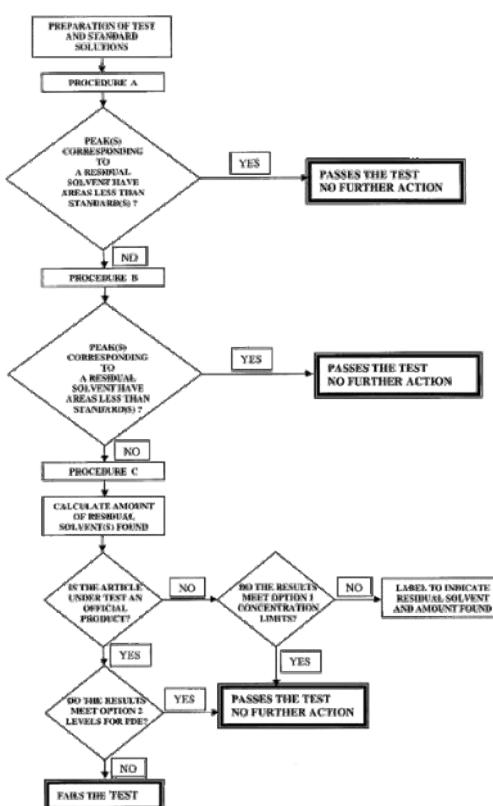

Figure 1. Diagram relating to the identification of residual solvents and the application of limit tests.

#### OTHER ANALYTICAL PROCEDURES

The following procedures, with any necessary variations, are used where specified in the individual monographs.

##### Method I

A gas chromatograph capable of temperature programming and equipped with a wide-bore, wall-coated open tubular column and a flame-ionization detector is used in the following procedure.

**Standard Solution**— Prepare a solution, in organic-free water, or the solvent specified in the monograph, containing in each mL, 12.0 µg of methylene chloride, 7.6 µg of 1,4-dioxane, 1.6 µg of trichloroethylene, and 1.2 µg of chloroform. [note—Prepare fresh daily.]

**Test Solution**— Dissolve in organic-free water, or the solvent specified in the monograph, an accurately weighed portion of the material to be tested to obtain a final solution having a known concentration of about 20 mg of the test material per mL.

**Chromatographic System** (see [Chromatography](#) 621)— The gas chromatograph is equipped with a flame-ionization detector, a 0.53-mm × 30-m fused silica analytical column coated with a 5-µm chemically cross-linked G27 stationary phase and a 0.53-mm × 5-m silica guard column deactivated with phenylmethyl siloxane. The carrier gas is helium with a linear velocity of about 35 cm per second. [note—When a makeup gas is used, nitrogen is recommended.] The injection port temperature and the detector temperature are maintained at 70° and 260°, respectively. The column temperature is programmed as follows. Initially, the column temperature is maintained at 35° for 5 minutes, then increased at a rate of 8° per minute to 175°, followed by an increase at a rate of 35° per minute to 260°, and maintained at 260° for at least 16 minutes.

Inject the Standard Solution, and record the peak responses as directed for Procedure: a suitable system is one that yields chromatograms in which all of the components in the Standard Solution are resolved; the resolution, R, between any two components is not less than 1.0; and the relative standard deviation of the individual peak responses from replicate injections is not more than 15%.

**Procedure**— Separately inject equal volumes (about 1 µL) of the Standard Solution and the Test Solution into the chromatograph, record the chromatograms, and measure the peak responses.

Identify, on the basis of retention time, any peaks present in the chromatogram of the Test Solution. The identity and peak response in the chromatogram may be established as being from any of the organic volatile impurities listed in the table shown below or from some other volatile impurity eluting with a comparable retention time as determined by mass spectrometric relative abundance procedures or by the use of a second validated column containing a different stationary phase.

Unless otherwise specified in the individual monograph, the amount of each organic volatile impurity present in the material does not exceed the limit given in the table shown below.

Organic Volatile Impurity	Limit (µg per g)
Chloroform	60
1,4-Dioxane	380
Methylene Chloride	600
Trichloroethylene	80

##### Method IV

**Standard Solution**— Prepare as directed for Standard Solution in Method I. Pipet 5 mL of the solution into a vial fitted with a septum and crimp cap, containing 1 g of anhydrous sodium sulfate, and seal. Heat the sealed vial at 80° for 60 minutes.

**Test Solution**— Transfer 100 mg, accurately weighed, of the material under test to a vial, add 5.0 mL of water, or the solvent specified in the monograph, and 1 g of anhydrous sodium sulfate, and seal with a septum and crimp cap. Heat the sealed vial at 80° for 60 minutes, or as specified in the individual monograph.

**Chromatographic System and Procedure**— [note—The use of headspace apparatuses that automatically transfer a measured amount of headspace is allowed. Also, the use of a

guard column in this headspace procedure is not necessary.] Proceed as directed for Method V, except to inject, using a heated gas-tight syringe, 1 mL of the headspace.

#### Method V

Standard Solution and Test Solution— Prepare as directed for Method I.

Chromatographic System (see [Chromatography \(621\)](#))—The gas chromatograph is equipped with a flame-ionization detector, a 0.53-mm × 30-m fused silica analytical column coated with a 3.0-μm G43 stationary phase, and a 0.53-mm × 5-m silica guard column deactivated with phenylmethyl siloxane. The carrier gas is helium with a linear velocity of about 35 cm per second. The injection port and detector temperatures are maintained at 140° and 260°, respectively. The column temperature is programmed according to the following steps. It is maintained at 40° for 20 minutes, then increased rapidly to 240°, and maintained at 240° for 20 minutes.

Inject the Standard Solution, and record the peak responses as directed for Procedure: a suitable system is one that yields chromatograms in which all of the components in the Standard Solution are resolved; the resolution, R, between any two components is not less than 3; and the relative standard deviation of the individual peak responses from replicate injections is not more than 15%.

Procedure— Proceed as directed for Method I, the injection volume being about 1 μL.

#### Method VI

Standard Solution and Test Solution— Prepare as directed for Method I.

Chromatographic System (see [Chromatography \(621\)](#))—The gas chromatograph is equipped with a flame-ionization detector. The column and column temperature conditions, as chosen from the list below (see [Table 6](#)), are specified in the individual monograph. The carrier gas, linear velocity or flow rate, and detector and injection port temperatures are appropriate to the column dimensions and column temperatures chosen from the list below.

Inject the Standard Solution, and record the peak responses as directed for Procedure: a suitable system is one that yields the chromatograms in which all of the components in the Standard Solution are resolved; the resolution, R, between any two components is not less than 1.0; and the relative standard deviation of the individual peak responses from replicate injections is not more than 15%.

Procedure— Proceed as directed for Method I, the injection volume being about 1 μL.

Table 6. Chromatographic Conditions for Method VI

Chromatographic Conditions	USP Column Designation	Column Size	Column Temperature
A	S3	3-mm × 2-m	190°
B	S2	3-mm × 2.1-m	160°
C	G16	0.53-mm × 30-m	40°
D	G39	3-mm × 2-m	65°
E	G16	3-mm × 2-m	70°
F	S4	2-mm × 2.5-m	Hold 120° (35 min.) Gradient 120°–200° (2°/min.) Hold 20 min.
H	G14	2-mm × 2.5-m	Hold 45° (3 min.) Gradient 45°–120° (8°/min.) Hold 15 min.
I	G27	0.53-mm × 30-m	Hold 35° (5 min.) 35°–175° (8°/min.) 175°–260° (35°/min.) Hold 16 min.
J	G16	0.33-mm × 30-m	Hold 50° (20 min.) 50°–165° (6°/min.) Hold 20 min.

#### GLOSSARY

Acceptable daily intake (ADI): The maximum acceptable intake of toxic chemicals per day. This term is used by the World Health Organization (WHO).

Genotoxic carcinogens: Carcinogens that produce cancer by affecting genes or chromosomes.

Lowest-observed-effect level (LOEL): The lowest dose of a substance in a study or group of studies that produces biologically significant increases in frequency or severity of any effects in exposed humans or animals.

Modifying factor: A factor determined by professional judgment of a toxicologist and applied to bioassay data so that the data can be safely related to humans.

Neurotoxicity: The ability of a substance to cause adverse effects on the nervous system.

No-observed-effect level (NOEL): The highest dose of a substance at which there are no biologically significant increases in frequency or severity of any effects in exposed humans or animals.

Permitted daily exposure (PDE): The maximum acceptable intake per day of a residual solvent in pharmaceutical products.

Reversible toxicity: The occurrence of harmful effects that are caused by a substance and that disappear after exposure to the substance ends.

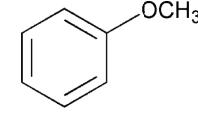

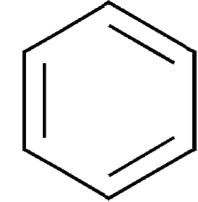

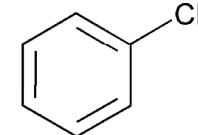

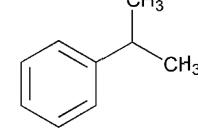

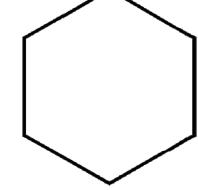

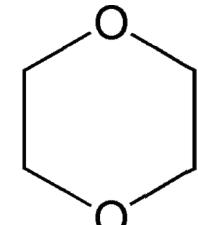

Strongly suspected human carcinogen: A substance for which there is no epidemiological evidence of carcinogenesis but for which there are positive genotoxicity data and clear evidence of carcinogenesis in rodents.

Teratogenicity: The occurrence of structural malformations in a developing fetus when a substance is administered during pregnancy.

Tolerable daily intake (TDI): Tolerable daily exposure to toxic chemicals. Term used by the International Program on Chemical Safety (IPCS).

#### APPENDIX 1. LIST OF RESIDUAL SOLVENTS INCLUDED IN THIS GENERAL CHAPTER

Solvent	Other Names	Structure	Class
Acetic acid	Ethanoic acid	CH <sub>3</sub> COOH	Class 3
Acetone	2-Propanone Propan-2-one	CH <sub>3</sub> COCH <sub>3</sub>	Class 3

Cetonitrile		CH3CN	
Anisole	Methoxybenzene		Class 2 Class 3
Benzene	Benzol		Class 1
1-Butanol	n-Butyl alcohol Butan-1-ol	CH3(CH2)3OH	Class 3
2-Butanol	sec-Butyl alcohol Butan-2-ol	CH3CH2CH(OH)CH3	Class 3
Butyl acetate	Acetic acid butyl ester	CH3COO(CH2)3CH3	Class 3
tert-Butylmethyl ether	2-Methoxy-2-methylpropane	(CH3)3COCH3	Class 3
Carbon tetrachloride	Tetrachloromethane	CCl4	Class 1
Chlorobenzene			Class 2
Chloroform	Trichloromethane	CHCl3	Class 2
Cumene	Isopropylbenzene (1-Methylethyl)benzene		Class 3
Cyclohexane	Hexamethylene		Class 2
1,2-Dichloroethane	sym-Dichloroethane Ethylene dichloride Ethylene chloride	CH2ClCH2Cl	Class 1
1,1-Dichloroethene	1,1-Dichloroethylene Vinylidene chloride	H2C=CCl2	Class 1
1,2-Dichloroethene	1,2-Dichloroethylene Acetylene dichloride	CHCl=CHCl	Class 2
1,2-Dimethoxyethane	Ethyleneglycol dimethyl ether Monoglyme Dimethyl cellosolve	H3COCH2CH2OCH3	Class 2
N,N-Dimethylacetamide	DMA	CH3CON(CH3)2	Class 2
N,N-Dimethylformamide	DMF	HCON(CH3)2	Class 2
Dimethyl sulfoxide	Methylsulfinylmethane Methyl sulfoxide DMSO	(CH3)2SO	Class 3
1,4-Dioxane	p-Dioxane [1,4]Dioxane		Class 2
Ethanol	Ethyl alcohol	CH3CH2OH	Class 3
2-Ethoxyethanol	Cellosolve	CH3CH2OCH2CH2OH	Class 2
Ethyl acetate	Acetic acid ethyl ester	CH3COOCH2CH3	Class 3

Methylene glycol	1,2-Dihydroxyethane 1,2-Ethanediol	HOCH2CH2OH	Class 2
Ethyl ether	Diethyl ether Ethoxyethane 1,1'-Oxybisethane	CH3CH2OCH2CH3	Class 3
Ethyl formate	Formic acid ethyl ester	HCOOCH2CH3	Class 3
Formamide	Methanamide	HCONH2	Class 2
Formic acid		HCOOH	Class 3
Heptane	n-Heptane	CH3(CH2)5CH3	Class 3
Hexane	n-Hexane	CH3(CH2)4CH3	Class 2
Isobutyl acetate	Acetic acid isobutyl ester	CH3COOCH2CH(CH3)2	Class 3
Isopropyl acetate	Acetic acid isopropyl ester	CH3COOCH(CH3)2	Class 3
Methanol	Methyl alcohol	CH3OH	Class 2
2-Methoxyethanol	Methyl cellosolve	CH3OCH2CH2OH	Class 2
Methyl acetate	Acetic acid methyl ester	CH3COOCH3	Class 3
3-Methyl-1-butanol	Isoamyl alcohol Isopentyl alcohol 3-Methylbutan-1-ol	(CH3)2CHCH2CH2OH	Class 3
Methylbutylketone	2-Hexanone Hexan-2-one	CH3(CH2)3COCH3	Class 2

\* Usually 60% m-xylene, 14% p-xylene, 9% o-xylene with 17% ethyl benzene.

## APPENDIX 2. ADDITIONAL BACKGROUND

### A2.1. Environmental Regulation of Organic Volatile Solvents

Several of the residual solvents frequently used in the production of pharmaceuticals are listed as toxic chemicals in Environmental Health Criteria (EHC) monographs and in the Integrated Risk Information System (IRIS). The objectives of such groups as the International Programme on Chemical Safety (IPCS), the United States Environmental Protection Agency (EPA), and the United States Food and Drug Administration (FDA) include the determination of acceptable exposure levels. The goal is maintenance of environmental integrity and protection of human health against the possible deleterious effects of chemicals resulting from long-term environmental exposure. The procedures involved in the estimation of maximum safe exposure limits are usually based on long-term studies. When long-term study data are unavailable, shorter term study data can be used with modification of the approach, such as use of larger safety factors. The approach described therein relates primarily to long-term or lifetime exposure of the general population in the ambient environment (i.e., ambient air, food, drinking water, and other media).

### A2.2. Residual Solvents in Pharmaceuticals

Exposure limits in this General Chapter are established by referring to methodologies and toxicity data described in EHC and IRIS monographs. However, the following specific assumptions about residual solvents to be used in the synthesis and formulation of pharmaceutical products should be taken into account in establishing exposure limits.

1. Patients (not the general population) use pharmaceuticals to treat their diseases or for prophylaxis to prevent infection or disease.
2. The assumption of lifetime patient exposure is not necessary for most pharmaceutical products but may be appropriate as a working hypothesis to reduce risk to human health.
3. Residual solvents are unavoidable components in pharmaceutical production and will often be a part of medicinal products.
4. Residual solvents should not exceed recommended levels except in exceptional circumstances.
5. Data from toxicological studies that are used to determine acceptable levels for residual solvents should have been generated using appropriate protocols such as those described, for example, by the Organization for Economic Cooperation and Development (OECD), EPA, and the FDA Red Book.

## APPENDIX 3. PROCEDURES FOR ESTABLISHING EXPOSURE LIMITS

The Gaylor-Kodell method of risk assessment (Gaylor, D. W. and Kodell, R. L. Linear Interpolation Algorithm for Low Dose Assessment of Toxic Substance. *Journal of Environmental Pathology and Toxicology*, 4:305, 1980) is appropriate for Class 1 carcinogenic solvents. Only in cases where reliable carcinogenicity data are available should extrapolation by the use of mathematical models be applied to setting exposure limits. Exposure limits for Class 1 residual solvents could be determined with the use of a large safety factor (i.e., 10,000 to 100,000) with respect to the no-observed-effect level (NOEL). Detection and quantification of these residual solvents should be performed by state-of-the-art analytical techniques.

Acceptable exposure levels in this General Chapter for Class 2 residual solvents were established by calculation of PDE values according to the procedures for setting exposure limits in pharmaceuticals (page 5748 of PF 15(6) [Nov.–Dec. 1989]), and the method adopted by IPCS for Assessing Human Health Risk of Chemicals (Environmental Health Criteria 170, WHO, 1994). These procedures are similar to those used by the U.S. EPA (IRIS) and the U.S. FDA (Red Book) and others. The method is outlined here to give a better understanding of the origin of the PDE values. It is not necessary to perform these calculations in order to use the PDE values presented in [Table 2](#) of this document.

PDE is derived from the no-observed-effect level (NOEL), or the lowest-observed effect level (LOEL), in the most relevant animal study as follows:

$$PDE = \frac{NOEL \times \text{Weight Adjustment}}{F1 \times F2 \times F3 \times F4 \times F5} \quad (1)$$

The PDE is derived preferably from a NOEL. If no NOEL is obtained, the LOEL may be used. Modifying factors proposed here, for relating the data to humans, are the same kind of "uncertainty factors" used in Environmental Health Criteria (Environmental Health Criteria 170, WHO, Geneva, 1994) and "modifying factors" or "safety factors" in Pharmacopeial Forum. The assumption of 100 percent systemic exposure is used in all calculations regardless of route of administration.

The modifying factors are as follows:

F1 = A factor to account for extrapolation between species

F1 = 2 for extrapolation from dogs to humans

F1 = 2.5 for extrapolation from rabbits to humans

F1 = 3 for extrapolation from monkeys to humans

F1 = 5 for extrapolation from rats to humans

F1 = 10 for extrapolation from other animals to humans

F1 = 12 for extrapolation from mice to humans

F1 takes into account the comparative surface area to body weight ratios for the species concerned and for man. Surface area (S) is calculated as:

$$S = kM^{0.67} \quad (2)$$

in which M = body weight, and the constant k has been taken to be 10. The body weights used in the equation are those shown below in [Table A3-1](#).

F2 = A factor of 10 to account for variability between individuals. A factor of 10 is generally given for all organic solvents, and 10 is used consistently in this General Chapter.

F3 = A variable factor to account for toxicity studies of short-term exposure.

F3 = 1 for studies that last at least one half-lifetime (1 year for rodents or rabbits; 7 years for cats, dogs, and monkeys).

F3 = 1 for reproductive studies in which the whole period of organogenesis is covered.

F3 = 2 for a 6-month study in rodents, or a 3.5-year study in nonrodents.

F3 = 5 for a 3-month study in rodents, or a 2-year study in nonrodents.

F3 = 10 for studies of a shorter duration.

In all cases, the higher factor has been used for study durations between the time points (e.g., a factor of 2 for a 9-month rodent study).

F4 = A factor that may be applied in cases of severe toxicity, e.g., nongenotoxic carcinogenicity, neurotoxicity, or teratogenicity. In studies of reproductive toxicity, the following factors are used:

F4 = 1 for fetal toxicity associated with maternal toxicity

F4 = 5 for fetal toxicity without maternal toxicity

F4 = 5 for a teratogenic effect with maternal toxicity

F4 = 10 for a teratogenic effect without maternal toxicity

F5 = A variable factor that may be applied if the no-effect

level was not established.

When only a LOEL is available, a factor of up to 10 can be used depending on the severity of the toxicity. The weight adjustment assumes an arbitrary adult human body weight for either sex of 50 kilograms (kg). This relatively low weight provides an additional safety factor against the standard weights of 60 kg or 70 kg that are often used in this type of calculation. It is recognized that some adult patients weigh less than 50 kg; these patients are considered to be accommodated by the built-in safety factors used to determine a PDE. If the solvent was present in a formulation specifically intended for pediatric use, an adjustment for a lower body weight would be appropriate.

As an example of the application of this equation, consider a toxicity study of acetonitrile in mice that is summarized in *Pharneuropa*, Vol. 9, No. 1, Supplement, April 1997, page S24.

The NOEL is calculated to be 50.7 mg kg<sup>-1</sup> day<sup>-1</sup>. The PDE for acetonitrile in this study is calculated as follows:

$$PDE = \frac{50.7 \text{ mg kg}^{-1} \text{ day}^{-1} \times 50 \text{ kg}}{12 \times 10 \times 5 \times 1 \times 1} = 4.22 \text{ mg day}^{-1}$$

In this example,

F1 = 12 to account for the extrapolation from mice to humans

F2 = 10 to account for differences between individual humans

F3 = 5 because the duration of the study was only 13 weeks

F4 = 1 because no severe toxicity was encountered

F5 = 1 because the no-effect level was determined

#### A3-1. Values Used in the Calculations in This Document

Rat body weight	425 g
Pregnant rat body weight	330 g
Mouse body weight	28 g
Pregnant mouse body weight	30 g
Guinea-pig body weight	500 g
Rhesus monkey body weight	2.5 kg
Rabbit body weight (pregnant or not)	4 kg
Beagle dog body weight	11.5 kg
Rat respiratory volume	290 L/day
Mouse respiratory volume	43 L/day
Rabbit respiratory volume	1440 L/day

Guinea-pig respiratory volume	430 L/day
Human respiratory volume	28,800 L/day
Dog respiratory volume	9000 L/day
Monkey respiratory volume	1150 L/day
Mouse water consumption	5 mL/day
Rat water consumption	30 mL/day
Rat food consumption	30 g/day

The equation for an ideal gas,  $PV = nRT$ , is used to convert concentrations of gases used in inhalation studies from units of ppm to units of mg/L or mg/m<sup>3</sup>. Consider as an example the rat reproductive toxicity study by inhalation of carbon tetrachloride (molecular weight 153.84) summarized in Pharmeuropa, Vol. 9, No. 1, Supplement, April 1997, page S9.

$$\frac{n}{V} = \frac{P}{RT} = \frac{300 \times 10^{-6} \text{ atm} \times 153.84 \text{ g/mol}^{-1}}{0.082 \text{ L atm K}^{-1} \text{ mol}^{-1} \times 298 \text{ K}} = \frac{46.15 \text{ mg}}{24.45 \text{ L}} = 1.89 \text{ mg/L}$$

The relationship 1000 L = 1 m<sup>3</sup> is used to convert to mg/m<sup>3</sup>.

#### 471 OXYGEN FLASK COMBUSTION

The oxygen flask combustion procedure is provided as the preparatory step in the determination of bromine, chlorine, iodine, selenium, and sulfur in some Pharmacopeial articles. Combustion of the material under test (usually organic) yields water-soluble inorganic products, which are analyzed for specific elements as directed in the individual monograph or general chapter.

The caution statement given for Procedure covers minimum safety precautions only, and serves to emphasize the need for exceptional care throughout.

**Apparatus**— The apparatus<sup>1</sup> consists of a heavy-walled conical, deeply lipped or cupped 500-mL flask (unless a larger flask is specified), fitted with a ground-glass stopper to which is fused a test specimen carrier consisting of heavy-gauge platinum wire and a piece of welded platinum gauze measuring about 1.5 × 2 cm.

Apparatus for Oxygen Flask Combustion

**Procedure**— [Caution—Wear safety glasses and use a suitable safety shield between yourself and the apparatus. Exercise care to ensure that the flask is scrupulously clean and free from even traces of organic solvents.] Weigh the substance, if a solid, on a piece of halide-free filter paper measuring about 4 cm square, and fold the paper to enclose it. Liquid substances are weighed in tared capsules, polycarbonate capsules<sup>1</sup> being used for liquids in volumes not exceeding 200 µL, and gelatin capsules being satisfactory for use for larger volumes. [note—Gelatin capsules may contain significant amounts of combined halide or sulfur. If such capsules are used, perform a blank determination, and make any necessary correction.] Place the specimen, together with a filter paper fuse-strip, in the platinum gauze specimen holder. Place the absorbing liquid specified in the individual monograph or general chapter in the flask, moisten the joint of the stopper with water, and flush the air from the flask with a stream of rapidly flowing oxygen, swirling the liquid to favor its taking up oxygen. [note—Saturation of the liquid with oxygen is essential for the successful performance of the combustion procedure.] Ignite the fuse-strip by suitable means. If the strip is ignited outside the flask, immediately plunge the specimen holder into the flask, invert the flask so that the absorption solution makes a seal around the stopper, and hold the stopper firmly in place. If the ignition is carried out in a closed system, the inversion of the flask may be omitted. After combustion is complete, shake the flask vigorously, and allow to stand for not less than 10 minutes with intermittent shaking. Then proceed as directed in the individual monograph or general chapter.

<sup>1</sup> A suitable apparatus [Catalog Nos. 6513-C20 (500-ml capacity) and 6513-C30 (1000-ml capacity)] and suitable capsules [Catalog No. 6513-84 (1000 capsules)] are obtainable from Thomas Scientific, 99 High Hill Road, Swedesboro, NJ 08085.

#### 481 RIBOFLAVIN ASSAY

The following procedure is suitable for preparations in which riboflavin is a constituent of a mixture of several ingredients. In employing it, keep the pH of solutions below 7.0, and protect the solutions from direct sunlight at all stages.

[USP Reference Standards](#) [11](#)—[USP Riboflavin RS](#).

Standard Riboflavin Stock Solution— To 50.0 mg of [USP Riboflavin RS](#), previously dried and stored protected from light in a desiccator over phosphorus pentoxide, add about 300 mL of 0.02 N acetic acid, and heat the mixture on a steam bath, with frequent agitation, until the riboflavin has dissolved. Then cool, add 0.02 N acetic acid to make 500 mL, and mix. Store under toluene in a refrigerator.

Dilute an accurately measured portion of this solution, using 0.02 N acetic acid, to a concentration of 10.0  $\mu$ g of the dried [USP Riboflavin RS](#) per mL, to obtain the Standard Riboflavin Stock Solution. Store under toluene in a refrigerator.

Standard Preparation— Dilute 10.0 mL of Standard Riboflavin Stock Solution with water in a 100-mL volumetric flask to volume, and mix. Each mL represents 1.0  $\mu$ g of [USP Riboflavin RS](#). Prepare fresh Standard Preparation for each assay.

Assay Preparation— Place an amount of the material to be assayed in a flask of suitable size, and add a volume of 0.1 N hydrochloric acid equal in mL to not less than 10 times the dry weight of the material in g, but the resulting solution shall contain not more than 100  $\mu$ g of riboflavin per mL. If the material is not readily soluble, comminute it so that it may be evenly dispersed in the liquid. Then agitate vigorously, and wash down the sides of the flask with 0.1 N hydrochloric acid.

Heat the mixture in an autoclave at 121° to 123° for 30 minutes, and cool. If clumping occurs, agitate the mixture until the particles are evenly dispersed. Adjust the mixture, with vigorous agitation, to a pH of 6.0 to 6.5 with sodium hydroxide solution,<sup>1</sup> then add hydrochloric acid solution<sup>2</sup> immediately until no further precipitation occurs (usually at a pH of approximately 4.5, the isoelectric point of many of the proteins present). Dilute the mixture with water to make a measured volume that contains about 0.11  $\mu$ g of riboflavin in each mL, and filter through paper known not to adsorb riboflavin. To an aliquot of the filtrate add, with vigorous agitation, sodium hydroxide solution<sup>1</sup> to produce a pH of 6.6 to 6.8, dilute the solution with water to make a final measured volume that contains approximately 0.1  $\mu$ g of riboflavin in each mL, and if cloudiness occurs, filter again.

Procedure— To each of four or more tubes (or reaction vessels) add 10.0 mL of the Assay Preparation. To each of two or more of these tubes add 1.0 mL of the Standard Preparation, and mix, and to each of two or more of the remaining tubes add 1.0 mL of water, and mix. To each tube add 1.0 mL of glacial acetic acid, mix, then add, with mixing, 0.50 mL of potassium permanganate solution (1 in 25), and allow to stand for 2 minutes. To each tube add, with mixing, 0.50 mL of hydrogen peroxide solution, whereupon the permanganate color is destroyed within 10 seconds. Shake the tubes vigorously until excess oxygen is expelled. Remove any gas bubbles remaining on the sides of the tubes after foaming has ceased, by tipping the tubes so that the solution flows slowly from end to end.

In a suitable fluorophotometer, having an input filter of narrow transmittance range with a maximum at about 440 nm and an output filter of narrow transmittance range with a maximum at about 530 nm, measure the fluorescence of all tubes, designating the average reading from the tubes containing only the Assay Preparation as IU and the average from the tubes containing both the Assay Preparation and the Standard Preparation as IS. Then to each of one or more tubes of each kind add, with mixing, 20 mg of sodium hydrosulfite, and within 5 seconds again measure the fluorescence, designating the average reading as IB.

Calculation— Calculate the quantity, in mg, of C17H20N4O6 in each mL of the Assay Preparation taken by the formula:

$$0.0001(IU - IB) / (IS - IU)$$

Calculate the quantity, in mg, of C17H20N4O6 in each capsule or tablet.

\* The concentrations of the hydrochloric acid and sodium hydroxide solutions used are not stated in each instance because these concentrations may be varied depending upon the amount of material taken for assay, volume of test solution, and buffering effect of material.

Auxiliary Information— Please [check for your question in the FAQs](#) before contacting USP.

## 501 SALTS OF ORGANIC NITROGENOUS BASES

Standard Preparation— Unless otherwise directed, prepare a solution in dilute sulfuric acid (1 in 70) containing, in each mL, about 500  $\mu$ g of the specified USP Reference Standard, calculated on the anhydrous basis, and accurately weighed.

Assay Preparation— If the dosage form is a tablet, weigh and finely powder not less than 20 tablets, weigh accurately a portion of the powder, equivalent to about 25 mg of the active ingredient, and transfer to a 125-mL separator; or, if the dosage form is a liquid, transfer a volume of it, equivalent to about 25 mg of the active ingredient and accurately measured, to a 125-mL separator. Then to the separator add 20 mL of dilute sulfuric acid (1 in 350), and shake vigorously for 5 minutes. Add 20 mL of ether, shake carefully, and filter the acid phase into a second 125-mL separator. Shake the ether phase with two 10-mL portions of dilute sulfuric acid (1 in 350), filter each portion of acid into the second separator, and discard the ether. To the acid extract add 10 mL of [sodium hydroxide TS](#) and 50 mL of ether, shake carefully, and transfer the aqueous phase to a third 125-mL separator containing 50 mL of ether. Shake the third separator carefully, and discard the aqueous phase. Wash the two ether solutions, in succession, with a single 20-mL portion of water, and discard the water. Extract each of the two ether solutions with 20-, 20-, and 5-mL portions of dilute sulfuric acid (1 in 70), in the order listed, but each time extract first the ether solution in the third separator and then that in the second separator. Combine the acid extracts in a 50-mL volumetric flask, dilute with the acid to volume, and mix.

note—Hexane or heptane may be substituted for ether if the distribution ratio of the nitrogenous base between water and hexane, or between water and heptane, favors complete extraction by the organic phase.

Procedure— Unless otherwise directed, dilute 5.0 mL each of the Standard Preparation and the Assay Preparation with dilute sulfuric acid (1 in 70) to 100.0 mL, and determine the absorbance of each solution at the specified wavelength, using dilute sulfuric acid (1 in 70) as the blank. Designate the absorbance of the solution from the Standard Preparation as AS and that from the Assay Preparation as AU, and calculate the result of the assay as directed in the individual monograph.

Auxiliary Information— Please [check for your question in the FAQs](#) before contacting USP.

USP32-NF27 Page 176

## 503 ACETIC ACID IN PEPTIDES

The following procedure is to be used to determine the amount of acetate or acetic acid in peptides. Acetate is a common counterion in many peptide preparations.

USP Reference Standards (11) — [USP Glacial Acetic Acid RS](#).

Strong Sodium Hydroxide Solution— Dissolve 42 g of sodium hydroxide in water, and dilute with water to 100 mL.

Solution A— Add 0.7 mL of phosphoric acid to 1000 mL of water, and adjust with Strong Sodium Hydroxide Solution to a pH of 3.0.

Solution B— Use methanol.

Diluent— Prepare a mixture of Solution A and Solution B (95:5).

Standard Solution— [note—The concentration can be adjusted depending on the amount of acetate or acetic acid expected to be present in the test material.] Dissolve an accurately weighed quantity of USP Acetic Acid RS in Diluent to obtain a solution having a known concentration of about 0.1 mg per mL.

Test Solution— Prepare as directed in the individual monograph. The amount of material used can be adapted depending on the amount of acetic acid expected.

Chromatographic System (see [Chromatography \(621\)](#))— The liquid chromatograph is equipped with a 210-nm detector and a 4.6-mm × 25-cm column that contains not greater than 5-μm packing L1. The flow rate is about 1.2 mL per minute. The chromatograph is programmed as follows.

Time (minutes)	Solution A (%)	Solution B (%)	Elution
0	95	5	equilibration
0-5	95	5	isocratic
5-10	95→50	5→50	linear gradient
10-20	50	50	isocratic
20-22	50→95	50→5	linear gradient

Chromatograph the Standard Solution, and record the peak responses as directed for Procedure: the retention time of acetic acid is between 3 and 4 minutes; and the relative standard deviation for replicate injections is not more than 5%.

Procedure— Separately inject equal volumes (about 10 μL) of the Standard Solution and the Test Solution into the chromatograph, record the chromatograms, and measure the responses for the acetic acid peaks. Calculate the percentage of acetic acid in the portion of test material taken by the formula:

$$100(CS / M)(rU / rS)$$

in which CS is the concentration of acetic acid in the Standard Solution; M is the concentration, in mg per mL, of the Test Solution, based on the weight of test material taken and the extent of dilution; and rU and rS are the acetic acid peak responses obtained from the Test Solution and the Standard Solution, respectively.

Auxiliary Information— Please [check for your question in the FAQs](#) before contacting USP.

### 511 SINGLE-STEROID ASSAY

In the following procedure, the steroid to be assayed is separated from related foreign steroids and excipients by thin-layer chromatography and determined following recovery from the chromatogram.

Preparation of the Plate— Prepare a slurry from 30 g of chromatographic silica gel with a suitable fluorescing substance by the gradual addition, with mixing, of about 65 mL of a mixture of water and alcohol (5:2). Transfer the slurry to a clean, 20- × 20-cm plate, spread to make a uniform layer 250 μm thick, and allow to dry at room temperature for 15 minutes.

Heat the plate at 105° for 1 hour, and store in a desiccator.

Solvent A— Mix methylene chloride with methanol (180:16).

Solvent B— Mix chloroform with acetone (4:1).

Standard Preparation— Dissolve in a mixture of equal volumes of chloroform and alcohol a suitable quantity of the USP Reference Standard specified in the individual monograph, previously dried as directed (see [USP Reference Standards \(11\)](#)) and accurately weighed, to obtain a solution having a known concentration of about 2 mg per mL.

Assay Preparation— Prepare as directed in the individual monograph.

Procedure— Divide the area of the chromatographic plate into three equal sections, the left and right sections to be used for the Assay Preparation and the Standard Preparation, respectively, and the center section for the blank. Apply 200 μL each of the Assay Preparation and the Standard Preparation as streaks 2.5 cm from the bottom of the appropriate section of the plate. Dry the solution as it is being applied, with the aid of a stream of air. Using the Solvent specified in the individual monograph, develop the chromatogram in a suitable chamber, previously equilibrated and lined with absorbent paper, until the solvent front has moved 15 cm above the initial streaks.

Remove the plate, evaporate the solvent, and locate the principal band occupied by the Standard Preparation by viewing under UV light. Mark this band, as well as corresponding bands in the Assay Preparation and blank sections of the plate. Remove the silica gel from each band separately, either by scraping onto glazed weighing papers or by using a suitable vacuum collecting device, and transfer it to a glass-stoppered, 50-mL centrifuge tube. To each tube add 25.0 mL of alcohol, and shake for not less than 2 minutes. Centrifuge the tubes for 5 minutes, pipet 20 mL of the supernatant from each tube into a glass-stoppered, 50-mL conical flask, add 2.0 mL of a solution prepared by dissolving 50 mg of blue tetrazolium in

10 mL of methanol, and mix. Proceed as directed for Procedure under [Assay for Steroids](#) (351), beginning with "Then to each flask."

Auxiliary Information— Please [check for your question in the FAQs](#) before contacting USP.

## 521 SULFONAMIDES

### Identification of Individual Sulfonamides in Mixed Sulfonamides

note—The following instructions for preparations and procedure are applicable to all sulfonamides except sulfadiazine. When testing for sulfadiazine proceed in the same manner, except to use sulfadiazine preparations having one-half the designated concentration, and apply twice the designated volumes of sulfadiazine preparations to the chromatographic plates.

Standard Preparation— Transfer a quantity of the pertinent USP Reference Standard to a suitable glass-stoppered, conical flask, dissolve in methanol to obtain a solution having a concentration of about 2 mg per mL, and mix. A separate Standard Preparation is required for each sulfonamide present in mixed sulfonamides.

Test Preparation— Transfer a portion of the thoroughly mixed suspension or finely powdered tablets, equivalent to about 100 mg of each sulfonamide, to a 50-mL volumetric flask containing 10 mL of [ammonia TS](#), and swirl. Add methanol to volume, mix, filter, and use the filtrate in the Procedure.

Preparation of Chromatographic Plates— Prepare three identical chromatographic plates according to the following directions. Apply separately, and 2 cm apart along a spotting line 1.5 cm from the bottom of the plate and parallel to it, 2  $\mu$ L of each Standard Preparation and 2  $\mu$ L of the Test Preparation to a suitable thin-layer chromatographic plate (see [Chromatography](#) (621)) coated with a 0.25-mm layer of chromatographic silica gel mixture. On another spot, 2 cm along the spotting line from the application of the Test Preparation, apply, successively, 2  $\mu$ L of each Standard Preparation to obtain a mixed standard. Dry the spots immediately with the aid of a stream of nitrogen.

Procedure— Prepare a chromatographic chamber lined with filter paper and containing a solvent system consisting of ethyl acetate, methanol, and a 1 in 4 aqueous solution of ammonium hydroxide (17:6:5), and allow to equilibrate for 1 hour. Similarly prepare a second chamber to contain a solvent system consisting of solvent hexane, chloroform, and butyl alcohol (1:1:1), and a third chamber to contain a solvent system consisting of chloroform and methanol (95:5). Place one prepared chromatographic plate in each equilibrated chamber, and develop the chromatograms until the solvent front has moved about three-fourths of the length of each plate. Remove each plate from its developing chamber, mark the solvent front, and allow the solvent to evaporate. Locate the spots on the plates by viewing under short-wavelength UV light. Spray the plates with a 1 in 100 solution of p-dimethylaminobenzaldehyde in dilute hydrochloric acid (1 in 20), and heat at 110° for 5 minutes or until bright yellow spots become visible. The RF values of the yellow spots obtained from each Test Preparation correspond to those obtained from the mixed Standard Preparations on the respective plates. The individual sulfonamides may be identified by comparison of the RF values of the yellow spots obtained from the Test Preparations and individual Standard Preparations on the respective plates.

### Determination of Individual Sulfonamides in Mixed Sulfonamides

Standard Preparation— A separate Standard Preparation is required for each sulfonamide being determined. Transfer about 50 mg, accurately weighed, of the pertinent USP Reference Standard to a 50-mL volumetric flask containing 1.5 mL of ammonium hydroxide, add methanol, dissolve in methanol, dilute with methanol to volume, and mix. Transfer 1.0 mL of this solution to a 100-mL volumetric flask, add dilute hydrochloric acid (1 in 100) to volume, and mix. [note—Retain the methanol solutions for the Mixed Standard Preparation. The methanol solutions are stable for at least 1 week, and the acid solutions for at least 1 month.]

Mixed Standard Preparation— Transfer 1.0 mL of each methanol solution, prepared as required for each Standard Preparation, to a small glass-stoppered flask, and mix. [note—This Standard is used to identify the components of the Assay Preparation on the chromatogram.]

Assay Preparation— Prepare as directed in the individual monograph.

Procedure— Prepare the necessary number of chromatographic sheets (Whatman No. 1 filter paper, or equivalent), about 20  $\times$  20 cm in size, by drawing a pencil line parallel to and 2.5 cm from one edge of the paper. Mark the line at points 2.5 and 5 cm from each edge of the paper. Impregnate the paper by dipping it in the immobile solvent (prepared fresh by dissolving 30 mL of redistilled formamide in 70 mL of acetone) for 30 seconds. Remove the paper, drain for 10 seconds, and blot between filter paper. Place the impregnated paper on dry filter paper, and air-dry for 3 to 5 minutes. With a micropipet, and with repeated applications, streak 100  $\mu$ L of the Assay Preparation along the starting line, applying the volume in five streaks of about 20  $\mu$ L each and evaporating the solvent with a gentle stream of nitrogen between applications. [note—Make the streak as narrow as possible along the starting line, and keep within the 5-cm border.] Rinse the tip of the pipet with a drop of methanol-ammonia TS mixture (9:1), and then streak the rinse along the starting line between the 5- and 2.5-cm points at the right edge. Repeat the rinsing with two additional drops, and then blow out the pipet.

Apply 10  $\mu$ L of the Mixed Standard Preparation at the mark 2.5 cm from the left edge.

Place 50 mL of methylene chloride (mobile solvent) in a tray in a 23-  $\times$  23-  $\times$  7.5-cm chromatographic chamber arranged for ascending chromatography (see [Chromatography](#) (621)), and allow the chamber to equilibrate for about 15 minutes. Remove the cover, place from 7 to 10 mL of water in a second tray, and without delay, suspend the prepared chromatographic paper sheet so that it dips into the mobile solvent. Cover and seal the chamber, and allow the chromatogram to develop for 1 hour. Remove the paper from the chamber, and allow to air-dry for 5 minutes. Place the chromatogram on a dry sheet of filter paper, and view it under short-wavelength UV light. [note—Conduct the following identification and marking without delay to avoid excessive exposure of the sulfonamide spots to UV irradiation.] Identify and mark the respective spots by matching RF values with those of the spots produced by the Mixed Standard Preparation. [note—Sulfadiazine and sulfamerazine are chromatographed with increasing RF, respectively.]

Cut the marked zones from the paper, cut each zone into five or six pieces, and place the pieces from each spot in separate, glass-stoppered, 50-mL flasks. Add 20.0 mL of dilute hydrochloric acid (1 in 100) to each flask, and allow to stand for about 30 minutes, swirling each flask at least five times during this period. Filter the solutions through dry glass wool into separate test tubes, discarding the first 5 mL of the filtrate. Transfer 5.0 mL of the subsequent filtrate from each solution into separate 10-mL volumetric flasks. Transfer 3.0 mL of each required Standard Preparation into separate, 10-mL volumetric flasks. To each flask, and to a blank flask containing 5 mL of dilute hydrochloric acid (1 in 100), add 1.0 mL of sodium nitrite solution (1 in 1000) and 0.10 mL of hydrochloric acid, and allow to stand for 5 minutes with frequent swirling. To each flask add 1.0 mL of ammonium sulfamate solution (1 in 200), and allow to stand for 5 minutes, swirling frequently. Finally, to each flask add 1.0 mL of freshly prepared N-(1-naphthyl)ethylenediamine dihydrochloride solution (1 in 1000), mix, dilute with water to volume, and mix. Allow each solution to stand between 15 and 60 minutes, and then concomitantly determine the absorbances of the solutions, in 1-cm cells, recording the spectra from 440 to 700 nm, with a suitable spectrophotometer, using the blank to set the instrument. Draw a baseline, and determine the corrected absorbance for each solution at the wavelength of maximum absorbance at about 545 nm.

Calculate the concentration, in mg per mL, of each sulfonamide in the Assay Preparation by the formula:

$$0.12C(AU / AS)$$

in which C is the concentration, in  $\mu$ g per mL, of the pertinent USP Reference Standard in the Standard Preparation; AU is the corrected absorbance of the Assay Preparation; and AS is the corrected absorbance of the pertinent Standard Preparation. From the concentration of the Assay Preparation thus determined, and applying appropriate dilution factors,

calculate the percentage of sulfonamide in the specimen taken.

### 525 SULFUR DIOXIDE

The following methods are provided for the determination of sulfur dioxide in pharmaceutical excipients.

#### METHOD I

##### Procedure

Mix 20 g of the test specimen, accurately weighed, with 200 mL of an appropriate solvent as indicated in each individual monograph, and stir until a smooth suspension is obtained. Allow the test specimen mixture to remain undisturbed until most of the test specimen has settled, and filter the aqueous portion through paper (Whatman No. 1 or equivalent). To 100 mL of the clear filtrate add an additional solvent as indicated in each individual monograph, add 3 mL of starch TS, and titrate with 0.01 N iodine solution VS to the first permanent blue or purple color. Each 1.0 mL of 0.01 N iodine solution VS consumed corresponds to 0.003% of sulfur dioxide found.

#### METHOD II

##### Procedure

Transfer about 50 to 100 g of the substance to be tested, accurately weighed, to a 250-mL conical flask, add 100 to 150 mL of water, and mix. Cool to between 5° and 10°. While stirring with a magnetic stirrer, add 10 mL of cold 1.5 N sodium hydroxide (at a temperature between 5° and 10°). Stir for an additional 20 seconds, and add 10 mL of starch indicator solution, prepared as follows: mix 10 g of soluble starch with 50 mL of cold water, transfer to 1000 mL of boiling water, stir until completely dissolved, cool, and add 1 g of salicylic acid preservative. [note—Discard the solution after 1 month.] Add 10 mL of 2.0 N sulfuric acid (at a temperature between 5° and 10°), and titrate immediately with 0.005 N iodine VS until a light blue color persists for 1 minute (see [Titrimetry](#) 541). Perform a blank determination, using 200 mL of water treated similarly to the solution under test, and make any necessary correction. Each mL of 0.005 N iodine is equivalent to 0.16 mg of SO<sub>2</sub>.

#### METHOD III

##### Procedure

Dissolve 20.0 g of the test specimen in 150 mL of hot water in a flask having a round bottom and a long neck, add 5 mL of phosphoric acid and 1 g of sodium bicarbonate, and at once connect the flask to a condenser. [note—Excessive foaming can be alleviated by the addition of a few drops of a suitable antifoaming agent.] Distill 50 mL, receiving the distillate under the surface of 50 mL of 0.1 N iodine. Acidify the distillate with a few drops of hydrochloric acid, add 2 mL of [barium chloride TS](#), and heat on a steam bath until the liquid is nearly colorless. The precipitate of barium sulfate, if any, when filtered, washed, and ignited, weighs not more than 3 mg, corresponding to not more than 0.004% of sulfur dioxide, correction being made for any sulfate that may be present in 50 mL of the 0.1 N iodine.

Auxiliary Information— Please [check for your question in the FAQs](#) before contacting USP.

Pharmacopeial Forum: Volume No. 33(3) Page 498

### 531 THIAMINE ASSAY

[USP Reference Standards](#) 11 — [USP Thiamine Hydrochloride RS](#).

The following procedure is provided for the determination of thiamine as an ingredient of Pharmacopeial preparations containing other active constituents.

#### Special Solutions and Solvents—

POTASSIUM FERRICYANIDE SOLUTION— Dissolve 1.0 g of potassium ferricyanide in water to make 100 mL. Prepare fresh on the day of use.

OXIDIZING REAGENT— Mix 4.0 mL of Potassium Ferricyanide Solution with sufficient 3.5 N sodium hydroxide to make 100 mL. Use this solution within 4 hours.

QUININE SULFATE STOCK SOLUTION— Dissolve 10 mg of quinine sulfate in 0.1 N sulfuric acid to make 1000 mL. Preserve this solution, protected from light, in a refrigerator.

QUININE SULFATE STANDARD SOLUTION— Dilute 0.1 N sulfuric acid with Quinine Sulfate Stock Solution (39:1). This solution fluoresces to approximately the same degree as the thiochrome obtained from 1 µg of thiamine hydrochloride and is used to correct the fluorometer at frequent intervals for variation in sensitivity from reading to reading within an assay. Prepare this solution fresh on the day of use.

Standard Thiamine Hydrochloride Stock Solution— Transfer about 25 mg of [USP Thiamine Hydrochloride RS](#), accurately weighed, to a 1000-mL volumetric flask. Dissolve the weighed Standard in about 300 mL of dilute alcohol solution (1 in 5) adjusted with 3 N hydrochloric acid to a pH of 4.0, and add the acidified, dilute alcohol to volume. Store in a light-resistant container, in a refrigerator. Prepare this stock solution fresh each month.

Standard Preparation— Dilute a portion of Standard Thiamine Hydrochloride Stock Solution quantitatively and stepwise with 0.2 N hydrochloric acid to obtain the Standard Preparation, each mL of which represents 0.2 µg of [USP Thiamine Hydrochloride RS](#).

Assay Preparation— Place in a suitable volumetric flask sufficient amount of the material to be assayed, accurately weighed or measured by volume as directed, such that when diluted to volume with 0.2 N hydrochloric acid, the resulting solution will contain about 100 µg of thiamine hydrochloride (or mononitrate) per mL. If the sample is difficultly soluble, the solution may be heated on a steam bath, and then cooled and diluted with the acid to volume. Dilute 5 mL of this solution, quantitatively and stepwise, using 0.2 N hydrochloric acid, to an estimated concentration of 0.2 µg of thiamine hydrochloride (or mononitrate) per mL.

Procedure— Into each of three or more tubes (or other suitable vessels), of about 40-mL capacity, pipet 5 mL of Standard Preparation. To each of two of these tubes add rapidly (within 1 to 2 seconds), with mixing, 3.0 mL of Oxidizing Reagent, and within 30 seconds add 20.0 mL of isobutyl alcohol, then mix vigorously for 90 seconds by shaking the capped tubes manually, or by bubbling a stream of air through the mixture. Prepare a blank in the remaining tube of the standard by substituting for the Oxidizing Reagent an equal volume of 3.5 N sodium hydroxide and proceeding in the same manner.

Into each of three or more similar tubes pipet 5 mL of the Assay Preparation. Treat these tubes in the same manner as directed for the tubes containing the Standard Preparation.

Into each of the six tubes pipet 2 mL of dehydrated alcohol, swirl for a few seconds, allow the phases to separate, and decant or draw off about 10 mL of the clear, supernatant isobutyl alcohol solution into standardized cells, then measure the fluorescence in a suitable fluorometer, having an input filter of narrow transmittance range with a maximum at about 365 nm and an output filter of narrow transmittance range with a maximum at about 435 nm.

Calculation— The number of  $\mu$ g of C<sub>12</sub>H<sub>17</sub>CIN<sub>4</sub>OS-HCl in each 5 mL of the Assay Preparation is given by the formula:

$$(A - b) / (S - d)$$

in which A and S are the average fluorometer readings of the portions of the Assay Preparation and the Standard Preparation treated with Oxidizing Reagent, respectively, and b and d are the readings for the blanks of the Assay Preparation and the Standard Preparation, respectively.

Calculate the quantity, in mg, of thiamine hydrochloride (C<sub>12</sub>H<sub>17</sub>CIN<sub>4</sub>OS-HCl) in the assay material on the basis of the aliquots taken. Where indicated, the quantity, in mg, of thiamine mononitrate (C<sub>12</sub>H<sub>17</sub>N<sub>5</sub>O<sub>4</sub>S) may be calculated by multiplying the quantity of C<sub>12</sub>H<sub>17</sub>CIN<sub>4</sub>OS-HCl found by 0.9706.

541 TITRIMETRY

Direct Titrations— Direct titration is the treatment of a soluble substance, contained in solution in a suitable vessel (the titrate), with an appropriate standardized solution (the titrant), the endpoint being determined instrumentally or visually with the aid of a suitable indicator.

The titrant is added from a suitable buret and is so chosen, with respect to its strength (normality), that the volume added is between 30% and 100% of the rated capacity of the buret. [note—Where less than 10 mL of titrant is required, a suitable microburet is to be used.] The endpoint is approached directly but cautiously, and finally the titrant is added dropwise from the buret in order that the final drop added will not overrun the endpoint. The quantity of the substance being titrated may be calculated from the volume and the normality or molarity factor of the titrant and the equivalence factor for the substance given in the individual monograph.

Residual Titrations— Some Pharmacopeial assays require the addition of a measured volume of a volumetric solution, in excess of the amount actually needed to react with the substance being assayed, the excess of this solution then being titrated with a second volumetric solution. This constitutes a residual titration and is known also as a "back titration."

The quantity of the substance being titrated may be calculated from the difference between the volume of the volumetric solution originally added, corrected by means of a blank titration, and that consumed by the titrant in the back titration, due allowance being made for the respective normality or molarity factors of the two solutions, and the equivalence factor for the substance given in the individual monograph.

Complexometric Titrations— Successful complexometric titrations depend on several factors. The equilibrium constant for formation of the titrant-analyte complex must be sufficiently large that, at the endpoint, very close to 100% of the analyte has been complexed. The final complex must be formed rapidly enough that the analysis time is practical. When the analytical reaction is not rapid, a residual titration may sometimes be successful.

In general, complexometric indicators are themselves complexing agents. The reaction between metal ion and indicator must be rapid and reversible. The equilibrium constant for formation of the metal-indicator complex should be large enough to produce a sharp color change but must be less than that for the metal-titrant complex. Indicator choice is also restricted by the pH range within which the complexation reaction must be carried out and by interference of other ions arising from the sample or the buffer. Interfering ions may often be masked or "screened" via addition of another complexing agent. (The masking technique is also applicable to redox titrations.)

Oxidation-Reduction (Redox) Titrations— Determinations may often be carried out conveniently by the use of a reagent that brings about oxidation or reduction of the analyte. Many redox titration curves are not symmetric about the equivalence point, and thus graphical determination of the endpoint is not possible; but indicators are available for many determinations, and a redox reagent can often serve as its own indicator. As in any type of titration, the ideal indicator changes color at an endpoint that is as close as possible to the equivalence point. Accordingly, when the titrant serves as its own indicator, the difference between the endpoint and the equivalence point is determined only by the analyst's ability to detect the color change. A common example is the use of permanganate ion as an oxidizing titrant since a slight excess can easily be detected by its pink color. Other titrants that may serve as their own indicators are iodine, cerium (IV) salts, and potassium dichromate. In most cases, however, the use of an appropriate redox indicator will yield a much sharper endpoint.

It may be necessary to adjust the oxidation state of the analyte prior to titration through use of an appropriate oxidizing or reducing agent; the excess reagent must then be removed, e.g., through precipitation. This is nearly always the practice in the determination of oxidizing agents since most volumetric solutions of reducing agents are slowly oxidized by atmospheric oxygen.

Titrations in Nonaqueous Solvents— Acids and bases have long been defined as substances that furnish, when dissolved in water, hydrogen and hydroxyl ions, respectively. This definition, introduced by Arrhenius, fails to recognize the fact that properties characteristic of acids or bases may be developed also in other solvents. A more generalized definition is that of Brönsted, who defined an acid as a substance that furnishes protons, and a base as a substance that combines with protons. Even broader is the definition of Lewis, who defined an acid as any material that will accept an electron pair, a base as any material that will donate an electron pair, and neutralization as the formation of a coordination bond between an acid and a base.

The apparent strength of an acid or a base is determined by the extent of its reaction with a solvent. In water solution all strong acids appear equally strong because they react with the solvent to undergo almost complete conversion to oxonium ion and the acid anion (leveling effect). In a weakly protophilic solvent such as acetic acid the extent of formation of the acetate acidum ion shows that the order of decreasing strength for acids is perchloric, hydrobromic, sulfuric, hydrochloric, and nitric (differentiating effect).

Acetic acid reacts incompletely with water to form oxonium ion and is, therefore, a weak acid. In contrast, it dissolves in a base such as ethylenediamine, and reacts so completely with the solvent that it behaves as a strong acid. The same holds for perchloric acid.

This leveling effect is observed also for bases. In sulfuric acid almost all bases appear to be of the same strength. As the acid properties of the solvent decrease in the series sulfuric acid, acetic acid, phenol, water, pyridine, and butylamine, the bases become progressively weaker until all but the strongest have lost their basic properties. In order of decreasing

strength, the strong bases are sodium 2-aminoethoxide, potassium methoxide, sodium methoxide, and lithium methoxide.

Many water-insoluble compounds acquire enhanced acidic or basic properties when dissolved in organic solvents. Thus the choice of the appropriate solvent permits the determination of a variety of such materials by nonaqueous titration. Furthermore, depending upon which part of a compound is the physiologically active moiety, it is often possible to titrate that part by proper selection of solvent and titrant. Pure compounds can be titrated directly, but it is often necessary to isolate the active ingredient in pharmaceutical preparations from interfering excipients and carriers.

The types of compounds that may be titrated as acids include acid halides, acid anhydrides, carboxylic acids, amino acids, enols such as barbiturates and xanthines, imides, phenols, pyrroles, and sulfonamides. The types of compounds that may be titrated as bases include amines, nitrogen-containing heterocyclic compounds, oxazolines, quaternary ammonium compounds, alkali salts of organic acids, alkali salts of weak inorganic acids, and some salts of amines. Many salts of halogen acids may be titrated in acetic acid or acetic anhydride after the addition of mercuric acetate, which removes halide ion as the unionized mercuric halide complex and introduces the acetate ion.

For the titration of a basic compound, a volumetric solution of perchloric acid in glacial acetic acid is preferred, although perchloric acid in dioxane is used in special cases. The calomel-glass electrode system is useful in this case. In acetic acid solvent, this electrode system functions as predicted by theory.

For the titration of an acidic compound, two classes of titrant are available: the alkali metal alkoxides and the tetraalkylammonium hydroxides. A volumetric solution of sodium methoxide in a mixture of methanol and toluene is used frequently, although lithium methoxide in methanol-benzene solvent is used for those compounds yielding a gelatinous precipitate on titration with sodium methoxide.

The alkali error limits the use of the glass electrode as an indicating electrode in conjunction with alkali metal alkoxide titrants, particularly in basic solvents. Thus, the antimony-indicating electrode, though somewhat erratic, is used in such titrations. The use of quaternary ammonium hydroxide compounds, e.g., tetra-n-butylammonium hydroxide and trimethylhexadecylammonium hydroxide (in benzene-methanol or isopropyl alcohol), has two advantages over the other titrants in that (a) the tetraalkylammonium salt of the titrated acid is soluble in the titration medium, and (b) the convenient and well-behaved calomel-glass electrode pair may be used to conduct potentiometric titrations.

Because of interference by carbon dioxide, solvents for acidic compounds need to be protected from excessive exposure to the atmosphere by a suitable cover or by an inert atmosphere during the titration. Absorption of carbon dioxide may be determined by performing a blank titration. The blank should not exceed 0.01 mL of 0.1 N sodium methoxide VS per mL of solvent.

The endpoint may be determined visually by color change, or potentiometrically, as indicated in the individual monograph. If the calomel reference electrode is used, it is advantageous to replace the aqueous potassium chloride salt bridge with 0.1 N lithium perchlorate in glacial acetic acid for titrations in acidic solvents or potassium chloride in methanol for titrations in basic solvents.

Where these or other mixtures are specified in individual monographs, the calomel reference electrode is modified by first removing the aqueous potassium chloride solution and residual potassium chloride, if any, by rinsing with water, then eliminating residual water by rinsing with the required nonaqueous solvent, and finally filling the electrode with the designated nonaqueous mixture.

In nearly all cases, except those where silver ion might interfere, a silver-silver chloride reference electrode may be substituted for the calomel electrode. The silver-silver chloride electrode is more rugged, and its use helps to eliminate toxic mercury salts from the laboratory. Generally, a salt bridge may be used to circumvent interference by silver ion.

The more useful systems for titration in nonaqueous solvents are listed in [Table 1](#).

Table 1. Systems for Nonaqueous Titrations

Type of Solvent	Acidic (for titration of bases and their salts)	Relatively Neutral (for differential titration of bases)	Basic (for titration of acids)	Relatively Neutral (for differential titration of acids)
Solvent <sup>1</sup>	Glacial Acetic Acid	Acetonitrile	Dimethylformamide	Acetone
	Acetic Anhydride	Alcohols	n-Butylamine	Acetonitrile
	Formic Acid	Chloroform	Pyridine	Methyl Ethyl Ketone
	Propionic Acid	Benzene	Ethylenediamine	Methyl Isobutyl Ketone
	Sulfuryl Chloride	Toluene	Morpholine	tert-Butyl Alcohol
		Chlorobenzene		
		Ethyl Acetate		
		Dioxane		
Indicator	Crystal Violet	Methyl Red	Thymol Blue	Azo Violet
	Quinaldine Red	Methyl Orange	Thymolphthalein	Bromothymol Blue
	p-Naphtholbenzein	p-Naphtholbenzein	Azo Violet	p-Hydroxyazobenzene
	Alphezurine 2-G		o-Nitroaniline	Thymol Blue
	Malachite Green		p-Hydroxyazobenzene	
Electrodes	Glass-calomel	Glass-calomel	Antimony-calomel	Antimony-calomel
	Glass-silver-silver chloride	Calomel-silver-silver chloride	Antimony-glass	Glass-calomel
	Mercury-mercuric acetate		Antimony-antimony <sup>2</sup>	Glass-platinum <sup>2</sup>
			Platinum-calomel	
			Glass-calomel	

1 Relatively neutral solvents of low dielectric constant such as benzene, toluene, chloroform, or dioxane may be used in conjunction with any acidic or basic solvent in order to increase the sensitivity of the titration end-points.

2 In titrant.

**Indicator and Potentiometric Endpoint Detection**— The simplest and most convenient method by which the equivalence point, i.e., the point at which the stoichiometric analytical reaction is complete, may be determined is with the use of indicators. These chemical substances, usually colored, respond to changes in solution conditions before and after the equivalence point by exhibiting color changes that may be taken visually as the endpoint, a reliable estimate of the equivalence point.

A useful method of endpoint determination results from the use of electrochemical measurements. If an indicator electrode, sensitive to the concentration of the species undergoing titrimetric reaction, and a reference electrode, whose potential is insensitive to any dissolved species, are immersed in the titrate to form a galvanic cell, the potential difference between the electrodes may be sensed by a pH meter and used to follow the course of the reaction. Where such a series of measurements is plotted correctly (i.e., for an acid-base titration, pH versus mL of titrant added; for a precipimetric, complexometric, or oxidation-reduction titration, mV versus mL of titrant added), a sigmoid curve results with a rapidly changing portion (the "break") in the vicinity of the equivalence point. The midpoint of this linear vertical portion or the inflection point may be taken as the endpoint. The equivalence point may also be determined mathematically without plotting a curve. However, it should be noted that in asymmetric reactions, which are reactions in which the number of anions reacting is not the same as the number of cations reacting, the endpoint as defined by the inflection of the titration curve does not occur exactly at the stoichiometric equivalence point.

Thus, potentiometric endpoint detection by this method is not suitable in the case of asymmetric reactions, examples of which are the precipitation reaction,

and the oxidation-reduction reaction,

All acid-base reactions, however, are symmetrical. Thus, potentiometric endpoint detection may be employed in acid-base titrations and in other titrations involving symmetrical reversible reactions where an indicator is specified, unless otherwise directed in the individual monograph.

Two types of automatic electrometric titrators are available. The first is one that carries out titrant addition automatically and records the electrode potential differences during the course of titration as the expected sigmoid curve. In the second type, titrant addition is performed automatically until a preset potential or pH, representing the endpoint, is reached, at which point the titrant addition ceases.

Several acceptable electrode systems for potentiometric titrations are summarized in [Table 2](#).

Table 2. Potentiometric Titration Electrode Systems

Titration	Indicating Electrode	Equation <sup>1</sup>	Reference Electrode	Applicability <sup>2</sup>
Acid-base	Glass	$E = k + 0.0591 \text{ pH}$	Calomel or silver-silver chloride	Titration of acids and bases
Precipitometric (silver)	Silver	$E = E^\ominus + 0.0591 \log [\text{Ag}^+]$	Calomel (with potassium nitrate salt bridge)	Titration with or of silver involving halides or thiocyanate
Complexometric	Mercury-mercury(II)	$E = E^\ominus + 0.0296(\log k' - \text{pM})$	Calomel	Titration of various metals (M), e.g., $\text{Mg}^{2+}$ , $\text{Ca}^{2+}$ , $\text{Al}^{3+}$ , $\text{Bi}^{3+}$ , with EDTA
Oxidation-reduction	Platinum	$E = E^\ominus + (0.0591/n) \times \log \frac{[\text{ox}]}{[\text{red}]}$	Calomel or silver-silver chloride	Titrations with arsenite, bromine, cerate, dichromate, exacyanoferrate(III), iodate, nitrite, permanganate, thiosulfate

1 Appropriate form of Nernst equation describing the indicating electrode system: k = glass electrode constant;  $k'$  = constant derived from  $\text{Hg}-\text{Hg(II)}-\text{EDTA}$  equilibrium; M = any metal undergoing EDTA titration; [ox] and [red] from the equation,

2 Listing is representative but not exhaustive.

**Blank Corrections**— As previously noted, the endpoint determined in a titrimetric assay is an estimate of the reaction equivalence point. The validity of this estimate depends upon, among other factors, the nature of the titrate constituents and the concentration of the titrant. An appropriate blank correction is employed in titrimetric assays to enhance the reliability of the endpoint determination. Such a blank correction is usually obtained by means of a residual blank titration, wherein the required procedure is repeated in every detail except that the substance being assayed is omitted. In such instances, the actual volume of titrant equivalent to the substance being assayed is the difference between the volume consumed in the residual blank titration and that consumed in the titration with the substance present. The corrected volume so obtained is used in calculating the quantity of the substance being titrated, in the same manner as prescribed under **Residual Titrations**. Where potentiometric endpoint detection is employed, the blank correction is usually negligible.

### 551 ALPHA TOCOPHEROL ASSAY

The following procedure is provided for the determination of tocopherol as an ingredient.

**Hydrogenator**— A suitable device for low-pressure hydrogenation may be assembled as follows. Arrange in a rack or in clamps two conical centrifuge tubes, connected in series by means of glass and inert plastic tubing and suitable stoppers of glass, polymer, or cork (avoiding all use of rubber). Use one tube for the blank and the other for the assay specimen. Arrange a gas-dispersion tube so that the hydrogen issues as bubbles at the bottom of each tube. Pass the hydrogen first through the blank tube and then through the specimen tube.

**Procedure**— Pipet into a suitable vessel 25 mL of the final washed ether solution of the unsaponifiable fraction obtained as directed for **When Tocopherol Is Present** under [Procedure](#) in the [Vitamin A Assay](#) (571), and evaporate to about 5 mL. Without applying heat, remove the remaining ether in a stream of inert gas or by vacuum. Dissolve the residue in sufficient alcohol to give an expected concentration of about 0.15 mg of alpha tocopherol per mL. Pipet 15 mL into a 50-mL centrifuge tube, add about 200 mg of palladium catalyst, stir with a glass rod, and hydrogenate for 10 minutes in the Hydrogenator, using hydrogen that has been passed through alcohol in a blank tube. Add about 300 mg of chromatographic siliceous earth, stir with a glass rod, and immediately centrifuge until the solution is clear.

Test a 1-mL aliquot of the solution by removing the solvent by evaporation, dissolving the residue in 1 mL of chloroform, and adding 10 mL of [antimony trichloride TS](#): no detectable blue color appears. [note—If a blue color appears, repeat the hydrogenation for a longer time period, or with a new lot of catalyst.]

Pipet 2 mL of the supernatant into a glass-stoppered, opaque flask, add 1.0 mL of a 1 in 500 solution of ferric chloride in dehydrated alcohol,\* and begin timing the reaction, preferably with a stop watch. Add immediately 1.0 mL of a 1 in 200 solution of 2,2'-bipyridine in dehydrated alcohol, mix with swirling, add 21.0 mL of dehydrated alcohol, close the tube, and shake vigorously to ensure complete mixing. When about 9½ minutes have elapsed from the beginning of the reaction, transfer part of the mixture to one of a pair of matched 1-cm spectrophotometer cells. After 10 minutes, accurately timed, following the addition of the ferric chloride-dehydrated alcohol solution, determine the absorbance at 520 nm, with a suitable spectrophotometer, using dehydrated alcohol as the blank. Perform a blank determination with the same quantities of the same reagents and in the same manner, but using 2 mL of dehydrated alcohol in place of the 2 mL of the hydrogenated solution. Subtract the absorbance determined for the blank from that determined for the assay specimen, and designate the difference as AD.

Calculate the alpha tocopherol content, in mg, in the assay specimen taken by the formula:

$$30.2 \text{ AD} / (\text{LCD})$$

in which AD is the corrected absorbance; L is the length, in cm, of the absorption cell; and CD is the content of the assay specimen in the alcohol solution employed for the measurement of absorbance, expressed as g, capsules, or tablets per 100 mL.

\* note—The absorbance of the blank may be reduced, and the precision of the determination thereby improved, by purification of the dehydrated alcohol that is used throughout the assay. Purification may be accomplished by the addition of a few crystals (about 0.02%) of potassium permanganate and of a few pellets of potassium hydroxide to the dehydrated alcohol, and subsequent redistillation.

Auxiliary Information— Please [check for your question in the FAQs](#) before contacting USP.

## 561 ARTICLES OF BOTANICAL ORIGIN

## SAMPLING

In order to reduce the effect of sampling bias in qualitative and quantitative results, it is necessary to ensure that the composition of the sample used be representative of the batch of drugs being examined. The following sampling procedures are the minimum considered applicable to vegetable drugs. Some articles, or some tests, may require more rigorous procedures involving more containers being sampled or more samples per container.

## Gross Sample

Where external examination of containers, markings, and labels indicates that the batch can be considered to be homogeneous, take individual samples from the number of randomly selected containers indicated below. Where the batch cannot be considered to be homogeneous, divide it into sub-batches that are as homogeneous as possible, then sample each one as a homogeneous batch.

No. of Containers in Batch (N)	No. of Containers to be Sampled (n)
1 to 10	all
11 to 19	11
>19	$n = 10 + (N/10)$

(Round calculated "n" to next highest whole number.)

Samples are taken from the upper, middle, and lower sections of each container. If the crude material consists of component parts which are 1 cm or less in any dimension, and in the case of all powdered or ground materials, withdraw the sample by means of a sampling device that removes a core from the top to the bottom of the container, not less than two cores being taken in opposite directions. For materials with component parts over 1 cm in any dimension, withdraw samples by hand. In the case of large bales or packs, samples should be taken from a depth of 10 cm because the moisture content of the surface layer may be different from that of the inner layers.

Prepare the gross sample by combining and mixing the individual samples taken from each opened container, taking care not to increase the degree of fragmentation or significantly affect the moisture content.

## Laboratory Sample

Prepare the laboratory sample by repeated quartering of the gross sample.

note—Quartering consists of placing the sample, adequately mixed, as an even and square-shaped heap and dividing it diagonally into four equal parts. The two opposite parts are then taken and carefully mixed. The process is repeated as necessary until the required quantity is obtained.

The laboratory sample should be of a size sufficient for performing all the necessary tests.

## Test Sample

Unless otherwise directed in the individual monograph or test procedure below, prepare the test sample as follows:

Decrease the size of the laboratory sample by quartering, taking care that each withdrawn portion remains representative. In the case of unground or unpowdered drugs, grind the withdrawn sample so that it will pass through a No. 20 standard-mesh sieve, and mix the resulting powder well. If the material cannot be ground, reduce it to as fine a state as possible, mix by rolling it on paper or sampling cloth, spread it out in a thin layer and withdraw the portion for analysis.

## METHODS OF ANALYSIS

## Foreign Organic Matter

Test Sample— Unless otherwise specified in the individual monograph, weigh the following quantities of the laboratory sample, taking care that the withdrawn portion is representative (quartering if necessary):

Roots, rhizomes, bark, and herbs	500 g
Leaves, flowers, seeds, and fruit	250 g
Cut vegetable drugs (average weight of the pieces is less than 0.5 g)	50 g

Spread the sample out in a thin layer, and separate the foreign organic matter by hand as completely as possible. Weigh it, and determine the percentage of foreign organic matter in the weight of drug taken.

## Total Ash

Accurately weigh a quantity of the Test Sample, representing 2 to 4 g of the air-dried material, in a tared crucible, and incinerate, gently at first, and gradually increase the temperature to  $675 \pm 25^\circ$ , until free from carbon, and determine the weight of the ash. If a carbon-free ash cannot be obtained in this way, extract the charred mass with hot water, collect the insoluble residue on an ashless filter paper, incinerate the residue and filter paper until the ash is white or nearly so, then add the filtrate, evaporate it to dryness, and heat the whole to a temperature of  $675 \pm 25^\circ$ . If a carbon-free ash cannot be obtained in this way, cool the crucible, add 15 mL of alcohol, break up the ash with a glass rod, burn off the alcohol, and again heat the whole to a temperature of  $675 \pm 25^\circ$ . Cool in a desiccator, weigh the ash, and calculate the percentage of total ash from the weight of the drug taken.

## Acid-Insoluble Ash

Boil the ash obtained as directed under Total Ash, above, with 25 mL of 3 N hydrochloric acid for 5 minutes, collect the insoluble matter on a tared filtering crucible or ashless filter, wash with hot water, ignite, and weigh. Determine the percentage of acid-insoluble ash calculated from the weight of drug taken.

## Water-Soluble Ash

Boil the ash obtained as directed for Total Ash with 25 mL of water for 5 minutes. Collect the insoluble matter in a sintered-glass crucible or on an ashless filter paper. Wash with hot water, and ignite for 15 minutes at a temperature not exceeding  $450^\circ$ . Subtract the weight of this residue, in mg, obtained under Total Ash, and calculate the percentage of water-soluble ash with reference to the weight of sample as determined under Total Ash.

## Alcohol-Soluble Extractives

Method 1 (hot extraction method)— Transfer about 4 g of air-dried, coarsely powdered material, accurately weighed, to a glass-stoppered conical flask. Add 100 mL of alcohol, and weigh the flask. Shake, and allow to stand for 1 hour. Attach a reflux condenser to the flask, and boil gently for 1 hour, cool, and weigh. Readjust to the original weight with alcohol.

Shake, and filter rapidly through a dry filter. Transfer 25 mL of the filtrate to a tared flat-bottomed dish, and evaporate on a water bath to dryness. Dry at 105° for 6 hours, cool in a desiccator for 30 minutes, and weigh without delay. Calculate the content, in mg per g, of alcohol-extractable matter in the test specimen.

Method 2 (cold extraction method)— Transfer about 4 g of air-dried, coarsely powdered material, accurately weighed, to a glass-stoppered conical flask. Add 100 mL of alcohol, insert a stopper into the flask, and macerate for 24 hours, shaking frequently during the first 8 hours and then allowing to stand for 18 hours. Filter rapidly, taking precautions against loss of alcohol. Evaporate 25 mL of the filtrate to dryness in a tared, flat-bottomed, shallow dish, and dry at 105° to constant weight. Calculate the content, in mg per g, of alcohol-extractable matter in the test specimen.

#### Water-Soluble Extractives

Method 1 (hot extraction method)— Proceed as directed for Method 1 (hot extraction method) under Alcohol-soluble Extractives, except to use water in place of alcohol.

Method 2 (cold extraction method)— Proceed as directed for Method 2 (cold extraction method) under Alcohol-soluble Extractives, except to use water in place of alcohol.

#### Crude Fiber

Exhaust a weighed quantity of the Test Sample, representing about 2 g of the drug, with ether. Add 200 mL of boiling dilute sulfuric acid (1 in 78) to the ether-exhausted marc, in a 500-mL flask, and connect the flask to a reflux condenser. Reflux the mixture for 30 minutes, accurately timed, then filter through a linen or hardened-paper filter, and wash the residue on the filter with boiling water until the effluent washing is no longer acid. Rinse the residue back into the flask with 200 mL of boiling sodium hydroxide solution, adjusted to 1.25 percent by titration and free from sodium carbonate. Again reflux the mixture for 30 minutes, accurately timed, then rapidly filter through a tared filter, wash the residue with boiling water until the last washing is neutral, and dry it at 110° to constant weight. Incinerate the dried residue, ignite to constant weight, cool in a desiccator, and weigh the ash: the difference between the weight obtained by drying at 110° and that of the ash represents the weight of the crude fiber.

note—The boiling with acid and alkali should continue for 30 minutes, accurately timed, from the time that the liquid (which is cooled below the boiling point by being added to the cold flask) again boils. After the solution has been brought to boiling, the heat should be turned low enough just to maintain boiling. During the boiling, the flask should be gently rotated from time to time to wash down any particles that may adhere to the walls of the flask. A slow current of air introduced into the flask during the boiling operation aids in preventing excessive frothing.

#### Starch Content

Method 1— The following is a general procedure for all reducing sugars and may be used to determine the starch content in botanical articles.

Malt Extract— Use clean new barley malt of known efficacy, and grind just before use. Prepare malt extract just prior to use. For every 80 mL of malt extract needed, digest 5 g of ground malt with 100 mL of water at room temperature for 2 hours. [note—If an electric mixer is used, stir the mixture for 20 minutes.] Filter to obtain a clear extract, filtering again, if necessary, and mix the infusion well.

Test Solution— Extract about 5 g of the finely ground test specimen with five 10-mL portions of ether, using a filter that will completely retain the smallest starch granule. Allow the ether to evaporate from the residue, and wash with 250 mL of aqueous alcohol solution (10 in 100). Carefully wash the residue from the paper into a 500-mL beaker with about 100 mL of water. Heat to about 60° (avoiding, if possible, gelatinizing starch), and allow to stand for about 1 hour, stirring frequently to effect complete solution of sugars. Transfer to a wide-mouth bottle, rinse the beaker with a little warm water, and cool. Add an equal volume of alcohol, mix, and allow to stand for not less than 1 hour.

Centrifuge until the precipitate is closely packed on the bottom of the bottle, and decant the supernatant. Wash the precipitate with successive 50-mL portions of alcohol solution (50 in 100) by centrifuging and decanting through a suitable filter until the washings are sugar-free. [note—To test for the presence of sugar, transfer a few drops of the washings to a test tube, add 3 or 4 drops of a 20% solution of 1-naphthol in alcohol, prepared by dissolving 200 mg of 1-naphthol in 1 mL of alcohol and 2 mL of water. Shake the test tube well to allow uniform mixing, allow 2 to 4 mL of sulfuric acid to flow down the sides of the test tube, and hold the test tube upright. If sugar is present, the interface of the two liquids is colored faint to deep violet, and on shaking, the whole solution becomes blue-violet.]

Transfer the residue from the bottle and hardened filter to a beaker with about 50 mL of water. Immerse the beaker in boiling water, and stir constantly for 15 minutes or until all of the starch is gelatinized. Cool the beaker to 55°, add 20 mL of Malt Extract, and hold at this temperature for 1 hour. Heat again to boiling for a few minutes, cool to 55°, add 20 mL of Malt Extract, and hold at this temperature for 1 hour or until the residue when treated with [iodine TS](#) shows no blue tinge upon microscopic examination. Cool, dilute with water to 250 mL, and filter.

General Procedure— Transfer 200 mL of the Test Solution to a flask fitted with a reflux condenser, add 20 mL of hydrochloric acid, and heat in a boiling water bath for 2½ hours. Cool, nearly neutralize with [sodium hydroxide TS](#), complete neutralization with [sodium carbonate TS](#), dilute with water to 500 mL, mix, and filter. The volume of aliquot taken depends on the starch content of the specimen under test (see [Table 1](#)). The aliquot should contain between 100 and 200 mg of dextrose. Transfer 50 mL of the filtrate to a 400-mL alkali-resistant glass beaker, add 50 mL of alkaline cupric tartrate TS, cover the beaker with a water glass, and heat. Adjust the flame in the burner so that the contents of the flask begin to boil in 4 minutes and continue boiling for exactly 2 minutes. Filter the hot solution at once through a sintered-glass filter. Wash the precipitate of cuprous oxide thoroughly with water at about 60°, then with 10 mL of alcohol, and finally with 10 mL of ether.

Table 1. Determination of the Optimum Aliquot

% of Expected Starch Content	Aliquot in mL
60	25
50	35
40	50
30	50
20	50

For solutions of reducing sugars of comparatively high purity, proceed as directed under Method 1A to determine the amount of reduced copper obtained by weighing the dried cuprous oxide. For solutions of reducing sugars containing large amounts of organic impurities, including sucrose, proceed as directed under Method 1B to determine the amount of reduced copper obtained by titration with sodium thiosulfate.

method 1a— Dry the precipitate obtained under General Procedure for 30 minutes in an oven at 110 ± 2°, cool to room temperature in a desiccator, and weigh. Refer to [Table 2](#) to find the quantity of dextrose, in mg, corresponding to the weight of cuprous oxide found. Determine the percentage of dextrose and then the content of starch by the following formula:

$$\text{Percentage of dextrose} =$$

$$\frac{\text{wt. of dextrose in mg} \times 0.1 \times 500}{\text{wt. of sample in g} \times \text{aliquot in mL}}$$

$$\text{Content of starch} = \% \text{ dextrose} \times 0.9.$$

Table 2. Calculating Dextrose (Applicable when Cu<sub>2</sub>O is weighed directly) (Expressed in mg)

Cuprous Oxide (Cu <sub>2</sub> O)	Dextrose (d-Glucose)	Cuprous Oxide (Cu <sub>2</sub> O)	Dextrose (d-Glucose)	Cuprous Oxide (Cu <sub>2</sub> O)	Dextrose (d-Glucose)	Cuprous Oxide (Cu <sub>2</sub> O)	Dextrose (d-Glucose)	Cuprous Oxide (Cu <sub>2</sub> O)	Dextrose (d-Glucose)

## METHOD 1B—

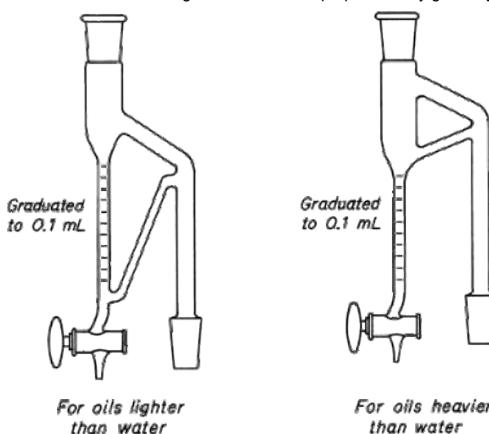

Sodium Thiosulfate Solution— Transfer 3.9 g of sodium thiosulfate, accurately weighed, to a 100-mL volumetric flask, dissolve in and dilute with water to volume, and mix.

Potassium Iodide Solution— Dissolve 42 g of potassium iodide in 100 mL of water.

Sodium Acetate Solution— Dissolve 5.74 g of sodium acetate in 10 mL of water.

Copper Solution— Transfer about 0.3 g of pure electrolytic copper, accurately weighed, to a 250-mL flask, add 5 mL of nitric acid to dissolve the copper, add about 25 mL of water, and boil to expel red fumes. Add about 5 mL of bromine TS, and boil until the bromine is completely removed. Cool, add 10 mL of Sodium Acetate Solution followed by 10 mL of Potassium Iodide Solution, and titrate with Sodium Thiosulfate Solution to a light yellow color. Add enough starch TS to produce a marked blue color, and continue the titration. As the endpoint

nears, add 2 g of potassium thiocyanate, and stir until completely dissolved. Continue titration until the precipitate is completely white. One mL of sodium thiosulfate solution is equivalent to about 10 mg of copper. [note—It is essential that the concentration of Potassium Iodide Solution be carefully regulated. If the solution contains less than 320 mg of copper at the completion of titration, add 4.2 to 5 g of potassium iodide to make a total solution of 100 mL. If greater amounts of Cu are present, add Potassium Iodide Solution slowly from buret with constant agitation in amounts proportionately greater.]

Traps for Volatile Oil Apparatus

Procedure— Wash the precipitated cuprous oxide obtained under General Procedure with water, cover this filter with a watch glass and dissolve the cuprous oxide with 5 mL of nitric acid directed under the watch glass with a pipet. Collect the filtrate in a 250-mL flask, wash the watch glass and the filter with water. Collect all the washings in the flask. Boil the contents of the flask to expel red fumes. Add about 5 mL of bromine TS, and boil until the bromine is completely removed. Cool, and proceed as directed under Copper Solution beginning with “add 10 mL of Sodium Acetate Solution.” From the volume of Sodium Thiosulfate Solution consumed, obtain the weight of copper, in mg, by multiplying by 1.1259 to obtain the weight, in mg, of cuprous oxide. From [Table 2](#), find the quantity of dextrose, in mg, corresponding to the weight of cuprous oxide. The content of starch is equivalent to the weight, in mg, of dextrose obtained times 0.9. Conduct a blank determination, using 50 mL of [alkaline cupric tartrate TS](#) and 50 mL of Malt Extract. If the weight of the cuprous oxide so obtained exceeds 0.5 mg, correct the result of the determination accordingly. [note—The alkaline cupric tartrate TS deteriorates on standing and the quantity of cuprous oxide obtained in the blank determination increases.]

Method 2— The following method is specific for dextrose (glucose), and because of its extreme sensitivity it may account for differences noted between values obtained from the same specimen. Duplicate determinations do not vary more than 2%.

Glucoamylase Solution— Prepare a solution of glucoamylase in water containing 30 International Units (IU) per mL. Use glucoamylase obtained preferably from *Rhizopus delemar*. The total glucoamylase activity of the test specimen being used should be not less than 150 IU.

Acetate Buffer Solution— Dissolve 16.4 g of sodium acetate in 100 mL of water, add 12.0 mL of glacial acetic acid, and mix. The pH of this solution is 4.8.

Phosphate Buffer— Dissolve 3.63 g of tris (hydroxymethyl) aminomethane and 5.0 g of monobasic sodium phosphate in 50.0 mL of water. At 37°, adjust with phosphoric acid to a pH of 7.0, dilute with water to 100.0 mL, and mix. [note—The pH of the buffer medium is sensitive to temperature and should be adjusted to the desired pH at the temperature to be used during incubation.]

Enzyme Solution— Dissolve 30 mg of glucose oxidase (Type II from *Aspergillus niger*), 3 mg of peroxidase (Type I from horseradish), and 10 mg of potassium ferrocyanide in 100 mL of Phosphate Buffer. [note—This mixture can be stored in a refrigerator for up to 10 days.]

18 N Sulfuric Acid— Add slowly, while stirring, 54 mL of sulfuric acid to 102 mL of water, allow to cool to 25°, and mix.

Standard Solutions— Dissolve an accurately weighed quantity of [USP Dextrose RS](#) in water to obtain a solution containing 1.0 mg of [USP Dextrose RS](#) per mL. Quantitatively dilute a known volume of this solution with water to obtain Standard Solutions A, B, C, D, and E, having known concentrations of 10, 20, 25, 40, and 50 µg per mL of [USP Dextrose RS](#), respectively. [note—Allow 4 hours for complete mutarotation before use.]

Test Solutions— Extract about 5 g of finely ground test specimen with five 25-mL portions of 80% alcohol, and filter. Remove all the alcohol from the residue by drying in an air oven at 105° for about 8 hours. [Note 1—Any traces of alcohol remaining in the residue will inhibit glucoamylase.] Cool, and transfer the flask containing the dried test specimen to a desiccator. Transfer about 1 g, accurately weighed, of the test specimen to a previously tared flask, add 25 mL of water, and adjust with phosphoric acid to a pH between 5.0 and 7.0, if necessary. Boil the suspension for about 3 minutes, transfer the flask to an autoclave, and heat to 135° for 2 hours. Remove the flask from the autoclave, maintain the temperature near 55°, and add 2.5 mL of Acetate Buffer Solution and sufficient water to adjust the total weight of the solution to 45 ± 1 g. Immerse the flask in a water bath maintained at 55 ± 1°, and add 5 mL of Glucoamylase Solution. Continuously swirl the flask for 2 hours to effect hydrolysis, filter through filter paper into a 250-mL volumetric flask, wash quantitatively with water, and collect all the washings in the flask. Dilute the contents of the flask with water to volume, and mix. Transfer 1 mL of an aliquot containing 20 to 60 µg of d-glucose to each of five test tubes. [Note 2—In order to obtain the range of concentration of glucose in the hydrolysate, quantitatively dilute, if necessary, with water to volume.] Add 2 mL of Enzyme Solution to each of the five test tubes, and place the test tubes in the dark at 37 ± 1° for exactly 30 minutes to develop the color. At the end of 30 minutes, add 2 mL of 18 N Sulfuric Acid to each of the test tubes to stop the reaction, and mix.

Control Solution— Transfer an accurately weighed quantity of about 0.4 g of starch to a previously tared flask and proceed as directed under Test Solutions beginning with “add 25 mL of water and, adjust the pH with phosphoric acid.”

Procedure— Concomitantly determine the absorbances of the Standard Solutions and the Test Solutions at the wavelength of maximum absorbance at about 540 nm, with a suitable spectrophotometer, using the Control Solution as the blank to set the instrument. Plot the absorbance values of the Standard Solutions versus concentration, in µg per mL, of dextrose, and draw the straight line best fitting the five plotted points. From the graph so obtained, determine the concentration, C, in µg per mL, of dextrose in each of the Test Solutions, calculate the average concentration, in µg per mL, of the solution under test. The percentage of starch content in the weight of the test specimen taken by the equation is calculated by the formula:

$$(0.9C / 106)(V1)(250 / V0)(100 / E)(100 / W) = 2.25CV1 / V0EW$$

in which E is the weight, in g, of the test specimen taken; V0 is the volume, in mL, of the aliquot taken from the 250-mL volumetric flask; W is the percentage of dry weight of the test specimen; and V1 is the volume, in mL, if extra dilution is done (see Note 2 under Test Solutions). [note—V0 is 1.0 when no extra dilution is done.]

#### Volatile Oil Determination

Set up a round-bottom, shortneck, 1-liter flask in a heating mantle set over a magnetic stirrer. Insert an egg-shaped stirring bar magnet in the flask, and attach a cold-finger condenser and an appropriate volatile oil trap of the type illustrated.

Coarsely comminute a sufficient quantity of the drug to yield from 1 to 3 mL of volatile oil. Small seeds, fruits, or broken leaves of herbs ordinarily do not need comminution. Very fine powders are to be avoided. If this is not possible, it may be necessary to mix them with purified sawdust or purified sand. Place a suitable quantity of the drug, accurately weighed, in the flask, and fill it one-half with water. Attach the condenser and the proper separator. Boil the contents of the flask, using a suitable amount of heat to maintain gentle boiling for 2 hours, or until the volatile oil has been completely separated from the drug and no longer collects in the graduated tube of the separator.

If a proper quantity of the volatile oil has been obtained in the graduated tube of the separator, it can be read to tenths of 1 mL, and the volume of volatile oil from each 100 g of drug can be calculated from the weight of the drug taken. The graduations on the separator “for oils heavier than water” are so placed that oil remains below the aqueous condensate that automatically flows back into the flask.

#### Water Content

For unground or unpowdered drugs, prepare about 10 g of the Laboratory Sample by cutting, granulating, or shredding, so that the parts are about 3 mm in thickness. Seeds or fruits smaller than 3 mm should be cracked. Avoid the use of high-speed mills in preparing the sample, and exercise care that no appreciable amount of moisture is lost during the preparation and that the portion taken is representative of the Laboratory Sample. Determine the water content as directed for Procedure for Articles of Botanical Origin in the [Method III \(Gravimetric\) under Water Determination](#) (921).

#### TEST FOR AFLATOXINS

Caution—Aflatoxins are highly dangerous, and extreme care should be exercised in handling aflatoxin materials.

This test is provided to detect the possible presence of aflatoxins B1, B2, G1, and G2 in any material of plant origin. Unless otherwise specified in the individual monograph, use the following method.

Zinc Acetate-Aluminum Chloride Reagent— Dissolve 20 g of zinc acetate and 5 g of aluminum chloride in sufficient water to make 100 mL.

Sodium Chloride Solution— Dissolve 5 g of sodium chloride in 50 mL of water.

Test Solution 1— Grind about 200 g of plant material to a fine powder. Transfer about 50 g of the powdered material, accurately weighed, to a glass-stoppered flask. Add 200 mL of a mixture of methanol and water (17:3). Shake vigorously by mechanical means for not less than 30 minutes, and filter. [note—If the solution has interfering plant pigments, proceed as directed for Test Solution 2.] Discard the first 50 mL of the filtrate, and collect the next 40-mL portion. Transfer the filtrate to a separatory funnel. Add 40 mL of Sodium Chloride Solution and 25 mL of solvent hexane, and shake for 1 minute. Allow the layers to separate, and transfer the lower aqueous layer to a second separatory funnel. Extract the aqueous layer in the separatory funnel twice, each time with 25 mL of methylene chloride, by shaking for 1 minute. Allow the layers to separate each time, separate the lower organic layer, and

Collect the combined organic layers in a 125-mL conical flask. Evaporate the organic solvent to dryness on a water bath. Cool the residue. If interferences exist in the residue, proceed as directed for Cleanup Procedure; otherwise, dissolve the residue obtained above in 0.2 mL of a mixture of chloroform and acetonitrile (9.8:0.2), and shake by mechanical means if necessary.

Test Solution 2— Collect 100 mL of the filtrate from the start of the flow, and transfer to a 250-mL beaker. Add 20 mL of Zinc Acetate-Aluminum Chloride Reagent and 80 mL of water. Stir, and allow to stand for 5 minutes. Add 5 g of a suitable filtering aid, such as diatomaceous earth, mix, and filter. Discard the first 50 mL of the filtrate, and collect the next 80-mL portion. Proceed as directed for Test Solution 1, beginning with “Transfer the filtrate to a separatory funnel.”

Cleanup Procedure— Place a medium-porosity sintered-glass disk or a glass wool plug at the bottom of a 10-mm × 300-mm chromatographic tube. Prepare a slurry of 2 g of silica gel with a mixture of ethyl ether and solvent hexane (3:1), pour the slurry into the column, and wash with 5 mL of the same solvent mixture. Allow the absorbent to settle, and add to the top of the column a layer of 1.5 g of anhydrous sodium sulfate. Dissolve the residue obtained above in 3 mL of methylene chloride, and transfer it to the column. Rinse the flask twice with 1-mL portions of methylene chloride, transfer the rinses to the column, and elute at a rate not greater than 1 mL per minute. Add successively to the column 3 mL of solvent hexane, 3 mL of ethyl ether, and 3 mL of methylene chloride; elute at a rate not greater than 3 mL per minute; and discard the eluates. Add to the column 6 mL of a mixture of methylene chloride and acetone (9:1), and elute at a rate not greater than 1 mL per minute, preferably without the aid of vacuum. Collect this eluate in a small vial, add a boiling chip if necessary, and evaporate to dryness on a water bath. Dissolve the residue in 0.2 mL of a mixture of chloroform and acetonitrile (9.8:0.2), and shake by mechanical means if necessary.

Aflatoxin Solution— [Caution—Aflatoxins are highly toxic. Handle with care.] Dissolve accurately weighed quantities of aflatoxin B1, aflatoxin B2, aflatoxin G1, and aflatoxin G2 in a mixture of chloroform and acetonitrile (9.8:0.2) to obtain a solution having concentrations of 0.5 µg per mL each of aflatoxin B1 and aflatoxin G1, and 0.1 µg per mL each of aflatoxin B2 and aflatoxin G2.

Procedure— Separately apply 2.5 µL, 5 µL, 7.5 µL, and 10 µL of the Aflatoxin Solution and three 10-µL applications of either Test Solution 1 or Test Solution 2 to a suitable thin-layer chromatographic plate (see [Chromatography \(621\)](#)) coated with a 0.25-mm layer of chromatographic silica gel mixture. Superimpose 5 µL of the Aflatoxin Solution on one of the three 10-µL applications of the Test Solution. Allow the spots to dry, and develop the chromatogram in an unsaturated chamber containing a solvent system consisting of a mixture of chloroform, acetone, and isopropyl alcohol (85:10:5) until the solvent front has moved not less than 15 cm from the origin. Remove the plate from the developing chamber, mark the solvent front, and allow the plate to air-dry. Locate the spots on the plate by examination under UV light at 365 nm: the four applications of the Aflatoxin Solution appear as four clearly separated blue fluorescent spots; the spot obtained from the Test Solution that was superimposed on the Aflatoxin Solution is no more intense than that of the corresponding Aflatoxin Solution; and no spot from any of the other Test Solutions corresponds to any of the spots obtained from the applications of the Aflatoxin Solution. If any spot of aflatoxins is obtained in the Test Solution, match the position of each fluorescent spot of the Test Solution with those of the Aflatoxin Solution to identify the type of aflatoxin present. The intensity of the aflatoxin spot, if present in the Test Solution, when compared with that of the corresponding aflatoxin in the Aflatoxin Solution will give an approximate concentration of aflatoxin in the Test Solution.

#### GENERAL METHOD FOR PESTICIDE RESIDUES ANALYSIS

Definition— Where used in this Pharmacopeia, the designation pesticide applies to any substance or mixture of substances intended to prevent, destroy, or control any unwanted species of plants or animals causing harm during or otherwise interfering with the production, processing, storage, transport, or marketing of pure articles. The designation includes substances intended for use as growth regulators, defoliants, or desiccants, and any substance applied to crops before or after harvest to protect the product from deterioration during storage and transport.

Limits— Within the United States, many botanicals are treated as dietary supplements and are subject to the statutory provisions of the Federal Food, Drug, and Cosmetic Act that governs foods but not drugs. Limits for pesticides for foods are determined by the Environmental Protection Agency (EPA), and where no limit is set, the limit is zero. The limits contained herein, therefore, are not applicable in the United States when articles of botanical origins are labeled for food purposes. The limits, however, may be applicable in other countries where the presence of pesticide residues is permitted. Unless otherwise specified in the individual monograph, the article under test contains not more than the amount of any pesticide indicated in [Table 3](#). The limits applying to pesticides not listed in [Table 3](#) and whose presence is suspected for any reason comply with the regulations of the EPA.

Where a pesticide is not listed in [Table 3](#) or in EPA regulations, calculate the limit by the formula:

$$AM / 100B$$

in which A is the acceptable daily intake (ADI), in mg per kg of body weight; M is the body weight, in kg; and B is the daily dose of the article, in kg.

Table 3

Substance	Limit (mg/kg)
Alachlor	0.02
Aldrin and Dieldrin (sum of)	0.05
Azinphos-methyl	1.0
Bromopropylate	3.0
Chlordane (sum of cis- and trans- isomers and oxychlordane)	0.05
Chlorfenvinphos	0.5
Chlorpyrifos	0.2
Chlorpyrifos-methyl	0.1
Cypermethrin (and isomers)	1.0
DDT (sum of p,p'-DDT, o,p'-DDT, p,p'-DDE, and p,p'-TDE)	1.0
Deltamethrin	0.5
Diazinon	0.5
Dichlorvos	1.0
Dithiocarbamates (as CS <sub>2</sub> )	2.0
Endosulfan (sum of endosulfan isomers and endosulfan sulfate)	3.0
Endrin	0.05
Ethion	2.0
Fenitrothion	0.5
Fenvalerate	1.5
Fonofos	0.05
Heptachlor (sum of heptachlor and heptachlor epoxide)	0.05
Hexachlorobenzene	0.1
Hexachlorocyclohexane isomers (other than γ)	0.3

Lindane ( $\gamma$ -hexachlorocyclohexane)	0.6
Malathion	1.0
Methidathion	0.2
Parathion	0.5
Parathion-methyl	0.2
Permethrin	1.0
Phosalone	0.1
Piperonyl butoxide	3.0
Pirimiphos-methyl	4.0
Pyrethrins (sum of)	3.0
Quintozene (sum of quintozene, pentachloroaniline and methyl pentachlorophenyl sulfide)	1.0

If the article is intended for the preparation of extracts, tinctures, or other pharmaceutical forms whose preparation method modifies the content of pesticides in the finished product, calculate the limits by the formula:

AME / 100B

in which E is the extraction factor of the preparation method, determined experimentally; and A, M, and B are as defined above.

**Sampling—**

Method— For articles in containers holding less than 1 kg, mix the contents, and withdraw a quantity sufficient for the tests. For articles in containers holding between 1 and 5 kg, withdraw equal portions from the upper, middle, and lower parts of the container, each of the samples being sufficient to carry out the tests. Thoroughly mix the samples, and withdraw an amount sufficient to carry out the tests. For containers holding more than 5 kg, withdraw three samples, each weighing not less than 250 g, from the upper, middle, and lower parts of the container. Thoroughly mix the samples, and withdraw a portion sufficient to carry out the tests.

Size of Sampling— If the number of containers, n, is three or fewer, withdraw samples from each container as indicated above. If the number of containers is more than three, take samples from

$$\sqrt{n} + 1$$

containers, rounding up to the nearest whole number if necessary.

note—Conduct tests without delay to avoid possible degradation of the residues. If this is not possible, store the samples in hermetic containers suitable for food contact, at a temperature below 0°, and protected from light.

Reagents— Use reagents and solvents that are free from any contaminants, especially pesticides, that might interfere with the analysis. It is often necessary to use special grade solvents suitable for pesticide residue analysis or solvents that have recently been redistilled in an apparatus made entirely of glass. In any case, suitable blank tests must be performed.

Preparation of Apparatus— Clean all equipment, especially glassware, to ensure that it is free from pesticides. Soak all glassware for a minimum of 16 hours in a solution of phosphate-free detergent, rinse with copious quantities of distilled water, and then wash with acetone, followed by hexane or heptane.

Qualitative and Quantitative Analysis of Pesticide Residues— Use validated analytical procedures that satisfy the following criteria. The method, especially with respect to its purification steps, is suitable for the combination of pesticide residue and substance under test, and is not susceptible to interference from co-extractives. Measure the limits of detection and quantification for each pesticide matrix combination to be analyzed: the method is shown to recover between 70% and 110% of each pesticide; the repeatability and reproducibility of the method are not less than the appropriate values indicated in [Table 4](#); and the concentrations of test and reference solutions and the setting of the apparatus are such that a linear response is obtained from the analytical detector.

Table 4

Concentration of the Pesticide (mg/kg)	Repeatability (difference, $\pm$ mg/kg)	Reproducibility (difference, $\pm$ mg/kg)
0.010	0.005	0.01
0.100	0.025	0.05
1.000	0.125	0.25

**TEST FOR PESTICIDES**

Unless otherwise specified in the individual monograph, the following methods may be used for the analysis of pesticides. Depending on the substance being examined, it may be necessary to modify, sometimes extensively, the procedure described hereafter. Additionally, it may be necessary to perform another method with another column having a different polarity, another detection method (e.g., mass spectrometry), or a different method (e.g., immunochemical method) to confirm the results.

Extraction— [note—Use the following procedure for the analysis of samples of articles having a water content of less than 15%. Samples having a higher water content may be dried, provided that the drying procedure does not significantly affect the pesticide content.] To 10 g of the coarsely powdered substance under test, add 100 mL of acetone, and allow to stand for 20 minutes. Add 1 mL of a solution in toluene containing 1.8 g of carbophenothion per mL. Mix in a high-speed blender for 3 minutes. Filter this solution, and wash the residue with two 25-mL portions of acetone. Combine the filtrate and the washings, and heat, in a rotary evaporator, maintaining the temperature of the bath below 40° until the solvent has almost completely evaporated. To the residue add a few mL of toluene, and heat again until the acetone is completely removed. Dissolve the residue in 8 mL of toluene. Pass through a membrane filter having a 45- $\mu$ m porosity, rinse the flask and the filter with toluene, dilute with toluene to 10.0 mL (Solution A), and mix.

**Purification—**

Organochlorine, Organophosphorus, and Pyrethroid Insecticides— The size-exclusion chromatograph is equipped with a 7.8-mm  $\times$  30-cm stainless steel column containing 5- $\mu$ m packing L21. Toluene is used as the mobile phase at a flow rate of about 1 mL per minute.

Performance of the Column— Inject 100  $\mu$ L of a solution in toluene containing, in each mL, 0.5 mg of methyl red and 0.5 mg of oracet blue. The column is not suitable unless the color

the eluate changes from orange to blue at an elution volume of about 10.3 mL. If necessary, calibrate the column, using a solution in toluene containing suitable concentrations of the pesticide of interest having the lowest molecular weight (for example, dichlorvos) and that having the highest molecular weight (for example, deltamethrin). Determine which fraction of the eluate contains both pesticides.

Purification of the Test Solution— Inject a suitable volume (100 to 500  $\mu$ L) of Solution A into the chromatograph. Collect the fraction (Solution B) as determined above under Performance of the Column. Organophosphorus pesticides elute between 8.8 and 10.9 mL. Organochlorine and pyrethroid pesticides elute between 8.5 and 10.3 mL.

Organochlorine and Pyrethroid Insecticides— Into a 5-mm  $\times$  10-cm chromatographic column, introduce a piece of fat-free cotton and 0.5 g of silica gel treated as follows. Heat chromatographic silica gel in an oven at 150° for at least 4 hours. Allow to cool, and add dropwise a quantity of water corresponding to 1.5% of the weight of silica gel used. Shake vigorously until agglomerates have disappeared, and continue shaking by mechanical means for 2 hours. Condition the column with 1.5 mL of hexane. [note—Prepacked columns containing about 0.50 g of a suitable silica gel may also be used, provided they have been previously validated.] Concentrate Solution B almost to dryness, with the aid of a stream of helium or oxygen-free nitrogen, and dilute with toluene to a suitable volume (200  $\mu$ L to 1 mL, according to the volume injected in the preparation of Solution B). Quantitatively transfer this solution to the column, and proceed with the chromatography, using 1.8 mL of toluene as the mobile phase. Collect the eluate (Solution C).

#### Quantitative Analysis of Organophosphorus Insecticides—

Test Solution— Concentrate Solution B almost to dryness, with the aid of a stream of helium, dilute with toluene to 100  $\mu$ L, and mix.

Standard Solution— Prepare at least three solutions in toluene containing each of the pesticides of interest and carbophenothion at concentrations suitable for plotting a calibration curve.

Chromatographic System— The gas chromatograph is equipped with an alkali flame-ionization detector or a flame-photometric detector and a 0.32-mm  $\times$  30-m fused silica column coated with a 0.25- $\mu$ m layer of phase G1. Hydrogen is used as the carrier gas. Other gases, such as helium or nitrogen, may also be used. The injection port temperature is maintained at 250°, and the detector is maintained at 275°. The column temperature is maintained at 80° for 1 minute, then increased to 150° at a rate of 30° per minute, maintained at 150° for 3 minutes, then increased to 280° at a rate of 4° per minute, and maintained at this temperature for 1 minute. Use carbophenothion as the internal standard. [Note—If necessary, use a second internal standard to identify any possible interference with the peak corresponding to carbophenothion.] Inject the chosen volume of each solution, record the chromatograms, and measure the peak responses: the relative retention times are approximately those listed in [Table 5](#). Calculate the content of each pesticide from the peak areas and the concentrations of the solution.

Table 5

Substance	Relative Retention Time
Dichlorvos	0.20
Fonofos	0.50
Diazinon	0.52
Parathion-methyl	0.59
Chlorpyrifos-methyl	0.60
Pirimiphos-methyl	0.66
Malathion	0.67
Parathion	0.69
Chlorpyrifos	0.70
Methidathion	0.78
Ethion	0.96
Carbophenothion	1.00
Azinphos-methyl	1.17
Phosalone	1.18

#### Quantitative Analysis of Organochlorine and Pyrethroid Insecticides—

Test Solution— Concentrate Solution C almost to dryness, with the aid of a stream of helium or oxygen-free nitrogen, dilute with toluene to 500  $\mu$ L, and mix.

Standard Solution— Prepare at least three solutions in toluene containing each of the pesticides of interest and carbophenothion at concentrations suitable for plotting a calibration curve.

Chromatographic System— The gas chromatograph is equipped with an electron-capture detector, a device allowing direct on-column cold injection, and a 0.32-mm  $\times$  30-m fused silica column coated with a 0.25- $\mu$ m layer of phase G1. Hydrogen is used as the carrier gas. Other gases, such as helium or nitrogen, may also be used. The injection port temperature is maintained at 275°, and the detector is maintained at 300°. The column temperature is maintained at 80° for 1 minute, then increased to 150° at a rate of 30° per minute, maintained at 150° for 3 minutes, then increased to 280° at a rate of 4° per minute, and maintained at this temperature for 1 minute. Use carbophenothion as the internal standard. [note—If necessary, use a second internal standard to identify any possible interference with the peak corresponding to carbophenothion.] Inject the chosen volume of each solution, record the chromatograms, and measure the peak responses: the relative retention times are approximately those listed in [Table 6](#). Calculate the content of each pesticide from the peak areas and the concentrations of the solutions.

Table 6

Substance	Relative Retention Time
$\alpha$ -Hexachlorocyclohexane	0.44
Hexachlorobenzene	0.45
$\beta$ -Hexachlorocyclohexane	0.49
Lindane	0.49
$\delta$ -Hexachlorocyclohexane	0.54
$\epsilon$ -Hexachlorocyclohexane	0.56
Heptachlor	0.61
Aldrin	0.68
cis-Heptachlor epoxide	0.76
o, p'-DDE	0.81
$\alpha$ -Endosulfan	0.82
Dieldrin	0.87
p, p'-DDE	0.87
o, p'-DDD	0.89
Endrin	0.91

B-Endosulfan	0.92
o, p'-DDT	0.95
Carbophenothion	1.00
p, p'-DDT	1.02
cis-Permethrin	1.29
trans-Permethrin	1.31
Cypermethrin*	1.40
Fenvalerate*	1.47
	1.49
Deltamethrin	1.54

\* The substance shows several peaks.

#### 563 IDENTIFICATION OF ARTICLES OF BOTANICAL ORIGIN

Identification of raw plant material intended for use in the manufacture of pharmaceuticals, excipients, or dietary supplements is carried out by examining the morphological and histological features of the article under test and by performing diagnostic chemical tests on the article. The botanical and chemical characteristics of the test article are then compared to the known botanical and chemical characteristics of the plant species. Reference articles may be specified to assist in the proper botanical and chemical identification of the plant and plant part. A reference article may be either a USP Authenticated Reference Material, which may be used for both botanical and chemical identification, or a USP Reference Standard, which is used for chemical identification only.

#### USP AUTHENTICATED REFERENCE MATERIALS

USP Authenticated Reference Materials are plant organs or tissues certified to have come from a plant that has been properly identified as belonging to the species listed on the label. The authentication is performed by botanical taxonomists, plant anatomists, phytochemists, or other plant scientists contracted by the USP. A USP Authenticated Reference Material is typically a dried, pulverized plant organ or tissue, and it may be obtained from USP. Herbarium samples that may include roots, stems, leaves, flowers, fruits, and seeds of the authenticated plants are archived and made available for examination upon request. Standard herbarium samples usually consist of the entire mature plant. USP Authenticated Reference Materials undergo the same botanical and chemical diagnostic tests as those applied to the test raw materials. A test article must have all botanical and chemical characteristics specified and found in the USP Authenticated Reference Material. To serve its intended purpose, each USP Authenticated Reference Material is properly stored, handled, and used. Generally, USP Authenticated Reference Materials are stored in their original containers under cool and dry conditions and protected from light and insect infestation. Where special storage conditions are necessary, directions are given on the label. Active principles and marker compounds typically degrade with time; therefore, expiration dates are assigned to USP Authenticated Reference Materials for their use in chemical identification. USP Authenticated Reference Materials are not intended for use in the manufacture of pharmaceuticals, excipients, or dietary supplements.

#### BOTANICAL IDENTIFICATION

The botanical identification of raw plant materials used in the manufacture of pharmaceuticals, excipients, or dietary supplements consists of ascertaining the macroscopic characteristics of the plant part, such as root, stem, leaf, flower, fruit, or seed, used in the manufacture of the article, as well as ascertaining its histological (microscopic) features. It may also include the inspection of organoleptic features of the botanical tissue, such as the presence or absence of a characteristic odor. Individual compendial monographs may include botanical information on possible adulterant species to help ensure their absence in the raw material. For a proper identification of the plant, plant organ, or plant tissue, it is necessary to have a basic knowledge of plant anatomy.

##### Diagnostic Plant Morphology and Anatomy

This section exclusively addresses the diagnostic morphological and anatomical features of vascular plants and the various plant parts, such as roots, stems, leaves, flowers, fruits, and seeds, from which pharmaceuticals, excipients, or dietary supplements are derived. Vascular plants include pteridophytes (ferns and fern allies; for example, genera Aspidium, Equisetum, and Lycopodium), gymnosperms (seed plants, in which the seed is not enclosed within a fruit; for example, genera Ephedra, Gingko, and Pinus), and angiosperms (seed plants, in which the seed is enclosed within a fruit; for example, genera Allium, Digitalis, Panax, Matricaria, and Rauwolfia). Anatomical diagnostic features that are specified in an individual monograph (see Botanic characteristics in individual monographs) may include, but are not limited to, the presence of a particular tissue within an organ; the arrangement and type of cells within a tissue; the presence and type of secretory canal, oil, or resin duct or latexiferous vessels within an organ; the number of epithelial cells surrounding a secretory canal; and the presence and type of ergastic substances such as starch, inulin, fat globules, essential oils, calcium oxalate crystals, cystoliths, polyphenols, fluids, or other materials occurring in the cytoplasm, organelles, vacuoles, cavities, or cell wall.

##### roots

The tissues present in young roots, starting with the most external tissue, include an epidermis with root hairs, cortex, endodermis, pericycle, phloem, xylem, and, in some species, pith. In some species, the outermost layer or layers of cortex are distinct from the inner layers, in which case they are referred to as a hypodermis. In species that undergo secondary growth in the roots, it is typical for all tissues external to the pericycle to be sloughed off. Roots that exhibit secondary growth have a periderm or bark, composed of a phellem (cork), phellogen (cork cambium), and phellem as the outermost tissue. Underneath the periderm, remnants of primary phloem, secondary phloem, vascular cambium, primary xylem, and secondary xylem can be found. Secondary vascular tissues have medullary rays separating clusters of the principal conducting cells of phloem (sieve elements or sieve cells) and the principal conducting cells of xylem (vessels and tracheids). Most species of plants that undergo secondary growth lack pith in the root. The type and arrangement of the principal conducting cells of the vascular tissues may be diagnostic of the species. Roots of many species develop into food storage organs. Abundant parenchyma and large amounts of starch or other polysaccharides characterize these types of roots. The presence, type, and arrangement of fibers, sclereids, and other tissues, and the presence and location of ergastic material may also be diagnostic features. Morphologically, roots may be distinguished from rhizomes (the underground stems) primarily by the absence of nodes and internodes, which are present in rhizomes.

##### stems

Several external macroscopic features of stems that may be diagnostic of the species include the attributes of the nodes, internodes, leaf scars, vascular bundle scars, lenticels, and buds; the growth pattern of the buds; position and arrangement of the leaves along the stem; and the presence of tendrils, spines, thorns, or prickles. Starting with the outermost tissue, the internal arrangement of tissues in the young stems of most species is epidermis, cortex, a concentric ring of vascular bundles separated from each other by parenchymatous medullary rays, and pith. Depending on the species, stomata or trichomes or both structures may be present in the epidermis. The cortex of some species may include a hypodermis or an endodermis or both. In most monocotyledons, the vascular bundles are not arranged concentrically; instead they are scattered throughout a mass of parenchyma tissue internal to

the epidermis. Because of this arrangement, neither cortex, medullary rays, nor pith can be discerned. In woody plant stems that undergo secondary growth, it is typical for the epidermis to be sloughed off and replaced by a periderm composed of a phellem, phellogen, and phelloiderm. Some species are characterized by having multiple periderms (rhytidome). Lenticels may be present in the periderm and their attributes may serve as diagnostic features. Underneath the periderm are the remnants of the cortex, primary phloem, secondary phloem, vascular cambium, and secondary xylem, and the remnants of primary xylem and pith. Medullary rays are also present. As in the root, the type and arrangement of the principal conducting cells of the vascular tissues; the presence, type, and arrangement of fibers, sclereids, and other tissues; and the presence and location of ergastic material may also be diagnostic features. Rhizomes may have some morphological characteristics similar to those of roots and therefore they may be mistaken for roots. However, rhizomes can be correctly identified as stems because they have distinct nodes and internodes.

#### leaves

Several macroscopic features of leaves that may be diagnostic of the species include the attributes of the leaf blade, petiole, and stipules and the phyllotaxy. The outermost tissue of a leaf blade is the epidermis, followed by mesophyll and vascular tissues. Microscopic diagnostic features of epidermal cells include the cuticle thickness and markings, the shape and arrangement of stomata and guard cells, the arrangement and size of subsidiary cells, stomatal number (number of stomata per unit area), and stomatal index (number of stomata per unit number of epidermal cells). Additional features useful in the identification of leaf material include types and arrangement of trichomes (plant hairs) present; type and arrangement of mesophyll and vascular tissues; palisade mesophyll ratio; presence and appearance of accessory tissues such as parenchymatous or sclerenchymatous bundle sheaths, parveinal mesophyll, endodermis, and transfusion tissue; type and arrangement of the principal conducting cells of the vascular tissues; presence, type, and arrangement of fibers, sclereids, and other tissues; and presence, location, and physical appearance of ergastic material.

#### flowers

Flowers are the best diagnostic morphological features of any flowering plant and the floral structure is the principal criterion used in plant taxonomy. The diagnostic features of flowers include type of inflorescence; presence, number, and appearance of the primary floral parts (sepals, petals, stamens, and carpels); type of symmetry displayed by the floral parts; relative position of the ovaries in regards to the other parts of the flower; the number of ovules per ovary; type of placentation of the ovary; physical appearance of the pollen grains; presence of nectaries; presence of covering or glandular trichomes; and physical features of accessory structures, such as the receptacle and bracts. The histological features and the presence of ergastic materials in the tissues of floral parts are also diagnostic of the species.

#### fruits

The identification of the species of plant from which a fruit was derived may be determined by observing several macroscopic criteria. These criteria include the number of pistils found in the fruit, the number of carpels within each pistil, the number of seeds within each carpel, the placentation of the fruit, and the determination whether the fruit is dehiscent, indehiscent, or fleshy. Additional diagnostic features include the number of sutures in a dehiscent fruit, the determination whether the seeds are fused to or free from the pericarp wall, physical features of the three layers of the pericarp of fleshy fruits (epicarp, mesocarp, and endocarp), and presence and physical appearance of accessory tissues such as the receptacle and bracts. Histological features of fruit tissues may aid in identification. The characteristics of the seeds within the fruit are also diagnostic features of the species.

#### seeds

The macroscopic features of seeds used in identification include the shape and size of the seed; appearance of the seed-coat surface; placement of the hilum and micropyle; and presence of accessory structures of the seed coat such as arils, caruncle, or oil bodies. Physical features of the embryo such as its size, shape, position, and the number and appearance of the cotyledons, as well as the presence and appearance of accessory nutritive tissues such as the remnants of a megagametophyte (in gymnosperms), perisperm (nucellus), or endosperm are also diagnostic of the species. Histological features of the seed coat and other structures and tissues of the seed may also be used for species identification.

#### Microtechnique

Histological analysis of botanical specimens can be performed on whole plant material or plant powder. The use of cytological stain or other reagents may be necessary to visualize certain histological features. Crossed polarizers can be used to detect structures that rotate plane-polarized light. These structures include starch grains, calcium oxalate crystals, some fibers, and grains of sand (present as a contaminant) that can be observed as bright objects against a dark background. One polarizer is commonly placed in the condenser or the light source, and the second polarizer is placed in the ocular. Light entering the slide from below is plane polarized, permitting only some light waves in a specific plane to pass through.

When the two polarizers are aligned, the field becomes bright; and when the two polarizers are crossed, the field becomes dark.

#### procedure for temporary mounts and powdered material

General Procedure— Plant samples are observed under the microscope by employing different mounting media, stains, or other solutions to assist in the correct identification of the test article. If a USP Authenticated Reference Material is available, prepare it with the same mounting media or reagent solutions used for the test article. Place one or two drops of water, Glycerin-Alcohol Solution, Chloral Hydrate Solution, or another reagent solution (see Preparation and Use of Reagent Solutions, Optical Devices, and Mountants) in the center of a clean slide. Transfer a small plant tissue section or a portion of plant powder into the mountant or reagent solution, and cover with a clean coverslip. (For specific preparation techniques, see Preparation of Temporary Mounts and Hand Sections, Maceration, or Preparation of Powdered Material, as appropriate.) To prevent the formation of air bubbles, the coverslip may be carefully placed at an appropriate angle with its edge making the first contact with the slide and then pressed until it covers the specimen. Using a piece of filter paper, remove excess fluid from the margin of the coverslip. Air bubbles can be removed by placing the slide in a vacuum desiccator. When using chloral hydrate, air bubbles can be removed by gently boiling the sample over a small flame such as that from an alcohol lamp. To replace the mountant or reagent solution, place drops of the new mountant or reagent solution on one edge of the coverslip. Place a strip of filter paper at the opposite edge of the coverslip to remove the old mountant or reagent solution and to cause the new mountant or reagent solution to be drawn over the powdered material or tissue. Plant oils can be also washed away from the tissue in this manner, when solvent hexane or acetone is washed through the slide followed by water and, if necessary, Chloral Hydrate Solution. Do not use Chloral Hydrate Solution immediately after treating the plant tissue with flammable solvents without thoroughly washing the tissue with water. This is to avoid setting fire to residual solvent when the microscope slide is later placed over a small flame to boil the tissue. Care must be taken when using reagent solutions that are volatile or corrosive to the microscope. To prevent drying of aqueous or chloral hydrate solutions during observation, add a small drop of glycerin to the slide. Observe the mounted sample under an optical microscope (see [Optical Microscopy](#) 776), and examine for histological features.

Preparation and Use of Reagent Solutions, Optical Devices, and Mountants— The following reagents, optical devices, and mounting media are used to assist in the identification of cells, tissues, structural features, and ergastic substances in the tissue or powdered material (see [Tables 1](#) and [2](#)).

Table 1. The Use of Reagent Solutions and Optical Devices

Detection	Reagent Solutions and Optical Devices
Calcium carbonate concretion	Diluted Acetic Acid
Calcium oxalate crystals	Crossed Polarizers
Cellulose	Carmine Alum-Methyl Green Solution Hydriodic Acid Zinc Chloride-Iodine Solution
Cytoplasm	Alcoholic Picric Acid Solution
1,8-Dihydroxyanthra-quinones	1 M Potassium Hydroxide Solution
Essential oils	Osmium Tetroxide Solution Sudan III Solution
Inulin	Naphthol-Sulfuric Acid Solution

Lignin	Carmine Alum–Methyl Green Solution Phloroglucinol–Hydrochloric Acid Solution Universal Reagent
Lipids (cutin, waxes, and suberin included)	Carmine Alum–Methyl Green Solution Osmium Tetroxide Solution Sudan III Solution Universal Reagent
Pectin and mucilage	Ruthenium Red Solution Thionine Solution Toluidine Blue Solution
Phytoglycogen	Ruthenium Red Solution
Protein bodies	Alcoholic Picric Acid Solution Osmium Tetroxide Solution
Saponin	Blood–Gelatin Mixture Iodine–Glycerin Solution (confirm by testing with Blood–Gelatin Mixture)
Starch	Crossed Polarizers Iodine Solution Universal Reagent
Tannins and other polyphenols	Ferric Chloride Solution Osmium Tetroxide Solution

Table 2. Bleaching and Clarifying Agents and Mountants

Use	Mountants and Agents
Bleaching Agents	Sodium Hypochlorite Solution
Clarifying Agents	Chloral Hydrate Solution Lactochloral Solution Lactophenol Solution
Mountants	Glycerin Glycerin–Alcohol Solution Glycerin–Gelatin Mixture Water

Alcoholic Picric Acid Solution— Prepare a 1% solution of picric acid in alcohol. Picric acid is useful to stain cells having dense cytoplasm, such as aleurone cells in seeds. Place a small amount of powdered plant material in a test tube, and shake with about 1 mL of solvent hexane to remove plant oils, which would interfere with the reaction. Centrifuge, and discard solvent hexane. Soak the plant powder in Alcoholic Picric Acid Solution for about 30 minutes. Transfer a portion of the powder to a microscope slide, and observe under a microscope: cytoplasm and protein bodies turn bright yellow. [Caution—Picric acid is explosive when dry. Handle appropriately. ]

Blood–Gelatin Mixture— Add 4.5 g of gelatin powder to 100 mL of a 0.9% sodium chloride solution, and allow to swell for 30 minutes. Heat the gel, while stirring, to about 80° in a water bath. Cool to 40°, and add 6 mL of defibrinated bovine blood. Heat to 45° to 50°, and pour onto a microscope slide in a thin layer of about 1 mm while the slide is in a horizontal position. To prevent loss of blood–gelatin mixture from the sides, seal the microscope slide edge with a 1-cm wide adhesive tape to form a tray. After cooling and solidification, it is ready for use. [note—Store in a humid chamber for not more than 1 to 2 days at 3° to 4°.] To test for saponins, place small clusters of the powdered plant material on the blood–gelatin layer, spacing them a few millimeters apart from each other, transfer to a humidifier for a few hours, and observe: saponin-containing particles will cause light-transparent zones to appear in the blood–gelatin.

Carmine Alum–Methyl Green Solution— Boil 1.5 g of carmine for 30 minutes in a 15% solution of aluminum potassium sulfate. Cool, filter, and add 10 mL of a 0.75% methyl green solution while stirring. Add 1 to 2 drops to plant material: lignin and suberin turn green and cellulose turns red-violet.

Chloral Hydrate Solution— Use chloral hydrate TS. When using the solution as a clarifying agent, add a few drops to the plant material, and boil briefly over a small flame. Chloral hydrate dissolves cellular contents and intercellular substances and allows cell walls and shapes to be easily observed. It can be used to assist in the identification of cork, fibers, vessels, calcium oxalate crystals (with the aid of crossed polarizers), trichomes, stomata, and pollen.

Crossed Polarizers— This optical device is used to detect calcium oxalate crystals and starch grains (amyloplasts). In polarized light, calcium oxalate crystals and starch grains appear as bright, birefringent objects on a dark background. Starch grains observed under polarized light will also have a Maltese-cross effect with the arms of the cross intersecting at the hilum. Calcium oxalate crystals are usually best viewed after the sample has been clarified with Chloral Hydrate Solution or another clarifying agent.

Diluted Acetic Acid— Add 1 to 2 drops to the plant material, and immediately observe under a microscope: calcium carbonate deposits dissolve with effervescence.

Ferric Chloride Solution— Dilute 1 mL of [ferric chloride TS](#) with 9 mL of water. For the detection of phenol hydroxyl groups, such as tannins and flavonoids, from the side of the coverslip add the solution to the aqueous sample: tannins and other polyphenols become blue-black to green.

Glycerin— Use as a mountant to prevent the drying of aqueous and chloral hydrate solutions.

Glycerin–Alcohol Solution— Mix equal volumes of glycerin and alcohol. Use as a mounting medium.

Glycerin–Gelatin Mixture— Add 10.0 g of powdered gelatin to 60 mL of water. Allow to stand for 2 hours, and add 70 mL of glycerin containing 1.5 g of dissolved phenol. Heat in a water bath, and filter through a preheated funnel containing glass wool. The filtered mixture is liquefied before use, and it serves as a mounting medium. Add a few drops to the cut or powdered plant material, and cover with a heated coverslip. This preparation is used for long-term storage of specimen mounts. The margins of the coverslip may be sealed with Canada balsam after a few months of drying.

Hydriodic Acid— Add 1 to 2 drops to plant material: cellulosic cell walls become blue to blue-violet.

Iodine Solution— Add 1 to 2 drops of 0.1 N iodine VS to the plant material: starch particles become dark-blue to blue-violet; this reaction is reversible on heating. [note—Proteins, lipids, and cellulose turn yellow to brown; and guaiac powder particles become green to blue, but this reagent is not used for diagnostic identification of these features.]

Iodine–Glycerin Solution— Dissolve 0.3 g of iodine and 1.0 g of potassium iodide in a small quantity of water, and add 10 mL of a mixture of glycerin and water (1:1). Add 1 to 2 drops to the powdered plant material: samples containing saponins form yellow lumps or aggregates. If a sample tests positive for saponin, the result has to be confirmed by testing the sample with Blood–Gelatin Mixture as well.

Lactochloral Solution— Dissolve 50.0 g of chloral hydrate in 50 mL of lactic acid with gentle heating. Add a few drops to the plant material. Place the microscope slide in a small vacuum desiccator if it is necessary to eliminate air bubbles. Chloral Hydrate Solution and Lactochloral Solution are used for the same type of identification, except that Lactochloral Solution is a stronger clarifying agent and it is used for plant material that is more difficult to clarify.

Lactophenol Solution— Mix 20 g of lactic acid, 40 g of glycerin, and 20 mL of water. Add 20 g of phenol, and mix. This is a strong clarifying agent suitable for the examination of pollen

grains.

Naphthol-Sulfuric Acid Solution— Prepare a 20% solution of 1-naphthol in alcohol. To plant material add 1 drop of 1-naphthol solution and 1 drop of sulfuric acid: inulin crystals turn brownish red and then dissolve.

Osmium Tetroxide Solution— Dissolve 0.1 g of osmium tetroxide in 5 mL of distilled water. Add 1 to 2 drops of the solution so obtained to plant material: essential oils, fatty oils and other lipids, tannins, and protein bodies become brown to black.

Phloroglucinol-Hydrochloric Acid Solution— This solution is used for the identification of lignin and other hydroxyphenylpropane derivatives, lignified tissues such as sclereids, vessels, fibers, and stone cells, and lignified parenchyma. Moisten the powder or the cut sample with [phloroglucinol TS](#), and allow to dry for 2 to 3 minutes before placing the coverslip. Add a few drops of a 25% hydrochloric acid solution, and cover with the coverslip. Lignified cell walls turn carmine red. [note—This stain is not stable.] Cells with hydroxyphenylpropane derivatives, such as vanillin and ferulic acid, also turn red. Alternatively, hydroxyphenylpropane derivatives can be extracted from the plant material and the plant material then examined. To extract hydroxyphenylpropane derivatives repeatedly immerse the untreated material in alcohol, mix on a vortex mixer, centrifuge, and discard the alcohol between washings. Then treat the plant material as specified above, beginning with the addition of phloroglucinol TS.

1 M Potassium Hydroxide Solution— Add 1 drop to plant material: cells containing 1,8-dihydroxyanthraquinones will stain red.

Ruthenium Red Solution— Add a few drops of ammonium hydroxide to [ruthenium red TS](#). [note—Store the solution protected from light.] Add 1 to 2 drops to plant material: pectin-containing cell membranes, acidic mucilage, and phytoglycogen turn red.

Sodium Hypochlorite Solution— This solution is used to bleach deeply colored sections. Immerse the plant material in the solution for a few minutes until sufficiently bleached. Wash the tissue with water, and mount with a suitable mounting agent. [note—Sodium hypochlorite will extract lignin; plant tissue so treated will test negative for lignin.]

Sudan III Solution— Dissolve 0.5 g of Sudan III in 50 mL of alcohol or isopropyl alcohol with reflux boiling. Cool, filter, and add 50 mL of glycerin. Add 1 to 2 drops of this solution to plant powder: essential oils, waxes, cutin, suberin, and fatty oils and other lipids combine with this lipophilic colorant and become orange-red to red after a short time.

Thionine Solution— Prepare a 0.2% thionine acetate solution in 25 percent alcohol. Immerse the dry sample in this solution. After about 15 minutes, wash out the excess of stain with 25 percent alcohol: mucilage will have swollen into spherical globules and turned red-violet, while cellulose, pectin, and lignified septa will turn blue or blue-violet.

Toluidine Blue Solution— Using toluidine blue, proceed as directed for Thionine Solution.

Universal Reagent—

solution a— Dilute 20 mL of a lactic acid-saturated solution of Sudan III with 30 mL of lactic acid.

solution b— Dissolve 0.55 g of aniline sulfate in 35 mL of water.

solution c— Dissolve 0.55 g of potassium iodide and 0.05 g of iodine in 5 mL of water, and add 5 mL of alcohol.

procedure— Combine Solution A, Solution B, and Solution C, and add 2.5 mL of hydrochloric acid while stirring. [note—The solution is used without filtering.] For identification, add 2 to 3 drops to the sample, and gently boil over a small flame. If necessary, small amounts of Universal Reagent may be added during boiling. Cover with the coverslip: lignified elements turn yellow; suberin turns red-brown; lipids turn red; and starch turns blue-violet.

Water— Use as a mounting medium. [note—All grades of water are acceptable for this purpose.]

Zinc Chloride-Iodine Solution— Dissolve 20.0 g of zinc chloride and 6.5 g of potassium iodide in 10.5 mL of water. Add 0.5 g of 0.1 N iodine VS, and shake for 15 minutes. Filter if necessary. Store in low-actinic glassware. Add 1 to 2 drops to plant material, and allow to stand for a few minutes: cellulosic cell walls are stained blue to blue-violet.

Preparation of Temporary Mounts and Hand Sections— When using the dry plant tissue, soak or gently boil in water until soft. Do not soften too much. Material can then be treated like fresh plant material. When appropriate, use the mountants or reagent solutions listed for use with plant powder to help visualize features of the tissue (see Preparation and Use of Reagent Solutions, Optical Devices, and Mountants).

To make an epidermal peel of the leaf, petal, sepal, bract, and other leaf-like appendages, roll the tissue into a cylinder, and nick with a sharp, polytef-coated razor blade that has been wetted with water. Grasp nicked piece of tissue with forceps, and strip back removing a clear section of the epidermis. Mount in water on a microscope slide, place a coverslip over the tissue, and examine under a microscope. If it is difficult to obtain an epidermal peel using the above procedure, proceed as follows. Soak the tissue in a 40% to 60% nitric acid solution at 60° for 3 to 4 minutes or until the epidermis can be easily peeled. The peel is then washed three to five times in water to remove the excess of nitric acid. Neutralize the tissue in a 1% potassium hydroxide solution or a 1% sodium hydroxide solution. Wash the tissue again with water, mount in water on a microscope slide, place a coverslip over the tissue, and examine under a microscope.

An alternative method of preparing leaf tissue for the examination of the epidermis is to heat a leaf fragment (about 5 mm × 5 mm) for 15 minutes in Chloral Hydrate Solution on a water bath. Transfer the tissue to a microscope slide, add a drop of water, and cover with a coverslip. These procedures can be used to determine the stomatal type, distribution, number, and index.

Stomatal number is determined by counting the number of stomata per unit area of a microscopic field. Determine the stomatal number on at least 10 different sites of the specimen, and calculate a mean value. Keep track of which leaf surface is being observed, abaxial or adaxial, as the stomatal number for different surfaces is frequently significantly different.

To calculate the stomatal index, the specimen is observed under a microscope at a low magnification. The size of the surface is determined with a calibrated micrometer ocular, and the number of stomata and the number of epidermal cells for that area are determined. The stomatal index is calculated by the formula:

$$100S/(E + S)$$

in which S is the number of stomata for a given area, and E is the number of epidermal cells of the same area. Determine the stomatal index on at least 10 different sites of the specimen, and calculate a mean value. Again, keep track of which leaf surface is being observed, abaxial or adaxial, as the stomatal indices for different surfaces is frequently significantly different.

To make a cross section of a leaf or thin roots, stems, or other thin appendages, lay the appendage to be sectioned on a microscope slide. Place another microscope slide over the appendage with a portion of the tissue exposed. Using a sharp, polytef-coated razor blade that has been wetted, cut straight down along the edge of upper slide. Without moving the upper slide, cut down again with the razor blade at an angle. Some practice may be necessary for one to be able to get sections thin enough so that when they are mounted and covered with a coverslip, these sections can be used to determine tissue arrangements (for instance, the number of palisade layers in leaf, thickness of cuticle, types of trichomes, types of vascular bundles, and the like). Because razor blades dull quickly, they have to be replaced frequently.

Use the cross section of leaf tissue so obtained to determine the palisade mesophyll ratio. Alternatively, boil leaf fragments of about 2 mm<sup>2</sup> in Chloral Hydrate Solution, mount, cover with a coverslip, and observe under a microscope. Identify groups of four adaxial epidermal cells, and count the palisade mesophyll cells that are lying below and are at least 50% covered by the epidermal cells. This value divided by 4 is the palisade mesophyll ratio. Determine the palisade mesophyll ratio of at least 10 groups of epidermal cells, and calculate a mean value. Palisade mesophyll ratio can also be determined on powdered leaf material.

To make a cross section of thick stems, roots, or other plant parts, including woody tissues, hold the tissue in one hand and using a sharp, polytef-coated razor blade that has been wetted with water, shave a cross section from the appendage. Mount in water, another medium, or reagent solution, place a coverslip over the material, and examine under a microscope. Sections thin enough to determine vascular tissue arrangement, ray type, parenchyma distribution, presence of crystals, and the like can usually be made with a little practice.

Maceration— It is sometimes necessary, for the proper identification of a plant material, to macerate the tissue into its individual cells before microscopic examination. This can be an especially useful technique for woody or other hard tissues. The material is cut into small pieces of about 2-mm thickness and 5-mm length or sliced into pieces of about 1-mm thickness. Depending on the nature of the cell wall, one of the following methods is used. For hard or highly lignified tissues, use Method I. For tissues that are not extensively lignified, use Method II.

**Method I—**

solution a—Use 4 N nitric acid solution.

solution b—Prepare a mixture of 1.2 M chromium trioxide solution and sulfuric acid (7:4).

procedure—Place the plant material in a test tube containing about 5 mL of a mixture of Solution A and Solution B (1:1). Heat in a water bath for 20 minutes. Wash the tissue repeatedly with water, and transfer to a microscope slide. Tease tissue apart with dissecting needle, add 1 to 2 drops of mountant, cover with a coverslip, and examine under a microscope. If necessary, cells can be further separated from each other by pressing down on the coverslip with a gentle, sliding motion. The macerated tissue will test negative for lignin.

**Method II—**

procedure—Place the plant material in a test tube containing about 5 mL of 2 M potassium hydroxide solution. Heat in a water bath for 30 minutes. Wash the tissue repeatedly with water, and transfer to a microscope slide. Add 1 to 2 drops of mountant. Place a coverslip over the tissue, press down, squashing the tissue, and examine under a microscope. The macerated tissue will test negative for lignin.

**Preparation of Powdered Materials**—Place one or two drops of water, another mountant, or a reagent solution in the center of a clean slide. Moisten the tip of a dissecting needle with water, and dip into the powder under test. Transfer a small amount of material that adheres to the needle into the fluid on the slide, and stir thoroughly and carefully. Cover with a clean coverslip. Because the arrangement of the tissue structures within the plant tissue has been destroyed, the important features for observation of the powdered plant material are the chemical and physical features of tissues and cell types, as well as the presence and chemical and physical features of ergastic substances. The specific tissues, cells, and ergastic substances to be examined are specified in the individual monograph.

**procedure for thin, permanent mounts**

When it is necessary to reveal detailed histological features of a plant specimen, thin tissue sections have to be obtained. The sections need to be thin enough to transmit light and they have to be cut in such a plane that the desired features are exposed. The plant material is properly killed, fixed, dehydrated, and embedded in paraffin or other embedding media. The embedding medium is used as a solid-support matrix during tissue sectioning. After sectioning and mounting, staining of the specimen is frequently performed to aid in the differentiation of certain structures. [note—The process of fixing, dehydration, embedding, and staining can be significantly expedited by utilizing a microwave oven specifically designed for histological work.]

**Killing and Fixation**—As a first step in preparing plant material for sectioning, living cells are killed, and the tissue is preserved. This is most frequently done by employing a chemical fixative. A good general purpose fixative for plant material is a mixture of formaldehyde, acetic acid, and alcohol (FAA).

**FAA Solution**—Mix 50 mL of alcohol, 5 mL of glacial acetic acid, 10 mL of formaldehyde solution, and 35 mL of water. [note—Periodically prepare fresh solution, as it loses effectiveness with storage.]

**Procedure**—Completely immerse the plant material in FAA Solution. Allow the material to remain immersed for 18 to 24 hours at room temperature. Plant material can be kept indefinitely in FAA Solution, as long as it remains completely immersed and is not allowed to dry out. Certain plant tissues may require vacuum infiltration to facilitate the penetration of the fixative. Vacuum infiltration is required if the tissue has abundant air spaces or epidermal hairs or if it floats on top of the fixative solution. Place the tissue in a small vial containing the fixative. Place the uncapped vial into a bell jar or desiccator that is connected to a vacuum source, preferably an oil-sealed vacuum pump. The vacuum is vented into a fume hood to prevent fixative vapors from filling the room. Slowly turn on the vacuum. Do not use a strong vacuum because the fixative may start to boil and damage the tissue. As residual air is pulled from the tissue, it will rise to the surface. Turn the vacuum on and off through several cycles until the tissue stays at the bottom of the container during an "on" cycle.

**Tissue Dehydration**—Paraffin and other embedding media are hydrophobic; thus, water must be removed from the plant tissue after fixation. This is accomplished by immersing the fixed tissue in dehydration solutions, which are a series of mixtures of alcohol and water with increasing alcohol concentration. The final solution in the series is dehydrated alcohol. Begin by washing the fixed tissue once or twice with fresh 50 percent alcohol to remove traces of FAA. Remove this solution, and subsequently remove any other dehydration solution, by decanting the solution or removing it with the aid of a glass pipet. Add the first dehydration solution (70 percent alcohol) to the vial, completely immersing the tissue. The graded alcohol-water series and the suggested times for tissue immersion are as follows.

Dehydration Solution	Time (hours)
50 percent alcohol	1–2
70 percent alcohol	1–2
90 percent alcohol	1–2
95 percent alcohol	1–2
Dehydrated alcohol containing 0.1% of safranin O	
safranin O	2–4
Dehydrated alcohol	1

Safranin O is added to the penultimate dehydration solution in the series to visualize the tissue when it has become embedded in paraffin. If the tissue to be sectioned is hard or woody, the time for each step in the series may need to be increased to up to 24 hours. If necessary, the tissue can be stored for several days in 70 percent alcohol or in solutions of even higher alcohol concentrations.

**Embedding—****Preparation for Embedding—**

**alcohol removal**—Paraffin is the most common embedding medium, although other embedding media are available. After dehydration, alcohol is removed from the tissue by using a graded series of dehydrated alcohol-xylene solutions, because paraffin is not soluble in alcohol. The graded dehydrated alcohol-xylene series and the suggested times for tissue immersion are as follows.

Alcohol Removal Solution	Time (hours)
A mixture of dehydrated alcohol and xylene (3:1)	1
A mixture of dehydrated alcohol and xylene (1:1)	1
A mixture of dehydrated alcohol and xylene (1:3)	1
Xylene	1
Xylene	1

**xylene removal**—Once xylene has completely replaced alcohol, paraffin is added slowly to infiltrate the tissue and remove xylene. Proceed as follows:

1. For each mL of xylene add about 1 paraffin chip to the tissue vial, cap, and allow to stand at room temperature for 4 hours. Add additional paraffin chips until no more chips dissolve.
2. Place tissue in an oven maintained at 42° to 45°. Add 2 to 3 paraffin chips every hour until no more chips dissolve at that temperature.

3. Pour off one-third of the volume, and replace with an equal volume of melted paraffin. Do not cap, and transfer vial to an oven maintained at 58° to 60°.
4. After the paraffin remelts (about 4 hours later) pour off one-half of the volume, and replace with equal volume of melted paraffin. Transfer vial to the oven maintained at 58° to 60° if paraffin begins to solidify.
5. Repeat step 4 twice more, then pour off the entire volume of paraffin-xylene. Replace with pure melted paraffin. About 4 hours later, pour off paraffin, and replace with fresh pure melted paraffin. Repeat the pouring off and replacement 4 hours later, and allow to stand overnight. [note—Transfer vial to the oven maintained at 58° to 60° if paraffin begins to solidify at any point.]

**Embedding Procedure**— Pour the tissue with the paraffin to an embedding boat. Paraffin has to completely cover the tissue by about 3 to 5 mm. Place the embedding boat on top of a preheated warming platform that is designed for histology work. Adjust the tissue in the boat to its proper orientation for sectioning. Slowly cool the paraffin by sliding the boat down to the cool side of the platform until the paraffin has solidified. Immerse the paraffin block in ice water to rapidly cool the block and to prevent paraffin crystals from forming. Store the paraffin block at 4°.

**Sectioning and Mounting**— Cut the paraffin block into pieces, each containing one tissue sample. Trim the paraffin block, as close to the tissue mass as possible, to form a rectangle or a slight trapezoid. Such trimming will prevent sectioning problems due to excess paraffin around the tissue. To make transverse sections, orient the tissue at a right angle to a wooden tissue block whose face has been soaked in melted paraffin. Affix the paraffin block to the face of the tissue block. Add a small amount of melted paraffin to the base of the paraffin block to help form a tighter seal. Cool the block to 4°.

Properly mount and adjust the tissue and paraffin block in a microtome. Use a sharp stainless-steel microtome knife that has been properly honed. Set the microtome to cut sections 8 to 15 µm thick (10-µm thickness is optimal for most tissues). Cut individual or serial sections. Prepare a microscope slide as follows. An adhesive may be prepared as a solution containing 1% of gelatin and 0.5% of sodium benzoate that is heated to 30° to 35° to dissolve the gelatin. Smear a thin film of the adhesive so obtained onto the slide, allow to dry, rinse with a 4% solution of formaldehyde TS, and add a small amount of water. Plate the cut sections upside down on the slide, so that they float on water, and flood with a 4% solution of formaldehyde TS. The sections will immediately spread out and wrinkles will disappear.

Place the slide on a warming platform, maintained at 42°, to relax the sections. Pipet, and blot the excess water and formaldehyde solution. Dry overnight in an oven at 42° to ensure adherence of the tissue section to the slide.

#### Staining—

**Preparation for Staining**— Immerse the microscope slide with the affixed tissue twice into xylene, each time for 10 to 15 minutes, to remove paraffin. Then immerse the slide into several solutions, leaving it in each solution for 5 minutes and taking care not to dislodge the tissue, the following sequence of solutions being used: a mixture of dehydrated alcohol and xylene (1:1), dehydrated alcohol, alcohol, and a 70 percent alcohol solution. The tissue is bleached prior to staining if it is opaque because of the presence of tannins or other ergastic materials. To bleach, dip the slide into a 1% potassium permanganate solution for 1 minute, rinse with water, dip into a 5% oxalic acid solution for 1 minute, and rinse thoroughly with water. The material is ready for staining. One of the following two staining procedures is recommended for most botanical identification work. The first staining procedure uses safranin O counterstained with fast green. An alternative staining procedure uses safranin O counterstained with orange G.

#### Safranin O-Fast Green Staining—

**safranin o staining solution**— Prepare a mixture of methoxyethanol, dehydrated alcohol, water, and formaldehyde solution (50:25:25:2). Add a sufficient quantity of sodium acetate to obtain a solution containing 1% of sodium acetate, and mix. Add a sufficient quantity of safranin O to obtain a solution containing 1% of safranin O, and mix.

**fast green staining solution**— Prepare a mixture of methoxyethanol, dehydrated alcohol, and methyl salicylate (1:1:1) containing 0.05% of fast green FCF.

**procedure**— Once the tissue has been rehydrated to 70 percent alcohol as described under Preparation for Staining, immerse for 2 to 24 hours, depending on the tissue, in Safranin O Staining Solution. Remove excess stain by immersing the slide in water several times. Transfer slide to an alcohol solution containing 0.5% of picric acid for 2 to 10 seconds to further remove excess stain from the section and to assist in differentiation of the tissue structures. To stop the action of the picric acid, transfer slide for 10 seconds to 1 minute to an alcohol solution containing 4 drops of ammonium hydroxide in each 100 mL of alcohol. Transfer slide to dehydrated alcohol for 10 seconds. Visually inspect the stained tissue under a microscope to see if further destaining with picric acid is necessary. Counterstain for 10 to 15 seconds in Fast Green Staining Solution. Transfer slide through two changes of a mixture of methyl salicylate, dehydrated alcohol, and xylene (2:1:1), each change lasting for 5 to 10 seconds. Then transfer slide to a mixture of xylene and dehydrated alcohol (95:5) for 1 minute. Transfer through two changes of xylene. Store in xylene until ready to mount the coverslip. Chromosomes, nuclei, and lignified, cutinized, or suberized cell walls will be stained red. Cytoplasm and cellulosic cell walls will be stained green to blue, depending on the pH of the tissue.

#### Safranin O-Orange G Staining—

**safranin o staining solution**— Prepare a 0.004% solution of safranin O.

**orange g staining solution**— Dissolve 2 g of orange G, 5 g of tannic acid, and 4 drops of hydrochloric acid in water, and dilute with water to 100 mL.

**procedure**— Once the tissue has been rehydrated to 70 percent alcohol as described under Preparation for Staining, sequentially transfer slide through the following series of solutions.

Solution	Time
35 Percent alcohol	5 minutes
A filtered 2% zinc chloride solution	1 minute
Water	5 seconds
Safranin O Staining Solution	5 minutes
Water	5 seconds
Orange G Staining Solution	1 minute
Water	5 seconds
A filtered 5% tannic acid solution	5 minutes
Water	3 seconds
A 1% ferric ammonium sulfate solution	2 minutes
Water	15 seconds
45 Percent alcohol	10 seconds
90 Percent alcohol	10 seconds
Dehydrated alcohol	10 seconds
A mixture of dehydrated alcohol and xylene (1:1)	1 to 2 minutes

Finally, store in xylene until ready to mount the coverslip. Cellulosic cell walls will stain blue-black, nuclei will stain yellow, starch grains will stain black, and lignified cell walls will stain red.

**Mounting the Coverslip**— The mounting of a coverslip over the tissue completes the preparation of the slide. Canada balsam, diluted with a small portion of xylene, can be used as an adhesive. Other mountants are also commercially available. Upon drying of the mountant, the slide can then be examined under a microscope. The entire process of making permanent microscope slides can be expected to take 5 or more days.

## CHEMICAL IDENTIFICATION

To help ensure the authenticity of the article, chemical identification is performed in conjunction with botanical identification outlined above. Chemical identification typically employs chromatographic procedures to detect the presence of marker compounds specified in the individual monograph. Spectroscopic or chromatographic profiles can be used to achieve chemical identification by fingerprint comparison against that of a reference sample or standard. Examples of spectroscopic method include UV, IR, and Fourier transformed IR (see [Spectrophotometric Identification Tests](#) (197)). Examples of chromatographic methods include high-pressure liquid chromatography (HPLC), thin-layer chromatography (TLC), 2-dimensional-TLC, and gas chromatography (see [Chromatography](#) (621)). Analytical methods used for fingerprinting should be capable of detecting as many chemical constituents as possible. Multiple fingerprints, using a combination of analytical methods with different separation principles and test conditions, may be useful. In addition to the spectroscopic chromatographic methods, qualitative wet-chemistry methods may also be specified in the individual monograph.

### Chemotaxonomy

Chemotaxonomy is the classification of the plants based on their chemical constituents and it may be useful in botanical articles identification. Metabolic compounds found within plant tissues can be divided into two broad categories based on their functions. The first category comprises primary metabolites—metabolites involved in the physiological plant processes that are absolutely necessary for life and ubiquitous throughout the plant kingdom. These processes include photosynthesis, respiration, and nucleic acid, protein, carbohydrate, and lipid metabolism. The second category comprises secondary metabolites—compounds that are thought not to be absolutely necessary for plant processes, although they may have important functions in the plant's interactions with other organisms, such as allelopathic interactions; in chemical defense against herbivores and plant pathogens; and in signaling to attract pollinating and seed-dispersing animals. Many secondary metabolites are known to have pharmacological activity. They are also the basis for the chemotaxonomy of plants.

Secondary metabolites fall into several different chemical classes such as nonprotein amino acids, flavonoids, xanthones, coumarins, polyacetyles, cyclic polyketides, monoterpenes, sesquiterpenes, iridoids, triterpenes, sterols, nitrogen-containing terpenes, and alkaloids. These chemical classes are not ubiquitous throughout the plant kingdom, but tend to be specific to certain botanical classes, orders, and families. Moreover, many chemical subclasses and individual secondary compounds are specific to certain subfamilies, genera, or species. It is these chemical subclasses and individual compounds that can be used as marker compounds to aid in the proper identification of plant material.

### Active Principles and Marker Compounds

For chemical identification of botanical articles, extracts are prepared. Such extracts are usually complex mixtures of several chemical constituents. For a large majority of botanical extracts it is not known with certainty which of the various components is responsible for the reported pharmacological effect. It is generally believed that several constituents act synergistically to provide the reported effect. For articles for which compendial monographs are provided, certain chemical constituents of the article are chosen and quantitative test procedures for determining their content are provided. The choice of such constituents, known generally as marker compounds, is based on certain considerations. Currently, the following types of marker compounds are specified in compendial monographs and may be identified in raw materials:

**Active Principles**— These are constituents that have proven clinical activity. A minimum content or range for the active principles is usually specified in the individual monograph. A quantitative determination of active principles during stability studies of botanical dosage forms provides necessary information for arriving at suitable expiration dates.

**Active Markers**— These are constituents that have known pharmacological activity contributing in some extent to efficacy. However, the clinical efficacy for these constituents may not be proven. A minimum content or range for active markers is usually specified in individual monographs. A quantitative determination of active markers during stability studies of botanical dosage forms provides necessary information for arriving at suitable expiration dates.

**Analytical Markers**— Where neither defined active principles nor active markers are known, other constituents of the botanical extract amenable to quantitative determination are chosen. These markers aid in the positive identification of the article under test. In addition, maintaining a minimum content or a specified range of the analytical markers helps to achieve standardization of the plant extract and to arrive at a suitable expiration date during stability studies.

**Negative Markers**— These are constituents that may have allergenic or toxic properties, rendering their presence in the botanical extract undesirable. For example ginkgolic acids from ginkgo belong to this category. A stringent limit for these negative markers may be specified in individual monographs.

### Use of USP Reference Articles

Reference articles are used to assist in the identification of marker compounds within the test article. Reference articles are either USP Authenticated Reference Materials or USP Reference Standards (see [USP Reference Standards](#) (11)), whichever is specified in the individual monograph. USP Reference Standards used to identify marker compounds in the test articles may be a single purified chemical entity, a mixture of purified chemical entities, or a standardized extract prepared from the authenticated plant article. USP Reference Standards may also be used to quantitate marker compounds, as specified in the individual monograph.

A pulverized test article undergoes a specified extraction procedure (see [Methods of Extraction under Botanical Extracts](#) (565)) and is prepared for chromatographic or wet-chemistry analysis. If a USP Authenticated Reference Material is available, then it undergoes the same extraction procedure as the test article. The test preparation and reference articles then undergo the same chromatographic or wet-chemistry procedure specified in the individual monograph. The response of the test preparation is compared to the response of reference articles to determine the presence of the marker compounds in the test article.

Auxiliary Information— Please [check for your question in the FAQs](#) before contacting USP.

Pharmacopeial Forum: Volume No. 28(2) Page 435

### 565 BOTANICAL EXTRACTS

In the extraction practice for articles of botanical origin, the constituents of interest are completely or partially separated from other components with the aid of water, alcohol, alcohol-water mixtures, or other suitable solvents. This extraction process involves the removal of the desired constituents from the plant matter with suitable menstrua, the evaporation of all or nearly all of the solvent, and the adjustment of the residual fluids, masses, or powders to the prescribed standards. Suitable inert substances may be added as carriers or diluents to improve physical characteristics. Suitable antimicrobials and other preservatives may be added to preserve the integrity. Extracts may be subjected to processes that increase the content of characterized constituents, decrease the content of unwanted constituents, or both. Extracts with no added inert substances and no processing beyond the extraction are called native extracts. In some preparations, the plant matter may be pretreated by inactivation of enzymes and microbial contaminants, grinding, defatting, or a similar procedure. Extracts may be defined as preparations with liquid, solid, or semisolid consistency. The products obtained by extraction are fluidextracts, powdered extracts, semisolid extracts, and tinctures.

## METHODS OF EXTRACTION

### Percolation

In the manufacture of extracts, percolation is a commonly used method. The crude material being extracted is reduced to pieces of suitable size, if necessary, then mixed thoroughly with a portion of the specified solvent, and allowed to stand for about 15 minutes. The mixture is transferred to a percolator, sufficient amount of the specified solvent is added to cover the entire solid mass, and the mixture is allowed to percolate slowly (at a rate of not more than 1 mL per minute for 1000 g of material), the matter to be extracted being always covered with a layer of solvent. The residue may be pressed, and the obtained fluid is combined with the percolate. The entire percolates are concentrated, generally by distillation under reduced pressure, so as to subject the constituents of interest in the article under extraction to as little heat as possible.

## Maceration

Unless otherwise specified, the crude material being extracted is reduced to pieces of suitable size, mixed thoroughly with the specified extracting solvent, and allowed to stand at room temperature in a closed container for an appropriate time, with frequent agitation until soluble matter is dissolved. The mixture is filtered, the insoluble material is washed with the same solvent used for maceration, and the filtrates are combined and concentrated, usually under reduced pressure, to the desired consistency.

## PREPARATIONS

### Fluidextracts

Fluid extracts, also known as liquid extracts, are preparations of plant matter, containing alcohol as a solvent or as a preservative, or both, and are so made that each mL contains the extracted constituents of 1 g of the crude material that it represents, unless otherwise specified in the individual monograph. They may be prepared from suitable extracts and may contain suitable antimicrobial or other preservatives.

Pharmacopeial fluidextracts are made by percolation, often following a period of maceration. The required solvent is specified in the individual monograph. The common manufacturing procedure includes concentration of the more diluted portion of percolate by evaporation or distillation under vacuum at temperatures below 60°. The time of maceration and the rate of flow during percolation may be varied to adjust for the quantity and nature of the crude material under extraction, provided that the composition of the extracted constituents of interest is not adversely affected.

The rate of flow of the percolate can be slow, moderate, or rapid. With reference to the extraction of 1000 g of the starting material, at a slow rate, not more than 1 mL of percolate is produced per minute; at a moderate rate, between 1 and 3 mL per minute is produced; and at a rapid rate, between 3 and 5 mL per minute is produced. A fluidextract that tends to deposit sediment may be aged and filtered, or the clear portion may be decanted, provided that the resulting clarified liquid conforms to the Pharmacopeial standards.

### Powdered Extracts

Powdered extracts are solid preparations having a powdery consistency obtained by evaporation of the solvent used for extraction. They may contain suitable added substances such as excipients, stabilizers, and preservatives. Standardized powdered extracts are adjusted to the defined content of constituents, using suitable inert materials or a powdered extract of the plant matter used for preparation. Where applicable, a limit for the solvent used for extraction is specified in the individual monograph.

### Semisolid Extracts

Semisolid extracts, also known as soft extracts or pillular extracts, are preparations having consistencies between those of fluidextracts and those of powdered extracts, and are obtained by partial evaporation of the solvent, water, alcohol, or hydroalcoholic mixtures being used as extracting solvents. They may contain suitable antimicrobial or other preservatives. A semisolid extract and a powdered extract obtained from the same material are interchangeable as drugs or as supplements, but each has its own advantages.

### General Pharmacopeial Requirements

Unless otherwise specified in the individual monographs, Pharmacopeial requirements for the fluidextracts, powdered extracts, and semisolid extracts are as follows.

**Packaging and Storage**— Store in tight, light-resistant containers. [note—See Preservation, Packaging, Storage, and Labeling under General Notices and Requirements.]

**Labeling**— Label it to indicate the name of the plant part used; the names of solvents, other than the hydroalcoholic solvents, used in preparation; the content, in percentage, of active principles or marker compounds identified in the individual monograph; and the name and concentration of any added antimicrobial or other preservative. Where active principles are unknown, the ratio of starting material to final product is stated. For semisolid extracts and powdered extracts, the identity and quantity of any added excipient is also indicated. In such cases the percentage of native extract may also be stated.

**Residue on Evaporation**— Transfer promptly about 2 mL, accurately measured, of Fluidextract, about 0.5 g of Powdered Extract, or about 2 g of Semisolid Extract to a suitable tared, round-bottom flask. Evaporate to dryness on a water bath, and dry the residue at 100° to 105° for 3 hours. Allow to cool in a desiccator over phosphorus pentoxide, and determine the weight of the residue obtained: not less than 95% of Powdered Extract specimen remains as residue; or not less than 70% of Semisolid Extract specimen remains as residue. [note—Limits for Fluidextracts are specified in the individual monographs.]

**Residual Solvents**— If prepared with solvents other than alcohol, water, or alcohol-water mixtures, it meets the requirements for [Residual Solvents](#) (467). [note—See ICH document Impurities: Residual Solvents for related information.]

**Pesticide Residues**— Proceed as directed under [Articles of Botanical Origin](#) (561): meets the requirements.

[Heavy Metals, Method II](#) (231): 20 µg per g.

[Alcohol Content, Method II](#) (611) (if present): between 90% and 110% of the labeled amount of C2H5OH is found in Fluidextract and Semisolid Extract.

### Tinctures

Tinctures are liquid preparations usually prepared by extracting plant materials with alcohol or hydroalcoholic mixtures. Traditionally, tinctures of potent articles of botanical origin represent the activity of 10 g of the drug in each 100 mL of tincture, the strength being adjusted following the test for content of active principles or marker compounds. Most other plant tinctures represent 20 g of the respective plant material in each 100 mL of tincture.

Different tinctures are not always diluted to obtain the same ratio of starting plant material to final tincture. This ratio will depend on the requirements prescribed in the specific tests for content of active principles or marker compounds included in the individual monographs. As tinctures are being prepared, they are assayed in accordance with these content tests.

Using the values obtained from such assays, the final concentration of a tincture is adjusted by adding more solvent or by evaporating part of the solvent.

Unless otherwise specified, tinctures are usually prepared from coarse powder or fine cuttings of plant materials either by a percolation process or a maceration process.

### percolation process

Carefully mix the ground mixture of ingredients with a sufficient quantity of the prescribed extracting solvent to render it evenly and distinctly damp, allow it to stand for 15 minutes, transfer it to a suitable percolator, and pack the mass firmly. Pour on enough of the specified extracting solvent to saturate the drug, and cover the top of the percolator. When the liquid is about to drip from the percolator, close the lower orifice, and allow the drug to macerate for 24 hours or for the time specified in the monograph. If the test for content of active principles or marker compounds is not required in the individual monograph, allow the percolation to proceed slowly or at the specified rate (for definitions of flow rates, see under [Fluidextracts](#)), gradually adding sufficient quantity of extracting solvent to produce 1000 mL of tincture, and mix. If a test for content of active principles or marker compounds is required, collect only 950 mL of percolate, mix, and test a portion of it as directed in the individual monograph. Dilute the remainder of the percolate with as much of the prescribed extracting solvent as calculation from the content test indicates is necessary to produce a tincture that conforms to the requirements, and mix.

### maceration process

Macerate the drug with 750 mL of the prescribed extracting solvent in a closed container, and put in a warm place. Agitate it frequently during 3 days or until the soluble matter is dissolved. Transfer the mixture to a filter. When most of the liquid has drained, wash the residue on the filter with a sufficient quantity of the prescribed extracting solvent, combining the filtrates, to produce 1000 mL of tincture, and mix.

### general pharmacopeial requirements

Unless otherwise specified in the individual monographs, Pharmacopeial requirements for the tinctures are as follows.

**Packaging and Storage**— Store in tight, light-resistant containers, and avoid exposure to direct sunlight and excessive heat. [note—See Preservation, Packaging, Storage, and Labeling under General Notices and Requirements.]

Labeling—Label it to indicate the name of the plant part used for preparation; the name of the solvent or solvent mixture used for extraction; and the content of the constituents of interest and the ratio of starting material to final product.

Auxiliary Information—Please [check for your question in the FAQs](#) before contacting USP.

### 571 VITAMIN A ASSAY

#### CHEMICAL METHOD

The following procedure is provided for the determination of vitamin A as an ingredient of Pharmacopeial preparations. It conforms to that which was adopted in 1956 for international use by the International Union of Pure and Applied Chemistry.

Complete the assay promptly, and exercise care throughout the procedure to keep to a minimum the exposure to actinic light and to atmospheric oxygen and other oxidizing agents, preferably by the use of low-actinic glassware and an atmosphere of an inert gas.

##### Special Reagents—

ether—Use ethyl ether, and use it within 24 hours after opening the container.

isopropyl alcohol—Use spectrophotometric-grade isopropyl alcohol (see Isopropyl Alcohol under Reagent Specifications in the section [Reagents, Indicators, and Solutions](#)).

Procedure—Accurately weigh, count, or measure a portion of the test specimen expected to contain the equivalent of not less than 0.15 mg of retinol but containing not more than 1 g of fat. If in the form of capsules, tablets, or other solid, so that it cannot be saponified efficiently by the ensuing instructions, reflux the portion taken in 10 mL of water on a steam bath for about 10 minutes, crush the remaining solid with a blunt glass rod, and warm for about 5 minutes longer.

Transfer to a suitable borosilicate glass flask, and add 30 mL of alcohol, followed by 3 mL of potassium hydroxide solution (9 in 10). Reflux in an all-borosilicate glass apparatus for 30 minutes. Cool the solution, add 30 mL of water, and transfer to a conical separator. Add 4 g of finely powdered sodium sulfate decahydrate. Extract by shaking with one 150-mL portion of ether for 2 minutes, and then, if an emulsion forms, with three 25-mL portions of ether. Combine the ether extracts, if necessary, and wash by swirling gently with 50 mL of water.

Repeat the washing more vigorously with three additional 50-mL portions of water. Transfer the washed ether extract to a 250-mL volumetric flask, add ether to volume, and mix.

Evaporate a 25.0-mL portion of the ether extract to about 5 mL. Without applying heat and with the aid of a stream of inert gas or vacuum, continue the evaporation to about 3 mL. Dissolve the residue in sufficient isopropyl alcohol to give an expected concentration of the equivalent of 3 µg to 5 µg of vitamin A per mL or to give an absorbance in the range 0.5 to 0.8 at 325 nm. Determine the absorbances of the resulting solution at the wavelengths 310 nm, 325 nm, and 334 nm, with a suitable spectrophotometer fitted with matched quartz cells, using isopropyl alcohol as the blank.

when tocopherol is present—Transfer to a suitable borosilicate glass flask a test specimen, accurately measured, or not less than 5 previously crushed capsules or tablets. Reflux in an all-borosilicate glass apparatus with 30 mL of alcohol and 3 mL of potassium hydroxide solution (9 in 10) for 30 minutes. Add through the condenser 2.0 g of citric acid monohydrate, washing the walls of the condenser with 10 mL of water. Cool, and transfer the solution to a conical separator with the aid of 20 mL of water. Add 4 g of finely powdered sodium sulfate decahydrate. Extract with one 150-mL portion of ether and then, if an emulsion forms, with three 25-mL portions of ether. Combine the ether extracts, if necessary, and wash by swirling gently with 50 mL of water. Repeat the washing more vigorously with three additional 50-mL portions of water. Transfer the washed ether extract to a 250-mL volumetric flask, add ether to volume, and mix.

Evaporate a 50.0-mL aliquot of the ether solution of the unsaponifiable extract to about 5 mL. Without applying heat and with the aid of a stream of inert gas or vacuum, remove the residual ether. Dissolve the residue in 50.0 mL of isopropyl alcohol.

Hydrogenated Portion—Pipet 15.0 mL of the isopropyl alcohol solution into a 50-mL centrifuge tube, add approximately 200 mg of palladium catalyst, stir with a glass rod, and hydrogenate for 10 minutes in a Hydrogenator such as is described in the [Alpha Tocopherol Assay](#) (551), using isopropyl alcohol in the blank tube. Add about 300 mg of chromatographic siliceous earth, stir with a glass rod, and immediately centrifuge until the solution is clear.

Test a 1-mL aliquot of the solution by removing the solvent by evaporation, dissolving the residue in 1 mL of chloroform, and adding 10 mL of [phosphomolybdic acid TS](#): no detectable blue-green color appears. [note—If a blue-green color appears, repeat the hydrogenation for a longer time period, or with a new lot of catalyst.]

Into two separate flasks pipet equal volumes of the Hydrogenated Portion and the untreated isopropyl alcohol solution, respectively, and add sufficient isopropyl alcohol to give an expected concentration of vitamin A equivalent to 3 µg to 5 µg per mL. Determine the absorbances of the untreated solution against the solution from the Hydrogenated Portion as a blank, at the wavelengths 310 nm, 325 nm, and 334 nm, with a suitable spectrophotometer fitted with matched quartz cells.

Calculation—Calculate the vitamin A content as follows:

$$\text{Content (in mg)} = 0.549A325 / LC$$

in which A325 is the observed absorbance at 325 nm; L is the length, in cm, of the absorption cell; and C is the amount of test specimen expressed as g, capsule, or tablet in each 100 mL of the final isopropyl alcohol solution, provided that A325 has a value not less than [A325]/1.030 and not more than [A325]/0.970, where [A325] is the corrected absorbance at 325 nm and is given by the equation:

$$[A325] = 6.815A325 - 2.555A310 - 4.260A334$$

in which A designates the absorbance at the wavelength indicated by the subscript.

Where [A325] has a value less than A325/1.030, apply the following equation:

$$\text{Content (in mg)} = 0.549[A325] / LC$$

in which the values are as defined herein. Each mg of vitamin A (alcohol) represents 3333 USP Units of vitamin A.

Confidence Interval—The range of the limits of error, indicating the extent of discrepancy to be expected in the results of different laboratories at P = 0.05, is approximately  $\pm 8\%$ .

#### CHROMATOGRAPHIC METHOD

The following pressurized liquid chromatographic procedure is provided for the determination of Vitamin A. Where the use of vitamin A ester (retinyl acetate or retinyl palmitate) is specified in the following procedure, use the chemical form present in the raw material. Use low-actinic glassware throughout this procedure.

[USP Reference Standards](#) (11)—[note—Use [USP Vitamin A RS](#), all-trans retinyl acetate, for assaying pharmaceutical dosage forms that are labeled to contain retinol or vitamin A ester (retinyl acetate or retinyl palmitate).]

Mobile Phase—Use n-hexane.

System Suitability Preparation— Dissolve an accurately weighed quantity of retinyl palmitate and [USP Vitamin A RS](#) in n-hexane to obtain a solution containing about 7.5 µg per mL each.

Standard Preparation— Dissolve an accurately weighed quantity of [USP Vitamin A RS](#) in n-hexane, and dilute quantitatively, and stepwise if necessary, to obtain a solution having a known concentration of about 15 µg of retinyl acetate per mL.

Assay Preparation— Transfer about 15 mg of vitamin A ester (retinyl acetate or retinyl palmitate), accurately weighed, to a 100-mL volumetric flask, dissolve in and dilute with n-hexane to volume, and mix. Pipet 5.0 mL of this solution into a 50-mL volumetric flask, dilute with n-hexane to volume, and mix.

Chromatographic System (see [Chromatography \(621\)](#))—The liquid chromatograph is equipped with a 325-nm detector and a 4.6-mm × 15-cm column that contains packing L8. The flow rate is about 1 mL per minute. Chromatograph the System Suitability Preparation, and record the peak responses as directed for Procedure: the resolution, R, between retinyl acetate and retinyl palmitate is not less than 10; and the relative standard deviation for replicate injections is not more than 3.0%.

Procedure— Separately inject equal volumes (about 40 µL) of the Standard Preparation and the Assay Preparation into the chromatograph, record the chromatograms, and measure the responses for retinyl acetate obtained from the Standard Preparation and the peak area for retinyl acetate or retinyl palmitate in the chromatogram of the Assay Preparation.

Calculate the quantity, in mg, of vitamin A as the retinol equivalent (C<sub>20</sub>H<sub>30</sub>O) in the portion of vitamin A taken by the formula:

$$0.872CD(rU / rS)$$

in which 0.872 is the factor used to convert retinyl acetate, obtained from [USP Vitamin A RS](#), to its retinol equivalent; C is the concentration, in mg per mL, of [USP Vitamin A RS](#) in the Standard Preparation; D is the dilution factor, in mL, for the Assay Preparation; and rU and rS are the peak responses of the retinyl ester obtained from the Assay Preparation and the Standard Preparation, respectively. [note—The molar responses of retinyl acetate and retinyl palmitate are equivalent.]

Auxiliary Information— Please [check for your question in the FAQs](#) before contacting USP.

### 581 VITAMIN D ASSAY

#### Chromatographic Method

The following pressurized liquid chromatographic procedure is provided for the determination of vitamin D, as cholecalciferol or as ergocalciferol, as an ingredient of Pharmacopeial multiple-vitamin preparations.

Throughout this assay, protect solutions containing, and derived from, the test specimen and the Reference Standard from the atmosphere and light, preferably by the use of a blanket of inert gas and low-actinic glassware.

USP Reference Standards (11)—[note—Use [USP Ergocalciferol RS](#), or [USP Cholecalciferol RS](#), for assaying pharmaceutical dosage forms that are labeled to contain vitamin D as ergocalciferol, or as cholecalciferol, respectively.] USP Cholecalciferol RS. [USP A<sub>4,6</sub>-Cholestadienol RS](#). [USP Ergocalciferol RS](#). [USP Vitamin D Assay System Suitability RS](#).

#### Special Reagents and Solutions—

Ether— Use ethyl ether. Use within 24 hours after opening container.

Dehydrated Hexane— Prepare a chromatographic column by packing a chromatographic tube, 60 cm × 8 cm in diameter, with 500 g of 50- to 250-µm chromatographic siliceous earth, activated by drying at 150° for 4 hours (see Column Adsorption Chromatography under [Chromatography \(621\)](#)). Pass 500 mL of hexanes through the column, and collect the eluate in a glass-stoppered flask.

Butylated Hydroxytoluene Solution— Dissolve a quantity of butylated hydroxytoluene in chromatographic hexane to obtain a solution containing 10 mg per mL.

Aqueous Potassium Hydroxide Solution— Dissolve 500 g of potassium hydroxide in 500 mL of freshly boiled water, mix, and cool. Prepare this solution fresh daily.

Alcoholic Potassium Hydroxide Solution— Dissolve 3 g of potassium hydroxide in 50 mL of freshly boiled water, add 10 mL of alcohol, dilute with freshly boiled water to 100 mL, and mix. Prepare this solution fresh daily.

Sodium Ascorbate Solution— Dissolve 3.5 g of ascorbic acid in 20 mL of 1 N sodium hydroxide. Prepare this solution fresh daily.

Sodium Sulfide Solution— Dissolve 12 g of sodium sulfide in 20 mL of water, dilute with glycerin to 100 mL, and mix.

Mobile Phase A— Prepare a mixture of acetonitrile, methanol, and water (25:25:1). The amount of water and the flow rate may be varied to meet system suitability requirements.

Mobile Phase B— Prepare a 3 in 1000 mixture of n-amyl alcohol in Dehydrated Hexane. The ratio of components and the flow rate may be varied to meet system suitability requirements.

Internal Standard Solution— Transfer 15 mg of [USP A<sub>4,6</sub>-Cholestadienol RS](#), accurately weighed, to a 200-mL volumetric flask, add a 1 in 10 mixture of toluene and Mobile Phase B to volume, and mix.

Standard Preparation— Transfer about 25 mg of [USP Ergocalciferol RS](#) or [Cholecalciferol RS](#), accurately weighed, to a 50-mL volumetric flask, dissolve without heat in toluene, add toluene to volume, and mix. Pipet 10 mL of this stock solution into a 100-mL volumetric flask, dilute with toluene to volume, and mix. Prepare stock solution fresh daily.

#### Assay Preparation—

For oily solutions— Accurately weigh a portion of the specimen to be assayed, preferably more than 0.5 g and equivalent to about 125 µg of cholecalciferol or ergocalciferol (5000 USP Units). Add 1 mL of Sodium Ascorbate Solution, 25 mL of alcohol, and 2 mL of Aqueous Potassium Hydroxide Solution, and mix.

For capsules or tablets— Reflux not less than 10 capsules or tablets with a mixture of 10 mL of Sodium Ascorbate Solution and 2 drops of Sodium Sulfide Solution on a steam bath for 10 minutes, crush any remaining solids with a blunt glass rod, and continue heating for 5 minutes. Cool, add 25 mL of alcohol and 3 mL of Aqueous Potassium Hydroxide Solution, and mix.

For dry preparations and aqueous dispersions— Accurately weigh a portion of the specimen to be assayed, preferably more than 0.5 g and equivalent to about 125 µg of cholecalciferol or ergocalciferol (5000 USP Units). Add, in small quantities and with gentle swirling, 25 mL of alcohol, 5 mL of Sodium Ascorbate Solution, and 3 mL of Aqueous Potassium Hydroxide Solution.

Saponification and extraction— Reflux the mixture prepared from the specimen to be assayed on a steam bath for 30 minutes. Cool rapidly under running water, and transfer the saponified mixture to a conical separator, rinsing the saponification flask with two 15-mL portions of water, 10 mL of alcohol, and two 50-mL portions of ether. Shake the combined saponified mixture and rinsings vigorously for 30 seconds, and allow to stand until both layers are clear. Transfer the aqueous phase to a second conical separator, add a mixture of 10

of alcohol and 50 mL of solvent hexane, and shake vigorously. Allow to separate, transfer the aqueous phase to a third conical separator, and transfer the hexane phase to the second separator, rinsing the second separator with two 10-mL portions of solvent hexane, adding the rinsings to the first separator. Shake the aqueous phase in the third separator with 50 mL of solvent hexane, and add the hexane phase to the first separator. Wash the combined ether-hexane extracts by shaking vigorously with three 50-mL portions of Alcoholic Potassium Hydroxide Solution, and wash with 50-mL portions of water vigorously until the last washing is neutral to phenolphthalein. Drain any remaining drops of water from the combined ether-hexane extracts, add 2 sheets of 9-cm filter paper, in strips, to the separator, and shake. Transfer the washed ether-hexane extracts to a round-bottom flask, rinsing the separator and paper with solvent hexane. Combine the hexane rinsings with the ether-hexane extracts, add 5.0 mL of Internal Standard Solution and 100  $\mu$ L of Butylated Hydroxytoluene Solution, and mix. Evaporate to dryness in vacuum by swirling in a water bath maintained at a temperature not higher than 40°. Cool under running water, and introduce nitrogen sufficient to restore atmospheric pressure. Without delay, dissolve the residue in 5.0 mL of a mixture of equal volumes of acetonitrile and methanol, or in a measured portion of the acetonitrile-methanol mixture until the concentration of vitamin D is about 25  $\mu$ g per mL, to obtain the Assay Preparation.

Chromatographic System— Use a chromatograph, operated at room temperature, fitted with an UV detector that monitors absorption at 254 nm, a 30-cm  $\times$  4.6-mm stainless steel cleanup column packed with column packing L7 and using Mobile Phase A, and a 25-cm  $\times$  4.6-mm stainless steel analytical column packed with column packing L3 and using Mobile Phase B.

Cleanup Column System Suitability Test— Pipet 5 mL of the Standard Preparation into a round-bottom flask fitted with a reflux condenser, and add 2 or 3 crystals of butylated hydroxytoluene. Displace the air with nitrogen, and heat in a water bath maintained at a temperature of 90° in subdued light under an atmosphere of nitrogen for 45 minutes, to obtain a solution containing vitamin D and pre-vitamin D. Cool, add 10.0 mL of Internal Standard Solution, mix, and evaporate in vacuum to dryness by swirling in a water bath maintained at a temperature not higher than 40°. Cool under running water, and introduce nitrogen sufficient to restore atmospheric pressure. Without delay, dissolve the residue in 10.0 mL of a mixture of equal volumes of acetonitrile and methanol, and mix. Inject 500  $\mu$ L of this solution into the cleanup column, and record the chromatogram as directed under Procedure. The chromatogram exhibits a peak exhibiting a retention time between 5 and 9 minutes, corresponding to the separation under a single peak of the mixture of vitamin D, pre-vitamin D, and  $\Delta$ 4,6-cholestadienol from other substances. Adjust the water content or other operating parameters, if necessary (see Mobile Phase A).

Analytical Column System Suitability Test— Transfer about 100 mg of USP Vitamin D Assay System Suitability RS to a 100-mL volumetric flask, add a 1 in 20 mixture of toluene and Mobile Phase B to volume, and mix. Heat a portion of this solution, under reflux, at 90° for 45 minutes, and cool. Chromatograph five injections of the resulting solution, and measure the peak responses as directed for Procedure: the resolution, R, between trans-cholecalciferol and pre-cholecalciferol is not less than 1.0, and the relative standard deviation for the cholecalciferol peak response does not exceed 2.0%. [note—Chromatograms obtained as directed for this test exhibit relative retention times of approximately 0.4 for pre-cholecalciferol, 0.5 for trans-cholecalciferol, and 1.0 for cholecalciferol.]

#### Calibration—

Vitamin D Response Factor— Transfer 4.0 mL of the Standard Preparation and 10.0 mL of Internal Standard Solution to a 100-mL volumetric flask, dilute with Mobile Phase B to volume, and mix to obtain the Working Standard Preparation. Store this Working Standard Preparation at a temperature not above 0°, retaining the unused portion for the Procedure. Inject 200  $\mu$ L of the Working Standard Preparation into the analytical column, and measure the peak responses for vitamin D and for  $\Delta$ 4,6-cholestadienol. The relative retention time of  $\Delta$ 4,6-cholestadienol is about 1.3. Calculate the response factor, FD, by the formula:

$$FD = \frac{CS}{R'S}$$

in which CS and CR are the concentrations, in  $\mu$ g per mL, of vitamin D and  $\Delta$ 4,6-cholestadienol, respectively, in the Working Standard Preparation, and RS is the ratio of the peak response of vitamin D to that of  $\Delta$ 4,6-cholestadienol.

Pre-Vitamin D Response Factor— Pipet 4 mL of the Standard Preparation into a round-bottom flask fitted with a reflux condenser, and add 2 or 3 crystals of butylated hydroxytoluene. Displace the air with nitrogen, and heat in a water bath maintained at a temperature of 90° in subdued light under a nitrogen atmosphere for 45 minutes, to obtain a solution containing vitamin D and pre-vitamin D. Cool, transfer with the aid of several portions of Mobile Phase B to a 100-mL volumetric flask containing 10.0 mL of Internal Standard Solution, dilute with Mobile Phase B to volume, and mix to obtain the Working Mixture. Inject 200  $\mu$ L of this Working Mixture into the analytical column, and measure the peak responses for vitamin D, pre-vitamin D, and  $\Delta$ 4,6-cholestadienol. Calculate the concentration, C's, in  $\mu$ g per mL, of vitamin D in the (heated) Working Mixture by the formula:

$$FD \times CS = C'D$$

in which CR is the concentration, in  $\mu$ g per mL, of  $\Delta$ 4,6-cholestadienol, and R'S is the ratio of the peak response for vitamin D to that for  $\Delta$ 4,6-cholestadienol. Calculate the concentration, C'PRE, in  $\mu$ g per mL, of pre-vitamin D, in the Working Mixture by the formula:

$$C'PRE = CS - C'D$$

Calculate the response factor, FPRE, for pre-vitamin D by the formula:

$$(FD \times CS) / (C'PRE)$$

in which R'PRE is the ratio of the peak response of pre-vitamin D to that of  $\Delta$ 4,6-cholestadienol. [note—Value of FPRE determined in duplicate, on different days, can be used during the whole procedure.]

Procedure— Inject 500  $\mu$ L of the Assay Preparation into the cleanup column, and collect the fraction representing 0.7 to 1.3 relative to the retention time of the mixed vitamin D peak (see Cleanup Column System Suitability Test) in a round-bottom flask. Add 50  $\mu$ L of Butylated Hydroxytoluene Solution, mix, and evaporate in vacuum to dryness by swirling in a water bath maintained at a temperature not higher than 40°. Cool under running water, and introduce nitrogen sufficient to restore atmospheric pressure. Without delay, dissolve the residue in 5.0 mL of a 1 in 20 mixture of toluene and Mobile Phase B, and mix. Inject 200  $\mu$ L of this solution into the analytical column, and measure the peak responses for vitamin D, pre-vitamin D, and  $\Delta$ 4,6-cholestadienol. Calculate the concentration, in  $\mu$ g per mL, of cholecalciferol (C27H44O) or ergocalciferol (C28H44O) in the Assay Preparation by the formula:

$$(R'DF + R'PRE)C'D$$

in which R'D is the ratio of the peak response of vitamin D to that of  $\Delta$ 4,6-cholestadienol; R'PRE is the ratio of the peak response of pre-vitamin D to that of  $\Delta$ 4,6-cholestadienol; and C'D is the concentration, in  $\mu$ g per mL, of  $\Delta$ 4,6-cholestadienol in the Assay Preparation.

#### Chemical Method

The following procedure is provided for the determination of vitamin D as an ingredient of Pharmacopeial preparations.

Complete the assay promptly, and exercise care throughout the procedure to keep to a minimum the exposure to air and to actinic light, preferably by the use of a blanket of inert gas and low-actinic glassware.

USP Reference Standards [11]—[note—Use USP Ergocalciferol RS, or USP Cholecalciferol RS, for assaying pharmaceutical dosage forms that are labeled to contain vitamin D as ergocalciferol, or as cholecalciferol, respectively.] USP Cholecalciferol RS, USP Ergocalciferol RS.

#### Special Reagents and Solutions—

Chromatographic Fuller's Earth— Use chromatographic Fuller's earth having a water content corresponding to between 8.5% and 9.0% of loss on drying.

Solvent Hexane— Use solvent hexane (see under Reagents, Indicators, and Solutions), redistilling if necessary so that it meets the following additional specification:

spectral purity—Measure in a 1-cm cell at 300 nm, with a suitable spectrophotometer, against air as the blank: the absorbance is not more than 0.070.

Ethylene Dichloride— Purify by passage through a column of granular (20 to 200 mesh) silica gel.

Potassium Hydroxide Solution— Dissolve 500 g of potassium hydroxide in water to make 1000 mL.

Butylated Hydroxytoluene Solution— Dissolve 10 mg of butylated hydroxytoluene in 100 mL of alcohol. Prepare this solution fresh daily.

Ether— Use freshly distilled ether, discarding the first and last 10% portions of the distillate.

Color Reagent— Prepare two stock solutions as follows.

solution a—Empty, without weighing, the entire contents of a previously unopened 113-g bottle of dry, crystalline antimony trichloride into a flask containing about 400 mL of Ethylene Dichloride. Add about 2 g of anhydrous alumina, mix, and pass through filter paper into a clear-glass, glass-stoppered container calibrated at 500 mL. Dilute with Ethylene Dichloride to 500 mL, and mix: the absorbance of the solution, measured in a 20-mm cell at 500 nm, with a suitable spectrophotometer, against Ethylene Dichloride, does not exceed 0.070.

solution b—Mix, under a hood, 100 mL of acetyl chloride and 400 mL of Ethylene Dichloride.

Mix 45 mL of Solution A and 5 mL of Solution B to obtain the Color Reagent. Store in a tight container, and use within 7 days, but discard any reagent in which a color develops.

Chromatographic Tubes—

First Column— Arrange for descending column chromatography a tube of 2.5-cm (inside) diameter, about 25 cm long, and constricted to 8-mm diameter for a distance of 5 cm at the lower end, by inserting at the point of constriction a coarse-porosity, sintered-glass disk or a small plug of glass wool. The constricted portion may be fitted with an inert, plastic stopcock.

Second Column— Select a tube that is made up of three sections: (1) a flared top section, 18 mm in (inside) diameter and approximately 14 cm long, (2) a middle section, 6 mm in (inside) diameter and approximately 25 cm long, and (3) a tapered, constricted lower exit tube approximately 5 cm long. Insert a small plug of glass wool in the upper 1-cm portion of the constricted section.

Chromatographic Columns—

First Column— To about 125 mL of isooctane contained in a screw-capped, wide-mouth bottle add 25 g of chromatographic siliceous earth, and shake until a slurry is formed. Add, dropwise and with vigorous mixing, 10 mL of polyethylene glycol 600. Replace the bottle cover, and shake vigorously for 2 minutes. Pour about half of the resulting slurry into the chromatographic tube, and allow it to settle by gravity. Then apply gentle suction, and add the remainder of the slurry in small portions, packing each portion with a 20-mm disk plunger. When a solid surface has formed, remove the vacuum, and add about 2 mL of isooctane.

Second Column— Pack the midsection of the tube with 3 g of moderately coarse Chromatographic Fuller's Earth with the aid of gentle suction (about 125 mm of mercury).

Standard Preparation— Dissolve about 25 mg of Reference Standard, accurately weighed, in isooctane to give a known concentration of about 250  $\mu$ g per mL. Store in a refrigerator.

On the day of assay, pipet 1 mL of this solution into a 50-mL volumetric flask, remove the solvent with a stream of nitrogen, and dissolve the residue in and dilute with Ethylene Dichloride to volume, and mix.

Sample Preparation— Accurately weigh or measure a portion of the sample to be assayed, equivalent to not less than 125  $\mu$ g but preferably about 250  $\mu$ g of ergocalciferol (10,000 USP Units). If little or no vitamin A is present in the sample, add about 1.5 mg (the equivalent of 3000 USP Units) of vitamin A acetate to provide the needed pilot bands in the subsequent chromatography.

For capsules or tablets, reflux not fewer than 10 of them in 10 mL of water on a steam bath for about 10 minutes, crush the remaining solid with a blunt glass rod, and warm for 5 minutes longer.

Add a volume of Potassium Hydroxide Solution representing 2.5 mL for each g of the total weight of the sample, but not less than a total of 3.0 mL. Add 10 mL of Butylated Hydroxytoluene Solution and 20 mL of alcohol. Reflux vigorously on a steam bath for 30 minutes. Cool, and transfer the saponified mixture to a conical separator, rinsing the saponification flask with three 10-mL portions of water and three 50-mL portions of Ether, adding each rinse to the separator. Add about 4 g of sodium sulfate decahydrate to the separator, and extract by shaking for 2 minutes. If an emulsion forms, extract with three 25-mL portions of Ether. Combine the ether extracts, if necessary, and wash by swirling gently with 50 mL of water. Repeat the washing more vigorously with additional 50-mL portions of water until the last portion shows no pink color on the addition of *phenolphthalein* TS. Transfer the washed ether extract to a 250-mL volumetric flask, dilute with Ether to volume, and mix. Transfer the entire sample or an accurately measured aliquot containing about 250  $\mu$ g to a tall-form, 400-mL beaker containing about 5 g of anhydrous sodium sulfate. Stir for 2 minutes, then decant the solution into a second 400-mL beaker. Rinse the sodium sulfate with three 25-mL portions of Ether, adding each rinse to the main portion. Reduce the total volume to about 30 mL by evaporation on a steam bath, and transfer the concentrate to a small, round-bottom evaporation flask. Rinse the beaker with three 10-mL portions of Ether, adding the rinsings to the flask. With the aid of vacuum in a water bath at a temperature not exceeding 40°, or with a stream of nitrogen at room temperature, remove the remaining solvent completely. Dissolve the residue in a small amount of Solvent Hexane, transfer to a 10-mL volumetric flask, dilute with Solvent Hexane to volume, and mix to obtain the Sample Preparation.

Procedure—

First Column Chromatography— Just as the 2 mL of isooctane disappears into the surface of the prepared First Column, pipet 2 mL of the Sample Preparation onto the column. As the meniscus of the Sample Preparation reaches the column surface, add the first of three 2-mL portions of Solvent Hexane, adding each succeeding portion as the preceding portion disappears into the column. Continue adding Solvent Hexane in portions of 5 to 10 mL until 100 mL has been added. If necessary, adjust the flow rate to between 3 and 6 mL per minute, by application of gentle pressure at the top of the chromatographic tube.

Discard the first 20 mL of effluent, and collect the remainder. Examine the column under UV light at intervals during the chromatography, and stop the flow when the front of the fluorescent band representing vitamin A is about 5 mm from the bottom of the column. (The UV lamp should provide weak radiation in the 300-nm region. It is frequently necessary to use a narrow aperture or screen with commercial lamps to reduce the amount of radiation to the minimum required to visualize the vitamin A on the column.)

Transfer the eluate to a suitable evaporation flask, and remove the Solvent Hexane completely under vacuum at a temperature not higher than 40° or with a stream of nitrogen at room temperature. Dissolve the residue in about 10 mL of Solvent Hexane.

Second Column Chromatography— Add the solvent hexane solution obtained as directed under First Column Chromatography onto the Second Column. Rinse the evaporation flask with a total of 10 mL of Solvent Hexane in small portions, adding each portion to the Second Column and allowing it to flow through the column, and discard the effluent. When about 1 mL of the hexane remains above the surface of the column, add 75 mL of toluene, and elute with the aid of gentle suction (about 125 mm of mercury), collecting the eluate. Evaporate the toluene under vacuum at a temperature not higher than 40°, or with a stream of nitrogen at room temperature.

Assay Preparation— Dissolve the residue obtained as directed under Second Column Chromatography in a small amount of Ethylene Dichloride, transfer to a 10-mL volumetric flask, dilute with Ethylene Dichloride to volume, and mix to obtain the Assay Preparation.

Color Development— Into each of three suitable, matched colorimeter tubes of about 20-mm (inside) diameter, and designated tubes 1, 2, and 3, respectively, pipet 1 mL of the Assay Preparation. Into tube 1, pipet 1 mL of the Standard Preparation; into tube 2, 1 mL of Ethylene Dichloride; and into tube 3, 1 mL of a mixture of equal volumes of acetic anhydride and Ethylene Dichloride. To each tube add quickly, and preferably from an automatic pipet, 5.0 mL of Color Reagent, and mix. After 45 seconds, accurately timed, following the addition of the Color Reagent, determine the absorbances of the three solutions at 500 nm, with a suitable spectrophotometer, using Ethylene Dichloride as the blank. Similarly, 45 seconds after making the first reading on each solution, determine the absorbances of the solutions in tubes 2 and 3 at 550 nm, in a similar manner. Designate the absorbances as A1500, A2500, A3500, A2550, and A3550, respectively, in which the superscript indicates the number of the tube and the subscript, the wavelength.

Calculation— Calculate the quantity, in  $\mu$ g, of vitamin D in the portion of the sample taken by the formula:

$$(CS / C)(AU / AS)$$

in which CS is the concentration of vitamin D, in  $\mu$ g per mL, of the Standard Preparation; C is the concentration of the sample (as g, capsules, tablets, etc.) in each mL of the final solution; AU has the value of  $(A2500 - A3500) - 0.67(A2550 - A3550)$  determined from the absorbances observed on the solution from the Assay Preparation; and AS has the value of  $A1500 - A2500$  determined on the solutions from the Standard Preparation.

Biological Method

The biological assay of vitamin D comprises the recording and interpretation of observations on groups of rats maintained on specified dietary regimens throughout specified periods of their lives whereby the biological response to the preparation under assay is compared with the response to [USP Vitamin D Capsules RS](#).

USP Reference Standards (11) — USP Cholecalciferol RS.

Preliminary Period— Throughout the preliminary period in the life of a rat, which is not longer than 30 days and extends from birth to the first day of the depletion period, maintain litters of rats under the immediate supervision of, or according to the directions of, the individual responsible for the assay. During the preliminary period, use a dietary regimen that provides for normal development but is limited in its content of vitamin D, so that when placed upon the Rachitogenic Diet in the depletion period the rats develop rickets. At the end of the preliminary period, reject any rat that weighs less than 44 g or more than 60 g, or that shows evidence of injury, disease, or anatomical abnormality.

Depletion Period— Through the depletion period, which extends from the end of the preliminary period to the first day of the assay period, provide each rat ad libitum with the Rachitogenic Diet and water, and allow access to no other food or dietary supplement.

Rachitogenic Diet— The Rachitogenic Diet consists of a uniform mixture of the following ingredients in the proportions shown in the accompanying table.

Rachitogenic Diet	
Ingredient	Parts by weight
Whole yellow corn, ground	76
Wheat gluten, ground	20
Calcium carbonate	3
Sodium chloride	1

When a chemical analysis of the entire ration shows a Ca:P ratio of less than 4:1 or more than 5:1, the proportion of calcium carbonate may be varied to bring the adjusted ratio to a uniform level within this range.

Assigning Rats to Groups for Assay Period— Consider a litter suitable for the assay period when individual rats in the litter show evidence of rickets such as enlarged joints and a distinctive wobbly, rachitic gait, provided that the depletion period is not less than 19 or more than 25 days. The presence of rickets may be established also from the width of the rachitic metaphysis upon X-ray examination or by applying the Line Test (described below) to a leg bone of one member of each litter.

Record the weight of each rat, and assign it to a group, in which each rat will be fed a specified dose of the Reference Standard or of an assay sample that is under examination for its vitamin D potency. For each assay sample provide one or more assay groups and not less than two standard groups. The two standard groups may be used for the concurrent assay of more than one assay sample. Within an interval not exceeding 30 days, complete the assignment of rats to groups according to a design that divides litters among the groups, to achieve a complete balance.

For complete balance, whereby each litter is represented equally in every group, use 7 or more litters containing at least as many depleted rats as there are groups. From a given litter, assign one rat, selected at random, to each group on the same day. If a litter contains twice as many rats as there are groups, assign a second series of rats similarly. The last one or two litters to be assigned may be allotted to groups so that at the start of the assay period the average body weight of any completed groups will not differ by more than 8 g from that of any other group.

Assay Doses— Select two dosage levels of the USP Cholecalciferol RS, spaced so that the ratio of the larger to the smaller dose is not less than 1.5 or more than 2.5. Select one or two dosage levels based upon a single assumed potency for each sample. The dosage levels of the sample are equivalent to those of the standard or to a mid-level equal to the square root of the product of the two dosage levels of the standard.

Select dosage levels such that, when fed to rachitic rats, they are expected to produce degrees of calcification within the range specified under the test of data acceptability. Before feeding, the Reference Standard and/or sample may be diluted with cottonseed oil, provided that not more than 0.2 mL is fed on any one day. Store the oil solutions in well-closed bottles, protected from light, at a temperature not exceeding 10°, and use within 5 weeks.

Assign one group of rats to each dosage level of the standard and of the one or more samples.

Assay Period— During the assay period, which extends from the end of the depletion period for a fixed interval of 7 to 10 days, cage each rat individually and provide it ad libitum with the Rachitogenic Diet and water. Supply a Rachitogenic Diet prepared from the same lots of ingredients to all rats. On the first and on the third (or fourth) day of the assay period, feed each rat one-half of its total assigned dose.

Throughout the assay period, maintain as uniform environmental conditions as possible for all rats, and exclude exposure to antirachitic radiations. At the end of a fixed period of 7 to 10 days, weigh and kill each rat. From those rats that do not weigh less at the end than at the start of the assay period and that have consumed each assigned dose within 24 hours of the time it was fed, dissect out one or more leg bones for examination by the Line Test.

Line Test— Remove the proximal end of a tibia or the distal end of a radius, and clean adhering tissue from it, in any one assay using the same bone from all animals. With a clean, sharp blade cut a median, longitudinal section through the juncture of the epiphysis and diaphysis at the same place on each bone. Rinse both sections in purified water, immerse immediately in silver nitrate solution (1 in 50) for 1 minute, and rinse again in purified water. Expose the cut surface of bone, in water, to daylight or another source of actinic light until the calcified areas develop a clearly defined stain without marked discoloration of the uncalcified areas. The staining procedure may be modified to differentiate more clearly between calcified and uncalcified areas.

Score the degree of calcification of the rachitic metaphysis in each rat, according to a scale that allows the average response to be plotted as a straight line against the logarithm of the dose.

Acceptability— Observations are acceptable for use in calculation of the potency only from those groups in which two-thirds or more but not less than 7 rats show calcification at least as great as the lowest level and not greater than the highest level. If the average score of the standard group on the high dosage level is not greater than the average score of the standard group on the low dosage level, discard the results, and repeat the assay. If an assay sample is represented solely by assay groups that are not acceptable for measuring vitamin D potency and in each of which the average score is less than the average score of the standard group on the low dosage level or more than the average score of the standard group on the high dosage level, its assayed content of vitamin D is respectively less than that represented by the low dose or more than that represented by the high dose of the Reference Standard.

Calculation— Tabulate the scores (y), listing each litter in a separate row with treatment groups in columns. Omit any groups that do not meet the test for Acceptability. Equalize the number of observations in the acceptable groups by disregarding the results on all litters not equally represented in the groups or by other suitable means (see Design and Analysis of Biological Assays (111)). Total the f scores for each of the treatment groups, where f is the number of litters, and designate each total as T with subscripts 1 and 2 for the low and high dosage levels, respectively. Compute the slope b from the sums of T<sub>1</sub>, i.e.,  $\Sigma T_1$ , and of T<sub>2</sub>, i.e.,  $\Sigma T_2$ , for the standard and sample, provided the latter is represented at both dosage levels, from the equation:

$$b = (\Sigma T_2 - \Sigma T_1) / ih'$$

in which i is the logarithm of the ratio of the high dose to the low dose and is the same for each preparation, and h' is the number of preparations represented by two dosage levels and included in the calculation of the value of b.

Compute the logarithm of the relative potency of each specimen under assay from the equation:

$$\begin{aligned} \log (\text{relative potency}) &= M' \\ &= (y_u - \bar{y}_s)/b \\ &= ih'T/2\Sigma T_b \end{aligned}$$

in which each mean score, y<sub>u</sub> for the assay sample and y<sub>s</sub> for the Reference Standard, is the average of the individual scores for an intermediate dosage level or of the two means for

the high and the low dosage levels and where  $T_b = \Sigma T_2 - \Sigma T_1$  and  $T_a$  is as defined (see [Design and Analysis of Biological Assays](#) (111)). Convert each observed  $M'$  to its antilogarithm to obtain the relative potency of the sample. Multiply the relative potency by the assumed potency of the assay oil in Units per g, adopted at the start of the assay, to obtain its assayed content of vitamin D in USP Units per g.

Auxiliary Information— Please [check for your question in the FAQs](#) before contacting USP.

### 591 ZINC DETERMINATION

The need for a quantitative determination of zinc in the Pharmacopeial insulin preparations reflects the fact that the element is an essential component of zinc-insulin crystals. In common with lead, zinc may be determined either by the dithizone method or by atomic absorption.

#### Dithizone Method

Select all reagents for this test to have as low a content of heavy metals as practicable. If necessary, distill water and other solvents into hard or borosilicate glass apparatus. Rinse thoroughly all glassware with warm dilute nitric acid (1 in 2) followed by water. Avoid using on the separator any lubricants that dissolve in chloroform.

#### Special Solutions and Solvents—

ALKALINE AMMONIUM CITRATE SOLUTION— Dissolve 50 g of dibasic ammonium citrate in water to make 100 mL. Add 100 mL of ammonium hydroxide. Remove any heavy metals that may be present by extracting the solution with 20-mL portions of Dithizone Extraction Solution (see [Lead](#) (251)) until the dithizone solution retains a clear green color, then extract any dithizone remaining in the citrate solution by shaking with chloroform.

CHLOROFORM— Distill chloroform in hard or borosilicate glass apparatus, receiving the distillate in sufficient dehydrated alcohol to make the final concentration 1 mL of alcohol for each 100 mL of distillate.

DITHIZONE SOLUTION— Use Standard Dithizone Solution (see [Lead](#) (251)), prepared with the distilled Chloroform.

STANDARD ZINC SOLUTION— Dissolve 625 mg of zinc oxide, accurately weighed, and previously gently ignited to constant weight, in 10 mL of nitric acid, and add water to make 500.0 mL. This solution contains 1.0 mg of zinc per mL.

DILUTED STANDARD ZINC SOLUTION— Dilute 1 mL of Standard Zinc Solution, accurately measured, with 2 drops of nitric acid and sufficient water to make 100.0 mL. This solution contains 10  $\mu$ g of zinc per mL. Use this solution within 2 weeks.

TRICHLOROACETIC ACID SOLUTION— Dissolve 100 g of trichloroacetic acid in water to make 1000 mL.

Procedure— Transfer 1 to 5 mL of the preparation to be tested, accurately measured, to a centrifuge tube graduated at 40 mL. If necessary, add 0.25 N hydrochloric acid, dropwise, to obtain a clear solution. Add 5 mL of Trichloroacetic Acid Solution and sufficient water to make 40.0 mL. Mix, and centrifuge.

Transfer to a hard-glass separator an accurately measured volume of the supernatant believed to contain from 5 to 20  $\mu$ g of zinc, and add water to make about 20 mL. Add 1.5 mL of Alkaline Ammonium Citrate Solution and 35 mL of Dithizone Solution. Shake vigorously 100 times. Allow the chloroform phase to separate. Insert a cotton plug in the stem of the separator to remove any water emulsified with the chloroform. Collect the chloroform extract (discarding the first portion that comes through) in a test tube, and determine the absorbance at 530 nm, with a suitable spectrophotometer.

Calculate the amount of zinc present by reference to a standard absorbance-concentration curve obtained by using 0.5 mL, 1.0 mL, 1.5 mL, and, if the zinc content of the sample extracted exceeds 15  $\mu$ g, 2.0 mL of the Diluted Standard Zinc Solution, corrected as indicated by a blank determination run concomitantly, using all of the reagents but no added zinc.

Auxiliary Information— Please [check for your question in the FAQs](#) before contacting USP.

### 601 AEROSOLS, NASAL SPRAYS, METERED-DOSE INHALERS, AND DRY POWDER INHALERS

This general chapter contains test methods for propellants, pressurized topical aerosols, nasal sprays, metered-dose inhalers, and propellant-free dry powder inhalers used to aerosolize, or to aerosolize and meter, doses of powders for inhalation. Apply these methods, where indicated, in the testing of the appropriate dosage forms.

#### PROPELLANTS

Caution—Hydrocarbon propellants are highly flammable and explosive. Observe precautions and perform sampling and analytical operations in a well-ventilated fume hood. General Sampling Procedure

This procedure is used to obtain test specimens for those propellants that occur as gases at about 25° and that are stored in pressurized cylinders. Use a stainless steel sample cylinder equipped with a stainless steel valve and having a capacity of not less than 200 mL and a pressure rating of 240 psi or more. Dry the cylinder with the valve open at 110° for 2 hours, and evacuate the hot cylinder to less than 1 mm of mercury. Close the valve, cool, and weigh. Connect one end of a charging line tightly to the propellant container and the other end loosely to the sample cylinder. Carefully open the propellant container, and allow the propellant to flush out the charging line through the loose connection. Avoid excessive flushing, which causes moisture to freeze in the charging line and connections. Tighten the fitting on the sample cylinder, and open the sample cylinder valve, allowing the propellant to flow into the evacuated cylinder. Continue sampling until the desired amount of specimen is obtained, then close the propellant container valve, and finally close the sample cylinder valve. [Caution—Do not overload the sample cylinder; hydraulic expansion due to temperature change can cause overloaded cylinders to explode.] Again weigh the charged sample cylinder, and calculate the weight of the specimen.

#### Approximate Boiling Temperature

Transfer a 100-mL specimen to a tared, pear-shaped, 100-mL centrifuge tube containing a few boiling stones, and weigh. Suspend a thermometer in the liquid, and place the tube in a medium maintained at a temperature of 32° above the expected boiling temperature. When the thermometer reading becomes constant, record as the boiling temperature the thermometer reading after at least 5% of the specimen has distilled. Retain the remainder of the specimen for the determination of High-Boiling Residues.

High-Boiling Residues, Method I

Allow 85 mL of the specimen to distill as directed in the test for Approximate Boiling Temperature, and transfer the centrifuge tube containing the remaining 15 mL of specimen to a medium maintained at a temperature  $10^{\circ}$  above the boiling temperature. After 30 minutes, remove the tube from the water bath, blot dry, and weigh. Calculate the weight of the residue.

#### High-Boiling Residues, Method II

Prepare a cooling coil from copper tubing (about 6 mm outside diameter  $\times$  about 6.1 m long) to fit into a vacuum-jacketed flask. Immerse the cooling coil in a mixture of dry ice and acetone in a vacuum-jacketed flask, and connect one end of the tubing to the propellant sample cylinder. Carefully open the sample cylinder valve, flush the cooling coil with about 50 mL of the propellant, and discard this portion of liquefied propellant. Continue delivering liquefied propellant from the cooling coil, and collect it in a previously chilled 1000-mL sedimentation cone until the cone is filled to the 1000-mL mark. Allow the propellant to evaporate, using a warm water bath maintained at about  $40^{\circ}$  to reduce evaporating time. When all of the liquid has evaporated, rinse the sedimentation cone with two 50-mL portions of pentane, and combine the rinsings in a tared 150-mL evaporating dish. Transfer 100 mL of the pentane solvent to a second tared 150-mL evaporating dish, place both evaporating dishes on a water bath, evaporate to dryness, and heat the dishes in an oven at  $100^{\circ}$  for 60 minutes. Cool the dishes in a desiccator, and weigh. Repeat the heating for 15-minute periods until successive weighings are within 0.1 mg, and calculate the weight of the residue obtained from the propellant as the difference between the weights of the residues in the two evaporating dishes.

#### Water Content

Proceed as directed under [Water Determination \(921\)](#), with the following modifications: (a) Provide the closed-system titrating vessel with an opening through which passes a coarse-porosity gas dispersion tube connected to a sampling cylinder. (b) Dilute the Reagent with anhydrous methanol to give a water equivalence factor of between 0.2 and 1.0 mg per mL; age this diluted solution for not less than 16 hours before standardization. (c) Obtain a 100-g specimen as directed under General Sampling Procedure, and introduce the specimen into the titration vessel through the gas dispersion tube at a rate of about 100 mL of gas per minute; if necessary, heat the sample cylinder gently to maintain this flow rate.

#### Other Determinations

For those aerosols that use propellants, perform the tests specified in the individual NF propellant monographs.

### AEROSOLS

Because leaching of extractable substances into pressurized formulations should be minimized, valve materials and other components that are in contact with the product meet the requirements under [Elastomeric Closures for Injections \(381\)](#) (Note that under Physicochemical Test Procedures in (381) the directions for preparing a sample require pre-extraction, which may cause an underestimate of the amount of extractables from a given component.) See also Aerosols under [Pharmaceutical Dosage Forms \(1151\)](#).

#### TOPICAL AEROSOLS

The following tests are applicable to topical aerosols containing drug, in suspension or solution, packaged under pressure, and released upon activation of an appropriate valve system.

##### Delivery Rate and Delivered Amount

Perform these tests only on containers fitted with continuous valves.

**Delivery Rate**— Select not fewer than four aerosol containers, shake, if the label includes this directive, remove the caps and covers, and actuate each valve for 2 to 3 seconds. Weigh each container accurately, and immerse in a constant-temperature bath until the internal pressure is equilibrated at a temperature of  $25^{\circ}$  as determined by constancy of internal pressure, as directed under the Pressure Test below. Remove the containers from the bath, remove excess moisture by blotting with a paper towel, shake, if the label includes this directive, actuate each valve for 5.0 seconds (accurately timed by use of a stopwatch), and weigh each container again. Return the containers to the constant-temperature bath, and repeat the foregoing procedure three times for each container. Calculate the average Delivery Rate, in g per second, for each container.

**Delivered Amount**— Return the containers to the constant-temperature bath, continuing to deliver 5 second actuations to waste, until each container is exhausted. [note—Ensure that sufficient time is allowed between each actuation to avoid significant canister cooling.] Calculate the total weight loss from each container. This is the Delivered Amount.

##### Pressure Test

Perform this test only on topical aerosols fitted with continuous valves.

Select not fewer than four aerosol containers, remove the caps and covers, and immerse in a constant-temperature bath until the internal pressure is constant at a temperature of  $25^{\circ}$ . Remove the containers from the bath, shake, and remove the actuator and water, if any, from the valve stem. Place each container in an upright position, and determine the pressure in each container by placing a calibrated pressure gauge on the valve stem, holding firmly, and actuating the valve so that it is fully open. The gauge is of a calibration approximating the expected pressure and is fitted with an adapter appropriate for the particular valve stem dimensions. Read the pressure directly from the gauge.

##### Minimum Fill

Topical aerosols meet the requirements for aerosols under [Minimum Fill \(755\)](#).

##### Leakage Test

Perform this test only on topical aerosols fitted with continuous valves.

Select 12 aerosol containers, and record the date and time to the nearest half hour. Weigh each container to the nearest mg, and record the weight, in mg, of each as W1. Allow the containers to stand in an upright position at a temperature of  $25.0 \pm 2.0^{\circ}$  for not less than 3 days, and again weigh each container, recording the weight, in mg, of each as W2, and recording the date and time to the nearest half hour. Determine the time, T, in hours, during which the containers were under test. Calculate the leakage rate, in mg per year, of each container taken by the formula:

$$(365)(24)(T)(W1 - W2)$$

Where plastic-coated glass aerosol containers are tested, dry the containers in a desiccator for 12 to 18 hours, and allow them to stand in a constant-humidity environment for 24 hours prior to determining the initial weight as indicated above. Conduct the test under the same constant-humidity conditions. Empty the contents of each container tested by employing any safe technique (e.g., chill to reduce the internal pressure, remove the valve, and pour). Remove any residual contents by rinsing with suitable solvents, then rinse with a few portions of methanol. Retain as a unit the container, the valve, and all associated parts, and heat them at  $100^{\circ}$  for 5 minutes. Cool, weigh, record the weight as W3, and determine the net fill weight (W1 - W3) for each container tested. [note—If the average net fill weight has been determined previously, that value may be used in place of the value (W1 - W3) above.] The requirements are met if the average leakage rate per year for the 12 containers is not more than 3.5% of the net fill weight, and none of the containers leaks more than 5.0% of the net fill weight per year. If 1 container leaks more than 5.0% per year, and if none of the containers leaks more than 7.0% per year, determine the leakage rate of an additional 24 containers as directed herein. Not more than 2 of the 36 containers leak more than 5.0% of the net fill weight per year, and none of the 36 containers leaks more than 7.0% of the net fill weight per year. Where the net fill weight is less than 15 g and the label bears an expiration date, the requirements are met if the average leakage rate of the 12 containers is not more than 525 mg per year and none of the containers leaks more than 750 mg per year. If 1 container leaks more than 750 mg per year, but not more than 1.1 g per year, determine the leakage rate of an additional 24 containers as directed herein. Not more than 2 of the 36 containers leak more than 750 mg per year, and none of the 36 containers leaks more than 1.1 g per year. This test is in addition to the customary in-line leak testing of each container.

##### Number of Discharges per Container

Perform this test only on topical aerosols fitted with dose-metering valves, at the same time as, and on the same containers used for, the test for Delivered-Dose Uniformity. Determine

the number of discharges or deliveries by counting the number of priming discharges plus those used in determining the spray contents, and continue to fire until the label claim number of discharges. The requirements are met if all the containers or inhalers tested contain not less than the number of discharges stated on the label.

#### Delivered-Dose Uniformity

The test for Delivered-Dose Uniformity is required for topical aerosols fitted with dose-metering valves. For collection of the minimum dose, proceed as directed in the test for Delivered-Dose Uniformity under Metered-Dose Inhalers and Dry Powder Inhalers, as described below, except to modify the dose sampling apparatus so that it is capable of quantitatively capturing the delivered dose from the preparation being tested. Unless otherwise stated in the individual monograph, apply the acceptance criteria for Metered-Dose Inhalers and Dry Powder Inhalers as described below.

#### NASAL SPRAYS

The following test is applicable to nasal sprays, formulated as aqueous suspensions or solutions of drug, presented in multi-dose containers and fitted with dose-metering valves. In all cases, and for all tests, prepare and test the nasal spray as directed on the label and the instructions for use.

#### Delivered-Dose Uniformity

Unless otherwise directed in the individual monograph, the drug content of the minimum delivered doses (minimum number of sprays per nostril as described on the label, or instructions for use) collected at the beginning of unit life (after priming as described on the label, or instructions for use) and at the label claim number of metered sprays, from each of 10 separate containers, must meet the following acceptance criteria: not more than 2 of the 20 doses are outside the range of 80% to 120% of label claim, and none are outside the range of 75% to 125% of label claim, while the mean for each of the beginning and end doses falls within the range of 85% to 115% of label claim. If 3–6 doses of the 20 doses collected are outside of 80% to 120% of the label claim, but none are outside of 75% to 125% of label claim, and the means for each of the beginning and end doses fall within 85% to 115% of label claim, select 20 additional containers for second-tier testing. For second-tier testing, the requirements are met if not more than 6 of the 60 doses collected are outside the range of 80% to 120% of label claim, none are outside the range of 75% to 125% of label claim, and the means for each of the beginning and end doses fall within the range of 85% to 115% of label claim.

#### sampling for delivered-dose uniformity of metered-dose nasal sprays

**General Sampling Procedure**— To ensure reproducible in-vitro dose collection, it is recommended that a mechanical means of actuating the pump assembly be employed to deliver doses for collection. The mechanical actuation procedure should have adequate controls for the critical mechanical actuation parameters (e.g., actuation force, actuation speed, stroke length, rest periods, etc.). The test must be performed on units that have been primed according to the patient-use instructions. The test unit should be actuated in a vertical or near vertical, valve-up, position. The two doses collected at the beginning and end of the container life should be the dose immediately following priming and the dose corresponding to the last label claim number of doses from the container.

For suspension products, the delivered dose should be delivered into a suitable container (e.g., scintillation vial) in which quantitative transfer from the container under test can be accomplished. A validated analytical method is employed to determine the amount of drug in each delivered dose, and data are reported as a percent of label claim. For solution products, the delivered dose can be determined gravimetrically from the weight of the delivered dose, and the concentration and density of the fill solution of the product under test.

#### METERED-DOSE INHALERS AND DRY POWDER INHALERS

The following tests are applicable to metered-dose inhalers that are formulated as suspensions or solutions of active drug in propellants and dry powder inhalers presented as single or multidose units. The following test methods are specific to the aforementioned inhalers and may require modification when testing alternative inhalation technologies (for example, breath-actuated metered-dose inhalers, or dose-metering nebulizers). However, Pharmacopeial requirements for all dose-metering inhalation dosage forms require determination of the delivered dose and Aerodynamic Size Distribution. In all cases, and for all tests, prepare and test the inhaler as directed on the label and the instructions for use. When these directions are not provided by the product manufacturer, follow the precise dose discharge directions included in the tests below.

#### Delivered-Dose Uniformity

The test for Delivered-Dose Uniformity is required for inhalers (e.g., metered-dose inhalers or dry powder inhalers) containing drug formulation (e.g., solution, suspension, or powder) either in reservoirs or in premetered dosage units, and for drug formulations packaged in reservoirs or in premetered dosage units where these containers are labeled for use with a named inhalation device. (For inhalations packaged in premetered dosage units, see also [Uniformity of Dosage Units \(905\)](#).) Note that the target-delivered dose is the expected mean drug content for a large number of delivered doses collected from many inhalers of the chosen product. In many cases, its value may depend upon the manner in which the test for delivered dose is performed. For metered-dose inhalers, the target-delivered dose is specified by the label claim, unless otherwise specified in the individual monograph. For dry powder inhalers, where the label claim is usually the packaged or metered-dose of drug, the target-delivered dose is specified in the individual monograph and is usually less than the label claim. Its value reflects the expected mean drug content for a large number of delivered doses collected from the product, using the method specified in the monograph.

Unless otherwise directed in the individual monograph, the drug content of the minimum delivered dose from each of 10 separate containers is determined in accordance with the procedure described below.

Unless otherwise specified in the individual monograph, the requirements for dosage uniformity are met if not less than 9 of the 10 doses are between 75% and 125% of the specified target-delivered dose and none is outside the range of 65% to 135% of the specified target-delivered dose. If the contents of not more than 3 doses are outside the range of 75% to 125% of the specified target-delivered dose, but within the range of 65% to 135% of the specified target-delivered dose, select 20 additional containers, and follow the prescribed procedure for analyzing 1 minimum dose from each. The requirements are met if not more than 3 results, out of the 30 values, lie outside the range of 75% to 125% of the specified target-delivered dose, and none is outside the range of 65% to 135% of the specified target-delivered dose.

#### sampling the delivered dose from metered-dose inhalers

To determine the content of active ingredient in the discharged spray from a metered-dose inhaler, use the sampling apparatus described below, using a flow rate of 28.3 L of air per minute ( $\pm 5\%$ ), unless otherwise stated in the individual monograph.

**Apparatus A— The apparatus (see [Figure 1](#))**

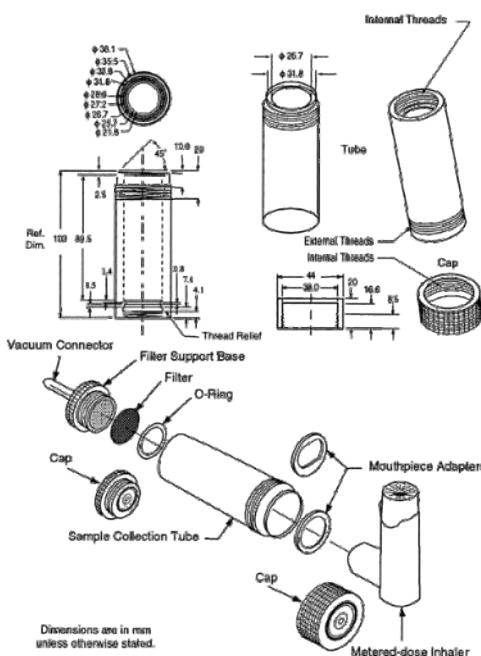

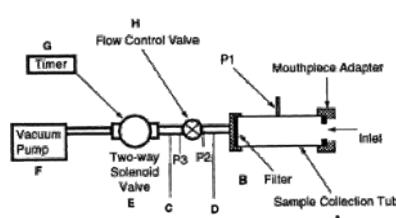

Fig. 1. Sampling apparatus for pressurized metered-dose inhalers.

consists of a filter support base with an open-mesh filter support, such as a stainless steel screen, a collection tube that is clamped or screwed to the filter support base, and a mouthpiece adapter to ensure an airtight seal between the collection tube and the mouthpiece. Use a mouthpiece adapter that ensures that the opening of the inhaler mouthpiece is flush with the front face or 2.5-mm indented shoulder in the sample collection tube, as appropriate. The vacuum connector is connected to a system comprising a vacuum source, flow regulator, and flowmeter. The source should be capable of pulling air through the complete assembly, including the filter and the inhaler to be tested, at the desired flow rate. When testing metered-dose inhalers, air should be drawn continuously through the system to avoid loss of drug into the atmosphere. The filter support base is designed to accommodate 25-mm diameter filter disks. At the airflow being used, the sample collection tube and the filter disk must be capable of quantitatively collecting the Delivered Dose. The filter disk and other materials used in the construction of the apparatus must be compatible with the drug and the solvents that are used to extract the drug from the filter. One end of the collection tube is designed to hold the filter disk tightly against the filter support base. When assembled, the joints between the components of the apparatus are airtight so that when a vacuum is applied to the base of the filter, all of the air drawn through the collection device passes through the inhaler.

**Procedure**— Prepare the inhaler for use according to the label instructions. Unless otherwise specified in the individual monograph, with the vacuum pump running, ensuring an airflow rate through the inhaler of 28.3 L of air per minute ( $\pm 5\%$ ), discharge the minimum recommended dose into the apparatus through the mouthpiece adapter by depressing the valve for a duration sufficient to ensure that the dose has been completely discharged. Detach the inhaler from Apparatus A, and disconnect the vacuum. Assay the contents of the apparatus for drug after rinsing the filter and the interior of the apparatus with a suitable solvent.

sampling the delivered dose from dry powder inhalers

To determine the content of active ingredient emitted from the mouthpiece of a dry powder inhaler, use Apparatus B (see [Figure 2](#)).

Fig. 2. Apparatus B: Sampling apparatus for dry powder inhalers. (See [Table 1](#) for component specifications.)Table 1. Component Specifications for Apparatus B (see [Fig. 2](#))

Code	Item	Description	Dimensions
A	Sample collection tube <sup>a</sup>	See <a href="#">Fig. 2</a>	34.85-mm ID $\times$ 12-cm length
B	Filter <sup>b</sup>	See <a href="#">Fig. 2</a>	47-mm glass fiber filter
C	Connector	(e.g., short metal coupling with low diameter branch to P3)	$\geq 8$ -mm ID
D	Vacuum tubing	(e.g., silicon tubing with an outside diameter of 14 mm and an internal diameter of 8 mm)	a length of suitable tubing $\geq 8$ mm ID with an internal volume of 25 $\pm 5$ mL
E	Two-way solenoid valve <sup>c</sup>	See <a href="#">Fig. 2</a>	2-way, 2-port solenoid valve having an ID $\geq 8$ mm and an opening response time of $\leq 100$ milliseconds.
F	Vacuum pump <sup>d</sup>	See <a href="#">Fig. 2</a>	Pump must be capable of drawing the required flow rate through the assembled apparatus with the dry powder inhaler in the mouthpiece adapter. Connect the pump to the solenoid valve using short and wide ( $\geq 10$ -mm ID) vacuum tubing and connectors to minimize pump capacity requirements.

G	Timer <sup>a</sup>	See <a href="#">Fig. 2</a>	The timer switches current directly to the solenoid valve for the required duration.
P1	pressure tap	See <a href="#">Fig. 2</a>	2.2-mm ID, 3.1-mm OD flush with the internal surface of the sample collection tube, centered and burr free, 59 mm from its inlet. The pressure taps P1, P2, and P3 must not be open to the atmosphere during dose collection.
P1, P2, P3	pressure measurements <sup>f</sup>		
H	Flow-control valve <sup>g</sup>	See <a href="#">Fig. 2</a>	Adjustable regulating valve with maximum Cv $\geq 1^h$ .

h Flow Coefficient, as defined by ISA S75.02 "Control valve capacity test procedure" in Standards and Recommended Practices for Instrumentation and Control, 10th ed., Vol. 2, 1989. Published by Instrument Society of America, 67 Alexander Drive, P.O. Box 1227, Research Triangle Park, NC 27709, U.S.A.

This apparatus is capable of sampling the emitted doses at a variety of airflow rates.

Apparatus B—The apparatus is similar to that described in [Figure 1](#) for testing metered-dose inhalers. In this case, however, the filter and collection tube have a larger internal diameter to accommodate 47-mm diameter filter disks. This feature enables dosage collection at higher airflow rates—up to 100 L of air per minute—when necessary. A mouthpiece adapter ensures an airtight seal between the collection tube and the mouthpiece of the dry powder inhaler being tested. The mouthpiece adapter must ensure that the tip of the inhaler mouthpiece is flush with the open end of the sample collection tube. Tubing connectors, if they are used, should have an internal diameter greater than or equal to 8 mm to preclude their own internal diameters from creating significant airflow resistance. A vacuum pump with excess capacity must be selected in order to draw air, at the designated volumetric flow rate, through both the sampling apparatus and the inhaler simultaneously. A timer-controlled, low resistance, solenoid-operated, two-way valve is interposed between the vacuum pump and the flow-control valve to control the duration of flow. This type of valve enables 4.0 L of air ( $\pm 5\%$ ) to be withdrawn from the mouthpiece of the inhaler at the designated flow rate. Flow control is achieved by ensuring that critical (sonic) flow occurs in the flow-control valve (absolute pressure ratio P3/P2  $\leq 0.5$  under conditions of steady-state flow).

Procedure—Operate the apparatus at an airflow rate that produces a pressure drop of 4 kPa (40.8 cm H<sub>2</sub>O) over the inhaler to be tested and at a duration consistent with the withdrawal of 4 L of air from the mouthpiece of the inhaler. [note—If the flow rate and duration are defined otherwise in the monograph, adjust the system to within 5% of those values.]

Determine the test flow rate using Apparatus B as follows. Insert an inhaler into the mouthpiece adapter to ensure an airtight seal. In cases where the drug packaging modifies the inhaler's resistance to airflow, use a loaded, drug-free inhaler (with previously emptied packaging). In other cases, use an unloaded (drug free) inhaler. Connect one port of a differential pressure transducer to the pressure tap, P1, and leave the other open to the atmosphere. Switch on the pump, and open the two-way solenoid valve. Adjust the flow-control valve until the pressure drop across the inhaler is 4.0 kPa (40.8 cm H<sub>2</sub>O). Ensure that critical (sonic) flow occurs in the flow-control valve by determining the individual values for absolute pressure, P2 and P3, so that their ratio P3/P2 is less than or equal to 0.5. If this criterion cannot be achieved, it is likely that the vacuum pump is worn or of insufficient capacity. Critical (sonic) flow conditions in the flow-control valve are required in order to ensure that the volumetric airflow drawn from the mouthpiece is unaffected by pump fluctuations and changes in airflow resistance of the inhaler. Remove the inhaler from the mouthpiece adapter and without disturbing the flow-control valve, measure the airflow rate drawn from the mouthpiece, Qout, by connecting a flowmeter to the mouthpiece adaptor in an airtight fashion. Use a flowmeter calibrated for the volumetric flow leaving the meter in an airtight fashion to directly determine Qout or, if such a meter is unobtainable, calculate the volumetric flow leaving the meter (Qout) using the ideal gas law. For example, for a meter calibrated for the entering volumetric flow (Qin), use the formula:

$$Qout = QinP0 / (P0 - \Delta P)$$

where P0 is the atmospheric pressure and  $\Delta P$  is the pressure drop over the meter. If the flow rate is greater than 100 L of air per minute, adjust the flow-control valve until Qout equals 100 L per minute; otherwise, record the value of Qout, and leave the flow-control valve undisturbed. Define the test flow duration, T = 240/Qout, in seconds, so that a volume of 4.0 L of air ( $\pm 5\%$ ) is withdrawn from the inhaler at the test flow rate Qout, and adjust the timer controlling the operation of the two-way solenoid valve accordingly. Prime or load the inhaler with powder for inhalation according to the labeled instructions. With the vacuum pump running and the solenoid valve closed, insert the inhaler mouthpiece horizontally into the mouthpiece adapter. Discharge the powder into the sampling apparatus by activating the timer controlling the solenoid valve and withdrawing 4.0 L of air from the inhaler at the previously defined airflow rate. If the labeled instructions so direct, repeat the operation so as to simulate the use of the inhaler by the patient (e.g., inhale two or three times, if necessary, to empty the capsule). Repeat the whole operation  $n - 1$  times beginning with the text, "Prime or load the inhaler with powder," where n is the number of times defined in the labeling as the minimum recommended dose. Detach the dry powder inhaler from the sampling apparatus, and disconnect the vacuum tubing, D. Assay the contents of the apparatus for drug after rinsing the filter and the interior of the apparatus with a suitable solvent. Where specified in individual monographs, perform this test under conditions of controlled temperature and humidity.

#### Delivered-Dose Uniformity over the Entire Contents

The test for Delivered-Dose Uniformity over the Entire Contents is required for inhalers (e.g., metered-dose inhalers or dry powder inhalers) containing multiple doses of drug formulation (e.g., solution, suspension, or dry powder) either in reservoirs or in premetered dosage units (e.g., blisters), and for drug formulations packaged in reservoirs or in multiple-dose assemblies of premetered dosage units that have a predetermined dose sequence, where these multiple-dose assemblies are labeled for use with a named inhalation device.

The test for Delivered-Dose Uniformity over the Entire Contents also ensures that multidose products supply the total number of discharges stated on the label. Unless otherwise directed in the individual monograph, the drug content of at least 9 of the 10 doses collected from one inhaler, in accordance with the procedure below, are between 75% and 125% of the target-delivered dose, and none is outside the range of 65% to 135% of the target-delivered dose. If the contents of not more than 3 doses are outside the range of 75% to 125%, but within the range of 65% to 135% of the target-delivered dose, select 2 additional inhalers, and follow the prescribed procedure for analyzing 10 doses from each. The requirements are met if not more than 3 results, out of the 30 values, lie outside the range of 75% to 125% of the target-delivered dose, and none is outside the range of 65% to 135% of the target-

delivered dose.

#### metered-dose inhalers

Apparatus— Use Apparatus A as directed in Sampling the Delivered-Dose from Metered-Dose Inhalers under Delivered-Dose Uniformity at a flow rate of 28.3 L of air per minute ( $\pm 5\%$ ).

Procedure— A single dose is defined as the number of sprays specified in the product labeling as the minimum recommended dose. Select a single metered-dose inhaler, and follow the labeled instructions for priming, shaking, cleaning, and firing the inhaler throughout. Unless otherwise prescribed in the patient instructions, shake the inhaler for 5 seconds, and fire one minimum recommended dose to waste. Wait for 5 seconds, and collect the next dose. Detach the inhaler from Apparatus A, and disconnect the vacuum. Assay the contents of the apparatus for drug after rinsing the filter and the interior of the apparatus with a suitable solvent. Collect two more doses, allowing at least 5 seconds between doses. Discharge the device to waste, waiting for not less than 5 seconds between actuations (unless otherwise specified in the individual monograph), until  $(n/2) + 1$  minimum recommended doses remain, in which  $n$  is the number of minimum recommended doses on the label. Collect four more doses, allowing at least 5 seconds between doses, unless otherwise specified in the individual monograph. Discharge the device to waste, as before, until three doses remain. Collect the final three doses, allowing at least 5 seconds between doses. Note that the rate of discharges to waste should not be such as to cause excessive canister cooling.

#### dry powder inhalers

Apparatus— Use Apparatus B as directed in Sampling the Delivered Dose from Dry Powder Inhalers under Delivered-Dose Uniformity at the appropriate airflow rate for testing.

Procedure— Proceed as directed for Procedure in Sampling the Delivered Dose from Dry Powder Inhalers under Delivered-Dose Uniformity. A single dose is defined as the number of actuations stated in the product labeling as the minimum recommended dose. Select a single inhaler and follow the labeled instructions for loading with powder, discharging and cleaning throughout. Collect a total of 10 doses—three doses at the beginning, four in the middle [ $(n/2) - 1$  to  $(n/2) + 2$ , where  $n$  is the number of minimum recommended doses on the label], and three at the end—of the labeled contents following the labeled instructions. Prior to collecting each of the doses to be analyzed, clean the inhaler as directed in the labeling.

#### Particle Size

The particle or droplet size distribution in the spray discharged from metered-dose inhalers, and the particle size distribution in the cloud discharged from dry powder inhalers, are important characteristics used in judging inhaler performance. While particle size measurement by microscopy can be used to evaluate the number of large particles, agglomerates, and foreign particulates in the emissions of metered-dose inhalers (e.g., Epinephrine Bitartrate Inhalation Aerosol), whenever possible this test should be replaced with a method to determine the aerodynamic size distribution of the drug aerosol leaving the inhaler. The aerodynamic size distribution defines the manner in which an aerosol deposits during inhalation. When there is a log-normal distribution, the aerodynamic size distribution may be characterized by the mass median aerodynamic diameter (MMAD) and geometric standard deviation (GSD). The aerodynamic size distribution of the drug leaving metered-dose and dry powder inhalers is determined using Apparatus 1, 2, 3, 4, 5, or 6 as specified in this chapter. A fine particle dose or fine particle fraction can also be determined as that portion of the inhaler output having an aerodynamic diameter less than the size defined in the individual monograph. This may be expected to correlate with the drug dose or that fraction of the drug dose that penetrates the lung during inhalation. Individual monographs may also define the emitted fractions of the delivered dose in more than one aerodynamic size range.

#### aerodynamic size distribution

Cascade impaction devices classify aerosol particles and droplets on the basis of those particles' aerodynamic diameters. The principle of their operation, whereby they separate aerosol particles and droplets from a moving airstream on the basis of particle or droplet inertia, is shown in [Figure 3](#).

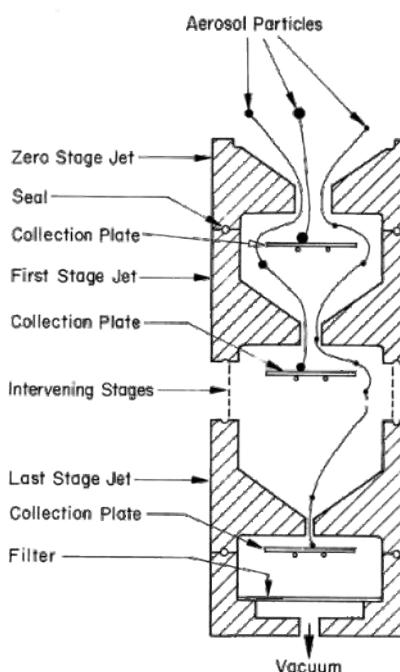

Fig. 3. Schematic representation of the principle of operation of cascade impactors. (A single jet per impactor stage is shown. Impactors with multiple jets in each stage function in the same manner.)

Because the dimensions of the induction port used to connect inhalers to the cascade impactors and impingers (shown in Apparatus 1, 2, 3, 4, 5, and 6) also define the mass of drug that enters the aerodynamic sizing device, these are carefully defined and, where possible, are held constant between each apparatus (see [Figures 4, 6, 7, 8, and 9](#)).

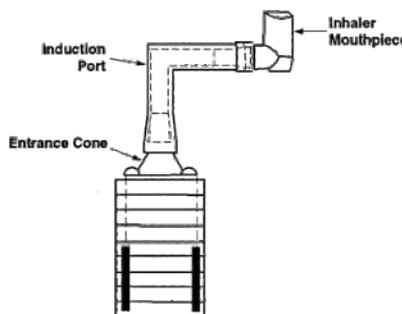

Fig. 4. Apparatus 1: Assembly of induction port and entrance cone mounted on cascade impactor.

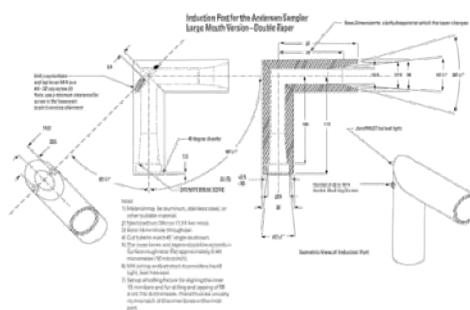

Fig. 4a. Apparatus 1: Expanded view of induction port for use with metered-dose and dry powder inhalers.

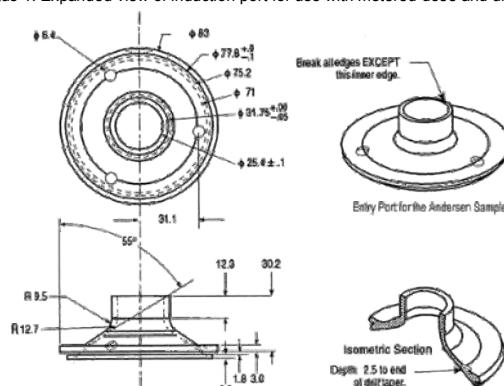

Fig. 4b. Apparatus 1: Expanded view of the entrance cone for mounting induction port on the Andersen cascade impactor without preseparators. Material may be aluminum, stainless steel, or other suitable material. Surface roughness (Ra) should be approximately 0.4  $\mu\text{m}$ .

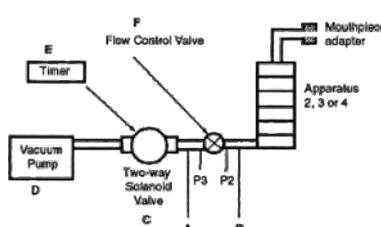

Fig. 5. Apparatus 2, 3, 4, or 5: General control equipment. (See [Table 3](#) for component specifications.)

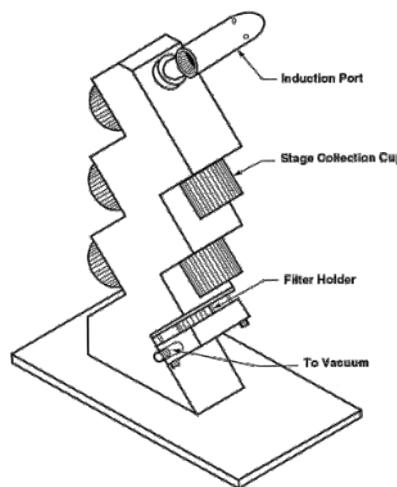

Fig. 6. Apparatus 2: Assembly of induction port, stage collector, and filter holder. (Marple-Miller impactor, Model 160 with USP induction port.)

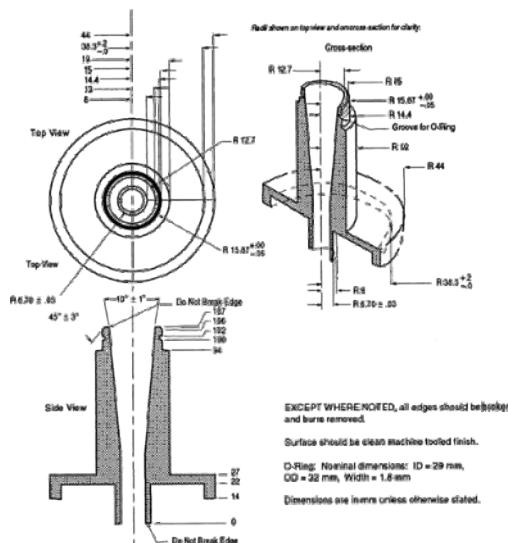

Fig. 7. Apparatus 3: Expanded views of top for the Andersen preseparator adapted to the USP induction port. Material may be aluminum, stainless steel, or other suitable material; interior bore should be polished to surface roughness ( $R_a$ ) approximately 0.4  $\mu\text{m}$ .

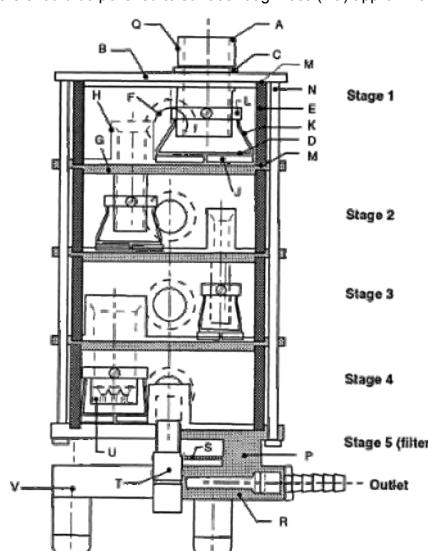

Fig. 8. Apparatus 4: Schematic of multistage liquid impinger. (See Table 4 for component specifications.)

Because the size distributions produced by different impactors are often a function of impactor design and the airflow rate through them, there is a need to standardize the instruments that are used to test inhalers (i.e., Apparatus 1 or 6 for metered-dose inhalers) or to provide guidelines on system suitability where different apparatuses may be used (i.e., Apparatus 2, 3, 4, or 5 for dry powder inhalers).

Because of the varied nature of the formulations and devices being tested, the cascade impaction system and technique selected for testing an inhaler should fulfill a number of criteria.

**Stage Mensuration**— Manufacturers of cascade impaction devices provide a definitive calibration for the separation characteristics of each impaction stage in terms of the relationship between the stage collection efficiency and the aerodynamic diameter of particles and droplets passing through it as an aerosol. Calibration is a property of the jet dimensions, the spatial arrangement of the jet and its collection surface, and the airflow rate passing through it. Because jets can corrode and wear over time, the critical dimensions of each stage,

...which define that impaction stage's calibration, must be measured on a regular basis. This process, known as stage mensuration, replaces the need for repetitive calibration (using standard aerosols) and ensures that only devices that conform to specifications are used for testing inhaler output. The process involves the measurement and adjustment of the critical dimensions of the instrument.

**Interstage Drug Loss (wall losses)—** Where method variations are possible and there is no apparatus specified in the monograph, the selected technique should ensure that not more than 5% of the inhaler's total delivered drug mass (into the impactor) is subject to loss between the impaction device's sample collection surfaces. In the event that interstage drug losses are known to be greater than 5%, either the procedure should be performed in such a way that wall losses are included along with the associated collection plate, or an alternative apparatus should be used. As an example, the following procedures described for Apparatus 1 and 3 have been written to include wall losses along with the associated collection plate. Provided, however, that such losses are known to be less than or equal to 5% of the total delivered drug mass into the impactor and that there are no instructions to the contrary in an individual monograph, the technique may be simplified by only assaying drug on the collection plates.

**Re-Entrainment—** Where method variations are possible, the selected technique should seek to minimize particle re-entrainment (from an upper to a lower impaction stage) on stages that contribute to size fractions defined in the individual monograph, especially where this may affect the amounts of drug collected. Minimizing the number of sampled doses, the use of coated particle collection surfaces, and proving that multiple-dose techniques produce statistically similar results to those from smaller numbers of doses, are all methods that can be used for this purpose. In the event that re-entrainment cannot be avoided, the number of doses collected, the time interval between doses, and the total duration of airflow through the cascade impaction device should be standardized. Under these circumstances, the presentation of impaction data should not presume the validity of the impactor's calibration (i.e., aerodynamic diameter ranges should not be assigned to drug masses collected on specific stages).

By using appropriate assay methods and a suitable mensurated impaction device, aerodynamic particle size distributions can be determined for drugs leaving the mouthpieces of metered-dose or dry powder inhalers. If temperature or humidity limits for use of the inhaler are stated on the label, it may be necessary to control the temperature and humidity of the air surrounding and passing through the device to conform to those limits. Ambient conditions are presumed, unless otherwise specified in individual monographs.

**Mass Balance—** In addition to the size distribution, good analytical practice dictates that a mass-balance be performed in order to confirm that the amount of the drug discharged from the inhaler, which is captured and measured in the induction port-cascade impactor apparatus, is within an acceptable range around the expected value. The total mass of drug collected in all of the components (material balance) divided by the total number of minimum recommended doses discharged is not less than 75% and not more than 125% of the average minimum recommended dose determined during testing for Delivered-Dose Uniformity. This is not a test of the inhaler but serves to ensure that the test results are valid.

Use one of the multistage impaction devices shown below, or an equivalent, to determine aerodynamic particle size distributions of drugs leaving the mouthpieces of metered-dose or dry powder inhalers. Apparatus 1 and 6 (Figures 4 and 9 (without preseparator), respectively) are intended for use with metered-dose inhalers at a single airflow rate. Apparatus 2, 3, 4, and 5 (Figures 6, 7, 8, and 9, respectively) are intended for use with dry powder inhalers at the appropriate airflow rate,  $Q_{out}$ , determined earlier, provided that the value of  $Q_{out}$  falls in the range 30–100 L per minute.

**note—**If  $Q_{out}$  is greater than 100 L per minute, testing should be performed with  $Q_{out}$  set at 100 L per minute; if  $Q_{out}$  is less than 30 L per minute, testing is performed with  $Q_{out}$  at 30 L per minute.

**Apparatus 1 for Metered-Dose Inhalers—** Use this apparatus, or an equivalent, at a flow rate of 28.3 L per minute ( $\pm 5\%$ ), as specified by the manufacturer of the cascade impactor.

**Design—** The design and assembly of this apparatus and the induction port to connect the device to an inhaler are shown in Figures 4, 4a, and 4b<sup>4</sup>.

Critical engineering dimensions applied by manufacturers to the stages of Apparatus 1 are provided in Table 2. During use, some occlusion and blockage of jet nozzles may occur and therefore, "in use" mensuration tolerances need to be justified.

Table 2. Critical Dimensions for the Jet Nozzles of Apparatus 1

Stage #	Number of Jets	Nozzle Diameter (mm)
0	96	$2.55 \pm 0.025$
1	96	$1.89 \pm 0.025$
2	400	$0.914 \pm 0.0127$
3	400	$0.711 \pm 0.0127$
4	400	$0.533 \pm 0.0127$
5	400	$0.343 \pm 0.0127$
6	400	$0.254 \pm 0.0127$
7	201	$0.254 \pm 0.0127$

**Procedure—** Set up the multistage cascade impactor as described in the manufacturer's literature with an after filter below the final stage to capture any fine particles that otherwise would escape from the device. To ensure efficient particle capture, coat the particle collection surface of each stage with glycerol, silicone oil, or other suitable liquid typically deposited from a volatile solvent, unless it has been demonstrated to be unnecessary. Attach the induction port and mouthpiece adapter to produce an airtight seal between the inhaler mouthpiece and the induction port as shown in Figure 4. Use a mouthpiece adapter that ensures that the tip of the inhaler mouthpiece is flush with the open end of the induction port. Ensure that the various stages of the cascade impactor are connected with airtight seals to prevent leaks. Turn on the vacuum pump to draw air through the cascade impactor, and calibrate the airflow through the system with an appropriate flowmeter attached to the open end of the induction port. Adjust the flow-control valve on the vacuum pump to achieve steady flow through the system at the required rate, and ensure that the airflow through the system is within  $\pm 5\%$  of the flow rate specified by the manufacturer. Unless otherwise prescribed in the patient instructions, shake the inhaler for 5 seconds and discharge one delivery to waste. With the vacuum pump running, insert the mouthpiece into the mouthpiece adapter and immediately fire the minimum recommended dose into the cascade impactor. Keep the valve depressed for a duration sufficient to ensure that the dose has been completely discharged. If additional sprays are required for the sample, wait for 5 seconds before removing the inhaler from the mouthpiece adapter, shake the inhaler, reinsert it into the mouthpiece adapter, and immediately fire the next minimum recommended dose. Repeat until the required number of doses have been discharged. The number of minimum recommended doses discharged must be sufficient to ensure an accurate and precise determination of Aerodynamic Size Distribution. [note—The number of minimum recommended doses is typically not greater than 10.] After the last dose has been discharged, remove the inhaler from the mouthpiece adapter. Rinse the mouthpiece adapter and induction port with a suitable solvent, and dilute quantitatively to an appropriate volume. Disassemble the cascade impactor, place each stage and its associated collection plate or filter in a separate container, and rinse the drug from each of them. [note—If it has been determined that wall losses in the impactor are less than or equal to 5%, then the collection plates only may be used.]

Dilute each quantitatively to an appropriate volume. Using the method of analysis specified in the individual monograph, determine the mass of drug collected in each of the components. To analyze the data, proceed as directed under Data Analysis.

#### Apparatus 2 for Dry Powder Inhalers—

**Design—** The design and assembly of Apparatus 2, and the induction port to connect the device to an inhaler, are shown in Figure 6.<sup>2</sup> [note—The induction port is shown in detail in Figure 4a.] The impactor has five impaction stages and an after filter. At a volumetric airflow rate of 60 L per minute (the nominal flow rate,  $Q_n$ ), the cutoff aerodynamic diameters  $D_{50,Qn}$  of Stages 1 to 5 are 10, 5, 2.5, 1.25, and 0.625  $\mu\text{m}$ , respectively. The after filter effectively retains aerosolized drug in the particle size range up to 0.625  $\mu\text{m}$ . Set up the multistage cascade impactor with the control system as specified in Figure 5. To ensure efficient particle capture, coat the particle collection surface of each stage with glycerol, silicone oil, or other suitable liquid typically deposited from a volatile solvent, unless it has been demonstrated to be unnecessary. Assemble the impactor as described in the manufacturer's literature with an after filter below the final stage to capture any fine particles that otherwise would escape from the device. Attach the induction port and mouthpiece adapter to produce an airtight seal between the inhaler mouthpiece and the induction port. Use a mouthpiece adapter that ensures that the tip of the inhaler mouthpiece is flush with the open end of the induction port. Ensure that the various stages of the cascade impactor are connected with airtight seals to prevent leaks.

Turn on the vacuum pump, open the solenoid valve, and calibrate the airflow through the system as follows. Connect a flowmeter to the induction port. Use a flowmeter calibrated for the volumetric flow leaving the meter to directly determine  $Q_{out}$ , or, if such a meter is unobtainable, calculate the volumetric flow leaving the meter ( $Q_{out}$ ) using the ideal gas law. For

example, for a meter calibrated for the entering volumetric flow ( $Q_{in}$ ), use the formula:

$$Q_{out} = Q_{in}P_0 / (P_0 - \Delta P)$$

where  $P_0$  is the atmospheric pressure and  $\Delta P$  is the pressure drop over the meter. Adjust the flow-control valve to achieve a steady flow through the system at the required rate,  $Q_{out}$ , so that  $Q_{out}$  is within  $\pm 5\%$  of the value determined during testing for Delivered-Dose Uniformity. Ensure that critical flow occurs in the flow-control valve, at the airflow rate to be used during testing, by using the following procedure. With the inhaler in place, and the intended flow running, measure the absolute pressure on both sides of the flow-control valve ( $P_2$  and  $P_3$  in [Figure 5](#)). A ratio of  $P_3/P_2 \leq 0.5$  indicates critical flow. Switch to a more powerful pump, and remeasure the test flow rate if  $P_3/P_2 > 0.5$ . Adjust the timer controlling the operation of the two-way solenoid valve so that it opens this valve for a duration of  $T$  seconds as determined during testing for Delivered-Dose Uniformity. Prime or load the dry powder inhaler with powder for inhalation according to the labeled instructions. With the vacuum pump running and the two-way solenoid valve closed, insert the inhaler mouthpiece, held horizontally, into the induction port mouthpiece adapter. Discharge the powder into the apparatus by opening the two-way solenoid valve for a duration of  $T$  seconds. After the two-way solenoid valve has closed, remove the inhaler from the mouthpiece adapter. If additional doses are required for the sample, reload the inhaler according to the labeled instructions, reinsert the mouthpiece into the mouthpiece adapter, and repeat the operation until the required number of doses have been discharged. After discharge of the last dose, switch off the vacuum pump.

Rinse the mouthpiece adapter and induction port with a suitable solvent, and quantitatively dilute to an appropriate volume. Disassemble the cascade impactor, and place the after filter in a separate container. Rinse the drug from each of the stages and the filter, and quantitatively dilute each to an appropriate volume. Using the method of analysis specified in the individual monograph, determine the mass of drug collected in each of the components. Determine the cutoff diameters of each of the individual stages of the impactor, at the value of

$$Q = Q_{out} \text{ employed in the test by the formula:}$$

$$D_{50,Q} = D_{50,Qn}(Q_n / Q_1) / 2, \text{ (Eq. 1)}$$

where  $D_{50,Q}$  is the cutoff diameter at the flow rate,  $Q$ , employed in the test, and the subscript,  $n$ , refers to the nominal values determined when  $Q_n$  equals 60 L per minute. Thus, when  $Q$  equals 40 L per minute, the cutoff diameter of Stage 2 is given by the formula:

$$D_{50,40LPM} = 5 \mu\text{m} \times [60/40]1 / 2 = 6.1 \mu\text{m}.$$

**General Procedure**— Perform the test using Apparatus 2 at the airflow rate,  $Q_{out}$  determined earlier, during testing for Delivered-Dose Uniformity, provided  $Q_{out}$  is less than or equal to 100 L per minute. [note—If  $Q_{out}$  is greater than 100 L per minute, use an airflow rate of 100 L per minute.] Connect the apparatus to a flow control system that is based upon critical (sonic) flow as specified in [Figure 5](#) (see also [Table 3](#)).

Table 3. Component Specifications for [Figure 5](#)

Code	Item	Description	Dimensions
A	Connector	(e.g., short metal coupling with low diameter branch to $P_3$ )	$\geq 8\text{-mm ID}$
B	Vacuum tubing	(e.g., silicon tubing with an outside diameter of 14 mm and an internal diameter of 8 mm)	A length of suitable tubing $\geq 8$ mm ID with an internal volume of $25 \pm 5$ mL.
C	Two-way solenoid valve <sup>a</sup>	See Fig. 5	2-way, 2-port solenoid valve having an ID $\geq 8$ mm and an opening response time of $\leq 100$ milliseconds.
D	Vacuum pump <sup>b</sup>	See Fig. 5	Pump must be capable of drawing the required flow rate through the assembled apparatus with the dry powder inhaler in the mouthpiece adapter. Connect the pump to the solenoid valve using short and wide ( $\geq 10$ -mm ID) vacuum tubing and connectors to minimize pump capacity requirements.
E P2, P3	Timer <sup>c</sup> Pressure measurements	See Fig. 5	The timer switches current directly to the solenoid valve for the required duration. Determine under steady-state flow conditions with an absolute pressure transducer.
F	Flow control valve <sup>d</sup>	See Fig. 5	Adjustable regulating valve with maximum $C_v \geq 1$ .

<sup>a</sup> An example being ASCO product number 8030G13 (Automatic Switch Company, 60 Hanover Road, Florham Park, NJ 07932) or equivalent. See also Footnote h in [Table 1](#).

<sup>b</sup> Gast product type 1023, 1423, or 2565 (Gast Manufacturing Inc., PO Box 97, Benton Harbor, MI 49022) or equivalent.

<sup>c</sup> An example being Eaton Product number 45610-400 (Eaton Corporation, Automotive Products Division, 901 South 12th Street, Watertown, WI 53094) or equivalent.

<sup>d</sup> Parker Hannifin type 8FV12LNSS, or equivalent (Parker Hannifin plc, Riverside Road, Barnstable, Devon EX31 1NP, UK). See also Footnote h in [Table 1](#).

Table 4. Component Units of Multistage Liquid Impinger (see [Figure 8](#))

Code <sup>1</sup>	Item	Description	Dimensions <sup>2</sup>
A,H	Jet tube	Metal tube screwed onto partition wall sealed by gasket (C), polished inner surface	see <a href="#">Figure 8a</a>
B,G	Partition wall	Circular metal plate, diameter	120
		Thickness	see <a href="#">Figure 8a</a>
C	Gasket	e.g., PTFE	to fit jet tube
D	Impaction plate	Porosity O sintered-glass disk,	
		Diameter	see <a href="#">Figure 8a</a>
E	Glass cylinder	Plane polished cut glass tube	
		Height, including gaskets	46
		Outer diameter	100
		Wall thickness	3.5

	Sampling port (F) diameter	18
	Stopper in sampling port	ISO 24/25
J	Metal frame	I-profiled circular frame with slit
	Inner diameter	to fit impaction plate
	Height	4
	Thickness of horizontal section	0.5
	Thickness of vertical section	2
K	Wire	Steel wire interconnecting metal frame and sleeve (two for each frame)
	Diameter	1
L	Sleeve	Metal sleeve secured on jet tube by screw
	Inner diameter	to fit jet tube
	Height	6
	Thickness	5
M	Gasket	e.g., silicone
		to fit glass cylinder
N	Bolt	Metal bolt with nut (six pairs), length
	Diameter	4
P	O-ring	Rubber O-ring, diameter $\times$ thickness
Q	O-ring	Rubber O-ring, diameter $\times$ thickness
R	Filter holder	Metal housing with stand and outlet
S	Filter support	Perforated sheet metal, diameter
	Hole diameter	65
	Distance between holes (center-points)	3
T	Snap-locks	
U	Multi-jet tube	Jet tube (H) ending in multijet arrangement
V	Outlet	Outlet and nozzle for connection to vacuum
		Internal diameter $\geq 10$ (Figure 8b)

n.a.: not applicable.

Under steady flow conditions, at the appropriate volumetric airflow rate through the entire apparatus, ensure that critical (sonic) flow occurs in the flow control valve by determining the individual values for absolute pressure, P2 and P3, so that their ratio P3/P2 is less than or equal to 0.5. Coat the particle collection surface of each of the stages of the cascade impactor to ensure that particles that have impacted on a given stage are not re-entrained in the flowing airstream, unless this has been shown to be unnecessary. Analyze the data as directed under Data Analysis.

#### Apparatus 3 for Dry Powder Inhalers—

Design— Apparatus 3 is identical to [Apparatus 1 \(Figure 4\)](#), except that the manufacturer's preseparator is added atop Stage 0 to collect large masses of noninhalable powder prior to their entry into the impactor, and the outlet nipple, used to connect to vacuum tubing B ([Figure 5](#)), is replaced with one having an internal diameter  $\geq 8$  mm. To connect the preseparator of the impactor to the induction port ([Figure 4a](#)), a specially designed top for the preseparator must be used. This is shown in [Figure 7<sup>3</sup>](#). The impactor, therefore, has eight stages, a preseparator (to collect large particulates), and an after filter. At a volumetric airflow rate of 28.3 L per minute (the nominal flow rate, Qn), the cutoff aerodynamic diameters D50,Qn of Stages 0 to 7 are 9.0, 5.8, 4.7, 3.3, 2.1, 1.1, 0.7, and 0.4  $\mu$ m, respectively. The after filter effectively retains aerosolized drug in the particle size range up to 0.4  $\mu$ m. Connect the cascade impactor into the control system specified in [Figure 5](#). Omit Stage 6 and Stage 7 from the impactor if the test flow rate, Qout, used during testing for Delivered-Dose Uniformity was greater than or equal to 60 L per minute. To ensure efficient particle capture, coat the particle collection surface of each stage with glycerol, silicone oil, or other suitable liquid typically deposited from a volatile solvent, unless it has been demonstrated to be unnecessary. Assemble the impactor as described in the manufacturer's literature with an after filter below the final stage to capture any fine particles that otherwise would escape from the device. Place an appropriate volume (up to 10 mL) of an appropriate solvent into the preseparator, or coat the particle collection surfaces of the preseparator to prevent re-entrainment of impacted particles. [Caution—Some solvents form flammable vapor-air mixtures that may be ignited during passage through a vacuum pump. Take appropriate precautions (alternative solvents, use of vapor traps, minimal pump operating times, etc.) to ensure operator safety during testing.] Attach a molded mouthpiece adapter to the end of the induction port to produce an airtight seal between the inhaler mouthpiece and the induction port. Use a mouthpiece adapter that ensures that the tip of the inhaler mouthpiece is flush with the open end of the induction port. Ensure that the various stages of the cascade impactor are connected with airtight seals to prevent leaks.

Turn on the vacuum pump, open the two-way solenoid valve, and calibrate the airflow through the system as follows. Prime or load the dry powder inhaler with powder for inhalation according to the labeled instructions. With the vacuum pump running and the two-way solenoid valve closed, insert the inhaler mouthpiece, held horizontally, into the induction port mouthpiece adapter. Once the inhaler is positioned, discharge the powder into the apparatus by activating the timer and opening the two-way solenoid valve for the required duration, T  $\pm 5\%$ , as determined during testing for Delivered-Dose Uniformity. After the two-way solenoid valve has closed, remove the inhaler from the mouthpiece adapter. If additional doses are required for the sample, reload the inhaler according to the labeled instructions, reinsert the mouthpiece into the mouthpiece adapter, and repeat the operation until the required number of doses have been discharged. After discharge of the last dose, remove the inhaler from the mouthpiece adapter, and switch off the vacuum pump.

Carefully disassemble the apparatus. Using a suitable solvent, rinse the drug from the mouthpiece adapter, induction port, and preseparator, and quantitatively dilute to an appropriate volume. Rinse the drug from each stage, and the impaction plate immediately below, into appropriately sized flasks. Quantitatively dilute each flask to an appropriate volume. Using the method of analysis specified in the individual monograph, determine the mass of drug collected in each of the samples. The aerodynamic cutoff diameters of the individual stages of this device, in the airflow range between 30 and 100 L per minute, are currently not well established. Do not use the formula in Equation 1 to calculate cutoff diameters.

Procedure— Proceed as directed in the General Procedure under Apparatus 2, except to use Apparatus 3.

#### Apparatus 4 for Dry Powder Inhalers—

note—Apparatus 4, the multistage liquid impinger, has a small number of stages and is used extensively outside the USA. It is provided here for the benefit of users in countries other than the USA.

Design— The design and assembly of Apparatus 4 are shown in [Figs. 8, 8a, and 8b<sup>4</sup>](#). The induction port, used to connect the device to an inhaler, is shown in [Fig. 4a](#). The device is a multi-stage liquid impinger consisting of impaction Stages 1, 2, 3, and 4 and an integral after filter (Stage 5). The collection stages of the liquid impinger (see [Fig. 8](#) and [Table 4](#)) are kept moist, unlike those of traditional impactors, such as Apparatus 1, 2, 3, 5, and 6; wetting may produce an effect similar to coating the stages of Apparatus 2, 3, 5, and 6 at certain flow rates, although this should be confirmed by demonstrating control over re-entrainment as described earlier. An impaction stage comprises an upper horizontal metal partition wall (B) through which a metal inlet jet tube (A) with its impaction plate (D) is protruding; a glass cylinder (E) with sampling port (F), forming the vertical wall of the stage; and a lower horizontal metal partition wall (G) through which a jet tube (H) connects to the lower stage. The tube into Stage 4 (U) ends in a multi-jet arrangement. The impaction plate (D) is secured in a metal frame (J), which is fastened by two wires (K) to a sleeve (L) secured on the jet tube (C). For more detail of the jet tube and impaction plate, see [Fig. 8a](#). The horizontal plane of the collection plate is perpendicular to the axis of the jet tube and centrally aligned. The upper surface of the impaction plate is slightly raised above the edge of the metal frame. A recess around the perimeter of the horizontal partition wall guides the position of the glass cylinder. The glass cylinders are sealed against the horizontal partition walls with gaskets (M) and clamped together by six bolts (N). The sampling ports are sealed by stoppers. The bottom side of the lower partition wall of Stage 4 has a concentric protrusion fitted with a rubber O-ring (P) that seals against the edge of a filter placed in the filter holder. The filter holder (R) is a basin with a concentric recess in which a perforated filter support (S) is flush-fitted. The filter holder is designed for 76-mm diameter filters. The whole impaction stage assembly is clamped onto the filter holder by two snap locks (T). The impinger is equipped with an induction port ([Fig. 4a](#)) that fits onto the Stage 1 inlet jet tube. A rubber O-ring on the jet tube provides an airtight connection to the induction port. An elastomeric mouthpiece adapter to fit the inhaler being tested provides an airtight seal between the inhaler and the induction port.

At a volumetric airflow rate of 60 L per minute (the nominal flow rate,  $Q_n$ ), the cutoff aerodynamic diameters  $D_{50,Q_n}$  of Stages 1 to 4 are 13.0, 6.8, 3.1, and 1.7  $\mu\text{m}$ , respectively. The after filter effectively retains aerosolized drug in the particle size range up to 1.7  $\mu\text{m}$ . Ensure that Apparatus 4 is clean and free of drug solution from any previous tests. Place a 76-mm diameter filter in the filter stage, and assemble the apparatus. Use a low pressure filter capable of quantitatively collecting the passing drug aerosol, which also allows a quantitative recovery of the collected drug. Set up Apparatus 4 using the control system as specified in [Figure 5](#). Attach the induction port ([Figure 4a](#)) and mouthpiece adapter to produce an airtight seal between the inhaler mouthpiece and the induction port. Use a mouthpiece adapter that ensures that the tip of the inhaler mouthpiece is flush with the open end of the induction port. Ensure that the various stages of the apparatus are connected with airtight seals to prevent leaks. Turn on the vacuum pump, open the two-way solenoid valve, and calibrate the airflow through the system as follows. Connect a flowmeter, calibrated for the volumetric flow rate leaving the meter, to the induction port. Adjust the flow-control valve to achieve a steady flow through the system at the required rate,  $Q_{out}$ , so that  $Q_{out}$  is within  $\pm 5\%$  of the value determined during testing for Delivered-Dose Uniformity. Ensure that critical flow occurs in the flow-control valve, at the value of  $Q_{out}$  to be used during testing, using the following procedure. With the inhaler in place, and the intended flow running, measure the absolute pressure on both sides of the flow-control valve ( $P_2$  and  $P_3$  in [Figure 5](#)). A ratio of  $P_3/P_2 \leq 0.5$  indicates critical flow. Switch to a more powerful pump, and remeasure the test flow rate if  $P_3/P_2 > 0.5$ . Adjust the timer controlling the operation of the two-way solenoid valve so that it opens that valve for the same duration,  $T$ , as used during testing for Delivered-Dose Uniformity. Dispense 20 mL of a solvent, capable of dissolving the drug, into each of the four upper stages of Apparatus 4, and replace the stoppers. [Caution—Some solvents form flammable vapor-air mixtures that may be ignited during passage through a vacuum pump. Take appropriate precautions (alternative solvents, use of vapor traps, minimal pump operating times, etc.) to ensure operator safety during testing.] Tilt the apparatus to wet the stoppers, thereby neutralizing their electrostatic charge. Adjust the timer controlling the operation of the two-way solenoid valve so that it opens the valve for the same duration,  $T$ , as used during testing for Delivered-Dose Uniformity. Prime or load the dry powder inhaler with powder for inhalation according to the labeled instructions. With the vacuum pump running and the two-way solenoid valve closed, insert the inhaler mouthpiece, held horizontally, into the induction port mouthpiece adapter. Discharge the powder into the apparatus by activating the timer and opening the two-way solenoid valve for the required duration,  $T \pm 5\%$ . After the two-way solenoid valve has closed, remove the inhaler from the mouthpiece adapter. If additional doses are required for the sample, reload the inhaler according to the labeled instructions, reinsert the mouthpiece into the mouthpiece adapter, and repeat the operation until the required number of doses have been discharged. After discharge of the last dose, switch off the vacuum pump.

Dismantle the filter stage of Apparatus 4. Carefully remove the filter, and extract the drug with solvent. Rinse the mouthpiece adapter and induction port with a suitable solvent, and quantitatively dilute to an appropriate volume. Rinse the inside of the inlet jet tube to Stage 1 ([Figure 8](#)), allowing the solvent to flow into the stage. Rinse the drug from the inner walls and the collection plate of each of the four upper stages of the apparatus, into the solution in the respective stage, by tilting and rotating the apparatus, while ensuring that no liquid transfer occurs between the stages. Using the method of analysis specified in the individual monograph, determine the mass of drug collected in each of the six volumes of solvent. Ensure that the method corrects for possible evaporation of the solvent during the test. This may involve the use of an internal standard (of known original concentration in the solvent and assayed at the same time as the drug) or the quantitative transfer of the liquid contents from each of the stages, followed by dilution to a known volume. Determine the cutoff diameters of each of the individual stages of the impactor, at the value of  $Q = Q_{out}$  employed in the test by the formula:

$$D_{50,Q} = D_{50,Q_n} (Q_n / Q)^{1/2}$$

where  $D_{50,Q}$  is the cutoff diameter at the flow rate,  $Q$ , employed in the test, and the subscript,  $n$ , refers to the nominal values determined when  $Q_n$  equals 60 L of air per minute. Thus, when  $Q$  equals 40 L of air per minute, the cutoff diameter of Stage 2 is given by the formula:

$$D_{50,40LPM} = 6.8 \mu\text{m} \times (60/40)^{1/2} = 8.3 \mu\text{m}.$$

Procedure— Proceed as directed in the General Procedure under Apparatus 2, except to use Apparatus 4.

#### Apparatus 5 for Dry Powder Inhalers—

Design— The design and assembly of Apparatus 5<sup>5</sup> are shown in [Figures 9, 9a, 9b, 9c](#), and [9d](#). The induction port, used to connect the device to an inhaler, is shown in [Figure 4a](#). The device is a cascade impactor with seven stages and a micro-orifice collector (MOC). Over the design flow-rate range of 30 to 100 L per minute, the 50% efficiency cut-off diameters of the stages ( $D_{50}$  values) range between 0.24  $\mu\text{m}$  to 11.7  $\mu\text{m}$ , evenly spaced on a logarithmic scale. In the design flow-rate range, there are always at least five stages with  $D_{50}$  values between 0.5  $\mu\text{m}$  and 6.5  $\mu\text{m}$ . The collection efficiency curves for each stage are sharp and minimize overlap between stages. Material may be aluminum, stainless steel, or other suitable material.

The impactor layout has removable impaction cups with all the cups in one plane ([Figures 9–9c](#)). There are three main sections to the impactor: the bottom frame that holds the impaction cups, the seal body that holds the jets, and the lid that contains the interstage passageways (shown in [Figures 9–9b](#)). Multiple nozzles are used at all but the first stage ([Figure 9c](#)). The flow passes through the impactor in a saw-tooth pattern.

Stage mensuration is performed periodically together with confirmation of other dimensions critical to the effective operation of the impactor. Critical dimensions are provided below in [Table 6](#).

Table 6. Critical Dimensions for Apparatus 5 and 6

Description	Dimension (mm)
Preseparator (dimension a—see <a href="#">Figure 9d</a> )	12.80 $\pm$ 0.05
Stage 1 <sup>1</sup> Nozzle diameter	14.30 $\pm$ 0.05
Stage 2 <sup>2</sup> Nozzle diameter	4.88 $\pm$ 0.04
Stage 3 <sup>3</sup> Nozzle diameter	2.185 $\pm$ 0.02
Stage 4 <sup>4</sup> Nozzle diameter	1.207 $\pm$ 0.01
Stage 5 <sup>5</sup> Nozzle diameter	0.608 $\pm$ 0.01
Stage 6 <sup>6</sup> Nozzle diameter	0.323 $\pm$ 0.01
Stage 7 <sup>7</sup> Nozzle diameter	0.206 $\pm$ 0.01
MOC <sup>1</sup>	approximately 0.070
Cup Depth (Dimension b—see <a href="#">Figure 9b</a> )	14.625 $\pm$ 0.10
Collection cup surface roughness	0.5 to 2 $\mu\text{m}$
Stage 1 Nozzle to seal body distance <sup>2</sup> —dimension c	0 $\pm$ 1.18
Stage 2 Nozzle to seal body distance <sup>2</sup> —dimension c	5.236 $\pm$ 0.736
Stage 3 Nozzle to seal body distance <sup>2</sup> —dimension c	8.445 $\pm$ 0.410
Stage 4 Nozzle to seal body distance <sup>2</sup> —dimension c	11.379 $\pm$ 0.237
Stage 5 Nozzle to seal body distance <sup>2</sup> —dimension c	13.176 $\pm$ 0.341
Stage 6 Nozzle to seal body distance <sup>2</sup> —dimension c	13.999 $\pm$ 0.071
Stage 7 Nozzle to seal body distance <sup>2</sup> —dimension c	14.000 $\pm$ 0.071
MOC Nozzle to seal body distance <sup>2</sup> —dimension c	14.429 – 14.571

<sup>1</sup> See [Figure 9c](#).

<sup>2</sup> See [Figure 9b](#).

In routine operation, the seal body and lid are held together as a single assembly. The impaction cups are accessible when this assembly is opened at the end of an inhaler test. The cups are held in a support tray, so that all cups can be removed from the impactor simultaneously by lifting out the tray.

An induction port with internal dimensions identical to those defined in [Figure 4a](#) is connected to the impactor inlet. When necessary, with dry powder inhalers, a preseparator can be added to avoid overloading the first stage. This preseparator connects between the induction port and the impactor. A suitable mouthpiece adapter is used to provide an airtight seal between the inhaler and the induction port.

At a volumetric airflow rate of 60 L per minute (the assigned reference flow rate for cutoff-diameter calculations,  $Q_n$ ), the cutoff-aerodynamic diameters  $D_{50,Q_n}$  of Stages 1 to 7 are 8.06, 4.46, 2.82, 1.66, 0.94, 0.55 and 0.34  $\mu\text{m}$ , respectively. The apparatus contains a terminal micro-orifice collector (MOC) that for most formulations may eliminate the need for a final filter as determined by method validation. The MOC is an impactor nozzle plate and collection cup. The nozzle plate contains, nominally, 4032 jets, each approximately 70  $\mu\text{m}$  in diameter. Most particles not captured on Stage 7 of the impactor will be captured on the cup surface below the MOC. (For impactors operated at 60 L per minute, the MOC is capable of collecting 80% of 0.14- $\mu\text{m}$  particles). For formulations with a significant fraction of particles not captured by the MOC, there is an optional filter holder that can replace the MOC or be placed downstream of the MOC containing a suitable after-filter (glass fiber is often suitable).

Procedure— Assemble the apparatus with the preseparator ([Figure 9d](#)), unless experiments have shown that its omission does not result in increased interstage drug losses (>5%) or particle re-entrainment, in which case the preseparator may be omitted.

Place cups into the apertures in the cup tray. To ensure efficient particle capture, coat the particle collection surface of each stage with glycerol, silicone oil, or other suitable liquid typically deposited from a volatile solvent, unless it has been demonstrated to be unnecessary. Insert the cup tray into the bottom frame, and lower into place. Close the impactor lid with the seal body attached, and operate the handle to lock the impactor together so that the system is airtight.

The preseparator may be assembled as follows: assemble the preseparator insert into the preseparator base; fit the preseparator base to the impactor inlet; add 15 mL of the solvent used for sample recovery to the central cup of the preseparator insert; place the preseparator body on top of this assembly; and close the two catches. [Caution—Some solvents form flammable vapor-air mixtures that may be ignited during passage through a vacuum pump. Take appropriate precautions (e.g., alternative solvents, use of vapor traps, minimal pump operating times, etc.) to ensure operator safety during testing.]

Connect an induction port with internal dimensions as defined in [Figure 4a](#) either to the impactor inlet or to the preseparator inlet atop the cascade impactor ([Figure 9d](#)). Place a suitable mouthpiece adapter in position at the end of the induction port so that the mouthpiece end of the inhaler, when inserted, lines up along the horizontal axis of the induction port. The front face of the inhaler mouthpiece is flush with the front face of the induction port, producing an airtight seal. When attached to the mouthpiece adapter, the inhaler should be positioned in the same orientation as intended for use. Connect the apparatus to a flow system according to the scheme specified in [Figure 5](#).

Unless otherwise prescribed, conduct the test at the flow rate used in the test for Delivered-Dose Uniformity drawing 4 L of air from the mouthpiece of the inhaler and through the apparatus. Connect a flowmeter to the induction port. Use a flowmeter calibrated for the volumetric flow leaving the meter, or calculate the volumetric flow leaving the meter ( $Q_{out}$ ) using the ideal gas law. For a meter calibrated for the entering volumetric flow ( $Q_{in}$ ), use the formula:

$$Q_{out} = Q_{in}P_0 / (P_0 - \Delta P)$$

where  $P_0$  is the atmospheric pressure and  $\Delta P$  is the pressure drop over the meter. Adjust the flow control valve to achieve steady flow through the system at the required rate,  $Q_{out}$  ( $\pm 5\%$ ). Ensure that critical flow occurs in the flow-control valve by the procedure described for Apparatus 2. Adjust the timer controlling the operation of the two-way solenoid valve so that it opens the valve for the same duration,  $T$ , as used during testing for Delivered-Dose Uniformity.

Prime or load the dry powder inhaler with powder for inhalation according to the labeled instructions. With the vacuum pump running and the two-way solenoid valve closed, insert the inhaler mouthpiece, held horizontally, into the induction port mouthpiece adapter. Discharge the powder into the apparatus by activating the timer and opening the two-way solenoid valve for the required duration,  $T$  ( $\pm 5\%$ ). After the two-way solenoid valve has closed, remove the inhaler from the mouthpiece adapter. If additional doses are required for the sample, reload the inhaler according to the labeled instructions, reinsert the mouthpiece into the mouthpiece adapter, and repeat the operation until the required number of doses have been discharged. After discharge of the last dose, switch off the vacuum pump.

Dismantle the apparatus, and recover drug for analysis as follows: remove the induction port and mouthpiece adapter from the preseparator and extract the drug into an aliquot of solvent; if used, remove the preseparator from the impactor, without spilling the solvent into the impactor; and recover the active ingredient from all inner surfaces.

Open the impactor by releasing the handle and lifting the lid. Remove the cup tray, with the collection cups, and recover the active ingredient from each cup into an aliquot of solvent. Using the method of analysis specified in the individual monograph, determine the mass of drug contained in each of the aliquots of solvent.

Determine the cutoff diameters of each of the individual stages of the impactor, at the value of  $Q = Q_{out}$  employed in the test by the formula:

$$D_{50,Q} = D_{50,Q_n} (Q_n / Q)^X, \quad (\text{Eq. 2})$$

where  $D_{50,Q}$  is the cutoff diameter at the flow rate,  $Q$ , employed in the test, and the subscript,  $n$ , refers to the nominal or reference value for  $Q_n = 60$  L of air per minute (see [Table 7](#)). The values for the exponent,  $x$ , are listed in [Table 7](#). Thus, when  $Q = 40$  L of air per minute, the cutoff diameter of Stage 2 is given by the formula:

$$D_{50,40LPM} = 4.46 \mu\text{m} \times (60/40)^{0.52} = 5.51 \mu\text{m}.$$

Analyze the data as directed under Data Analysis.

Table 7. Cutoff Aerodynamic Diameter for Stages of Apparatus 5 and 6

Use Eq. 2 to calculate $D_{50,Q}$ for flow rates, $Q$ , in the range 30 to 100 L per minute with $Q_n = 60$ L per minute.		
Stage	$D_{50,Q_n}$	$x$
1	8.06	0.54
2	4.46	0.52
3	2.82	0.50
4	1.66	0.47
5	0.94	0.53
6	0.55	0.60
7	0.34	0.67

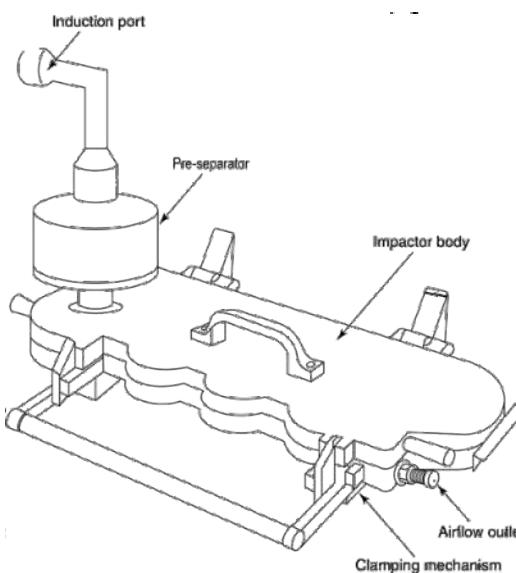

Fig. 9. Apparatus 5 (shown with the preseparator in place).

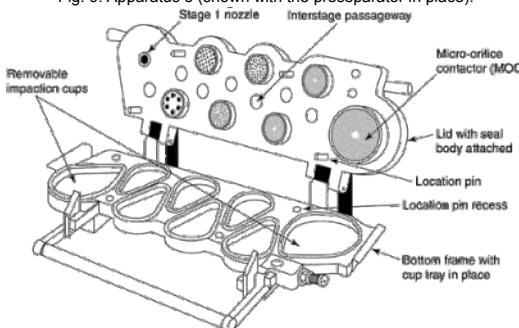

Fig. 9a. Components of Apparatus 5.

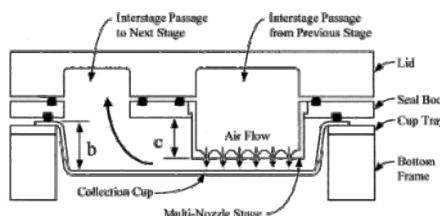

Fig. 9b. Layout of interstage passageways of Apparatus 5.

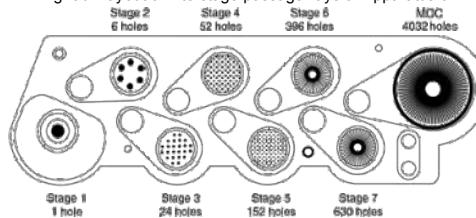

Fig. 9c. Nozzle configuration of Apparatus 5.

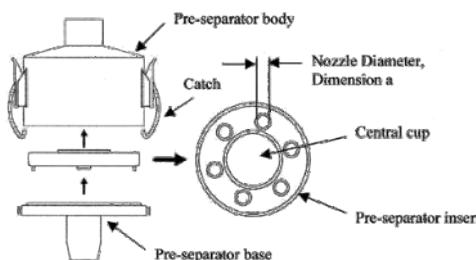

Fig. 9d. Pre-separator layout for Apparatus 5.

#### Apparatus 6 for Metered-Dose Inhalers—

Design— Apparatus 6 is identical to Apparatus 5 (Figures 9-9d), except that the preseparator is not to be used. Use this apparatus at a flow rate of 30 L per minute ( $\pm 5\%$ ), unless otherwise prescribed in the individual monograph.

Procedure— Assemble the apparatus without the preseparator. Place cups into the apertures in the cup tray. To ensure efficient particle capture, coat the particle collection surface of each stage with glycerol, silicone oil, or other suitable liquid typically deposited from a volatile solvent, unless it has been demonstrated to be unnecessary. Insert the cup tray into the

bottom frame, and lower into place. Close the impactor lid with seal body attached, and operate the handle to lock the impactor together so that the system is airtight. Connect a induction port with internal dimensions as defined in [Figure 4a](#) to the impactor inlet. Use a mouthpiece adapter that ensures that the tip of the inhaler mouthpiece is flush with the open end of the induction port. Turn on the vacuum pump to draw air through the cascade impactor, and calibrate the airflow through the system with an appropriate flowmeter attached to the open end of the induction port. Adjust the flow-control valve on the vacuum pump to achieve steady flow through the system at the required rate, and ensure that the airflow through the system is within  $\pm 5\%$  of this flow rate. Unless otherwise prescribed in the patient instructions, shake the inhaler for 5 seconds, and discharge one delivery to waste. With the vacuum pump running, insert the mouthpiece into the mouthpiece adapter, and immediately fire the minimum recommended dose into the cascade impactor. Keep the valve depressed for a duration sufficient to ensure that the dose has been completely discharged. If additional sprays are required for the sample, shake the inhaler, reinsert it into the mouthpiece adapter, and immediately fire the next minimum recommended dose.

Repeat until the required number of doses have been discharged. The number of minimum recommended doses discharged must be sufficient to ensure an accurate and precise determination of Aerodynamic Size Distribution. [note—The number of minimum recommended doses is typically not greater than 10.] After the last dose has been discharged, remove the inhaler from the mouthpiece adapter. Rinse the mouthpiece adapter and induction port with a suitable solvent, and dilute quantitatively to an appropriate volume.

Dismantle the apparatus, and recover the drug for analysis as follows: remove the induction port and mouthpiece adapter from the apparatus, and recover the deposited drug into an aliquot of solvent; open the impactor by releasing the handle and lifting the lid; remove the cup tray, with the collection cups; and extract the active ingredient in each cup into an aliquot of solvent. Using the method of analysis specified in the individual monograph, determine the quantity of active ingredient contained in each of the aliquots of solvent.

Determine the cutoff diameters of each of the individual stages of the impactor, at the value of Q employed in the test by using Eq. 2 with values obtained from [Table 7](#). Thus, when  $Q = 30 \text{ L of air per minute}$ , the cutoff diameter of Stage 2 is given by the formula:

$$D_{50,30\text{LPM}} = 4.46 \mu\text{m} \times (60/30)0.52 = 6.40 \mu\text{m}$$

To analyze the data, proceed as directed under Data Analysis.

#### Data Analysis

This section describes the data analysis required to define the Aerodynamic Size Distribution of the drug output from the test inhaler, after the use of Apparatus 1, 2, 3, 4, 5, or 6. Enter the data collected from Apparatus 1, 2, 3, 4, 5, or 6 in the table of mass summaries as shown in Table 8. Perform only those calculations specified in the individual monograph.

Table 8. Table of Mass Summaries for Analyses of Metered-Dose Inhalers and Dry Powder Inhalers

Mass	Apparatus 1		Apparatus 2		Apparatus 3 <sup>a</sup>		Apparatus 4 <sup>b</sup>		Apparatus 5 <sup>d</sup>		Apparatus 6 <sup>d</sup>

Stage 7 of impactor/impinger	A7	B7	—	—	A7	B7	—	—	A7	B7	A7	B7	
Filter	AF	BF	AF	BF	AF	BF	AF	BF	AF	BF	AF	BF	
Sums of Masses	$\Sigma A^e$	$\Sigma B^e$	$\Sigma A^e$	$\Sigma B^e$	$\Sigma A^e$	$\Sigma B^e$	$\Sigma A^e$	$\Sigma B^e$	$\Sigma A^e$	$\Sigma B^e$	$\Sigma A^e$	$\Sigma B^e$	

a Stages 6 and 7 are omitted from Apparatus 3 at airflow rates  $>60 \text{ L per minute}$ .

b Stage 5 of Apparatus 4 is the filter stage (see [Figure 8](#)).

c  $\Sigma A$  is the total drug mass recovered from the apparatus;  $\Sigma B$  is the mass of drug recovered from the impactor (Apparatus 1, 3, 5 and 6) or from the impactor stages beneath the uppermost stage (Apparatus 2 and 4).

d For Apparatus 5 and 6, values for the drug masses AF and BF refer to collections from the MOC, and/or the after-filter if used.

calculations

Fine Particle Dose and Fine Particle Fraction— Calculate the total mass,  $\Sigma A$ , of drug delivered from the mouthpiece of the inhaler into the apparatus. Then calculate the total mass, R, of drug found on the stages of the apparatus and the filter that captured the drug in the fine particle size range appropriate for the particular drug being tested. The Fine Particle Dose is calculated by the formula:

$$R/n$$

where R is as stated above, and n is the number of doses discharged during the test. The Fine Particle Fraction that would be delivered from the inhaler is then calculated by the formula:

$$R/\Sigma A.$$

Cumulative Percentage (Cum%) of Drug Mass Less Than Stated Aerodynamic Diameter— Construct [Table 9](#) by dividing the mass of drug on the filter stage by  $\Sigma B$  (see Table 8).

Multiply the quotient by 100, and enter this number as a percentage opposite the effective cutoff diameter of the stage immediately above it in the impactor or impinger stack. For Apparatus 2 or 4, use Equation 1 to calculate the stage cutoff diameters,  $D_{50,Q}$ , at the airflow rate, Q, employed during the test. For Apparatus 5 and 6, use Equation 2 with [Table 7](#). For Apparatus 1, use the cutoff diameters quoted by the manufacturer. For Apparatus 3, present the data as cumulative percentages of mass on and below the stated stage, and avoid assigning values to stage cutoff diameters.

Repeat the calculation for each of the stages in the impactor or impinger stack, in reverse numerical order (largest to smallest stage number). For each stage, calculate the cumulative percentage of mass less than the stated aerodynamic diameter by adding the percentage of the mass on that stage to the total percentage from the stages below and entering the value opposite the effective cutoff diameter of the stage above it in the stack. Thus, the percentage of drug on the filter can be seen to have aerodynamic diameters less than the cutoff diameter of the stage above the filter, and the percentage on the filter plus the percentage on the stage above have diameters less than the cutoff diameter of the stage above that, and so on. Repeat the calculation for each of the remaining stages in reverse numerical order (see [Table 9](#)).

Table 9. Cumulative Percentage (Cum%) of Mass Less than the Stated Aerodynamic Diameter

	Apparatus 1		Apparatus 2		Apparatus 3 <sup>a</sup>		Apparatus 4 <sup>b</sup>		Apparatus 5		Apparatus 6	
Mass	Cum% <sup>e</sup>	$D_{50,Q}^d$	Cum% <sup>e</sup>	$D_{50,Q}^d$	Cum% <sup>e</sup>	$D_{50,Q}^d$	Cum% <sup>e</sup>	$D_{50,Q}^d$	Cum% <sup>e</sup>	$D_{50,Q}^d$	Cum% <sup>e</sup>	$D_{50,Q}^d$
Filter	0.4	0.625	0.4	1.7	0.34	0.34						
Stage 7	b	0.7	—	—	b	0.7	—	—	b	0.55	b	0.55
Stage 6	c	1.1	—	—	c	1.1	—	—	c	0.94	c	0.94
Stage 5	d	2.1	b	1.25	d	2.1	—	—	d	1.66	d	1.66
Stage 4	e	3.3	c	2.5	e	3.3	b	3.1	e	2.82	e	2.82

Stage 3	f	4.7	d	5.0	f	4.7	c	6.8	f	4.46	f	4.46
Stage 2	g	5.8	100	10.0	g	5.8	100	13.0	g	8.06	g	8.06
Stage 1	h	9.0	—	—	h	9.0	—	—	—	—	—	—
Stage 0	100	—	—	—	100	—	—	—	100	—	100	—

a Stages 6 and 7 are omitted from Apparatus 3 at flow rates >60 L per minute; thus, values for b and c should be omitted for Apparatus 3, where necessary.

b The filter stage in Apparatus 4 is Stage 5 (see [Figure 8](#)).

c [(mass on stage /  $\Sigma$ B)  $\times 100$ ] % + (total% of  $\Sigma$ B from stages below).

d The 50% cutoff diameter of the stage immediately above that indicated (e.g., for Stage 4, enter the cutoff diameter for Stage 3; for Apparatus 2 or 4, calculate as D<sub>50,Q</sub> from Eq. 1; for Apparatus 5 or 6, calculate as D<sub>50,Q</sub> from Eq. 2 using [Table 7](#)). Values entered in the Table are correct for Apparatus 1, 2, 4, 5, and 6 only when used at 28.3, 60.0, 60.0, 60.0, and 60.0 L per minute, respectively.

e The D<sub>50</sub> values are only valid at a flow rate of 28.3 L per minute.

If necessary, and where appropriate, plot the percentage of mass less than the stated aerodynamic diameters, versus the aerodynamic diameter, D<sub>50,Q</sub>, on log probability paper.

Calculate the GSD by the equation:

$$GSD = \sqrt{\frac{\text{Size } X}{\text{Size } Y}}$$

Use these data and/or plot to determine values for MMAD and GSD etc., as appropriate and when necessary (see [Figure 10](#)).

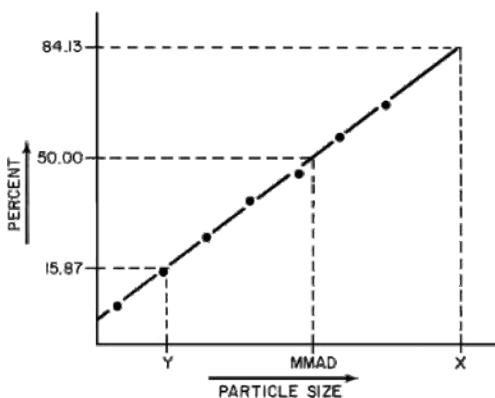

Fig. 10. Plot of cumulative percentage of mass less than stated aerodynamic diameter (probability scale) versus aerodynamic diameter (log scale).

1 A suitable cascade impactor is available as Model Mk II from Thermo-Electron, 27 Forge Parkway, Franklin, MA 02038. The impactor is used without the preseparator. The inhaler is connected to the impactor via the induction port, atop the entrance cone shown in [Figure 4](#). If an equivalent impactor is employed, the induction port in [Figure 4a](#) should be used, although the entrance cone ([Fig. 4b](#)) should be replaced with one to fit the impactor in question. Note that the internal surfaces of the induction port ([Fig. 4a](#)) are designed to fit flush with their counterparts in the entrance cone ([Fig. 4b](#)). This design avoids aerosol capture at the junction of the two pipes.

2 The cascade impactor is available as the Model 160 Marple-Miller Impactor from MSP Corporation, Minneapolis, MN. The inhaler should be connected to the impactor via the induction port, shown in [Figure 4a](#).

3 The cascade impactor is available as the Andersen 1ACFM Non-Viable Cascade Impactor (Mark II) from Thermo-Electron, 27 Forge Parkway, Franklin, MA 02038. The impactor is used with the preseparator.

4 The five-stage impinger is available from Copley Instruments, plc, Nottingham, UK. The inhaler should be connected to the impinger via the induction port, shown in [Fig. 4](#) and [Fig. 4a](#).

5 The cascade impactor is available as the Next Generation Pharmaceutical Impactor from MSP Corporation, Minneapolis, MN.

611 ALCOHOL DETERMINATION

#### METHOD I—DISTILLATION METHOD

Method I is to be used for the determination of alcohol, unless otherwise specified in the individual monograph. It is suitable for examining most fluidextracts and tinctures, provided the capacity of the distilling flask is sufficient (commonly two to four times the volume of the liquid to be heated) and the rate of distillation is such that clear distillates are produced. Cloudy distillates may be clarified by agitation with talc, or with calcium carbonate, and filtered, after which the temperature of the filtrate is adjusted and the alcohol content determined from the specific gravity. During all manipulations, take precautions to minimize the loss of alcohol by evaporation.

Treat liquids that froth to a troublesome extent during distillation by rendering them strongly acidic with phosphoric, sulfuric, or tannic acid, or treat with a slight excess of calcium

chloride solution or with a small amount of paraffin or silicone oil before starting the distillation.

Prevent bumping during distillation by adding porous chips of insoluble material such as silicon carbide, or beads.

For Liquids Presumed to Contain 30% of Alcohol or Less— By means of a pipet, transfer to a suitable distilling apparatus not less than 25 mL of the liquid in which the alcohol is to be determined, and note the temperature at which the volume was measured. Add an equal volume of water, distill, and collect a volume of distillate about 2 mL less than the volume taken of the original test liquid, adjust to the temperature at which the original test liquid was measured, add sufficient water to measure exactly the original volume of the test liquid, and mix. The distillate is clear or not more than slightly cloudy, and does not contain more than traces of volatile substances other than alcohol and water. Determine the specific gravity of the liquid at 25°, as directed under [Specific Gravity](#) 841, using this result to ascertain the percentage, by volume, of C2H5OH contained in the liquid examined by reference to the Alcoholometric Table in the section Reference Tables.

For Liquids Presumed to Contain More Than 30% of Alcohol— Proceed as directed in the foregoing paragraph, except to do the following: dilute the specimen with about twice its volume of water, collect a volume of distillate about 2 mL less than twice the volume of the original test liquid, bring to the temperature at which the original liquid was measured, add sufficient water to measure exactly twice the original volume of the test liquid, mix, and determine its specific gravity. The proportion of C2H5OH, by volume, in this distillate, as ascertained from its specific gravity, equals one-half that in the liquid examined.

#### Special Treatment—

volatile acids and bases— Render preparations containing volatile bases slightly acidic with diluted sulfuric acid before distilling. If volatile acids are present, render the preparation slightly alkaline with [sodium hydroxide TS](#).

glycerin— To liquids that contain glycerin add sufficient water so that the residue, after distillation, contains not less than 50% of water.

iodine— Treat all solutions containing free iodine with powdered zinc before the distillation, or decolorize with just sufficient sodium thiosulfate solution (1 in 10), followed by a few drops of [sodium hydroxide TS](#).

other volatile substances— Spirits, elixirs, tinctures, and similar preparations that contain appreciable proportions of volatile materials other than alcohol and water, such as volatile oils, chloroform, ether, camphor, etc., require special treatment, as follows:

For Liquids Presumed to Contain 50% of Alcohol or Less— Mix 25 mL of the specimen under examination, accurately measured, with about an equal volume of water in a separator. Saturate this mixture with sodium chloride, then add 25 mL of solvent hexane, and shake the mixture to extract the interfering volatile ingredients. Draw off the separated, lower layer into a second separator, and repeat the extraction twice with two further 25-mL portions of solvent hexane. Extract the combined solvent hexane solutions with three 10-mL portions of a saturated solution of sodium chloride. Combine the saline solutions, and distill in the usual manner, collecting a volume of distillate having a simple ratio to the volume of the original specimen.

For Liquids Presumed to Contain More Than 50% of Alcohol— Adjust the specimen under examination to a concentration of approximately 25% of alcohol by diluting it with water, then proceed as directed in For Liquids Presumed to Contain 50% of Alcohol or Less, beginning with "Saturate this mixture with sodium chloride."

In preparing Collodion or Flexible Collodion for distillation, use water in place of the saturated solution of sodium chloride directed above.

If volatile oils are present in small proportions only, and a cloudy distillate is obtained, the solvent hexane treatment not having been employed, the distillate may be clarified and rendered suitable for the specific gravity determination by shaking it with about one-fifth its volume of solvent hexane, or by filtering it through a thin layer of talc.

#### Method II—Gas Chromatographic Method

Use Method IIa when Method II is specified in the individual monograph. For a discussion of the principles upon which it is based, see Gas Chromatography under [Chromatography](#) 621.

USP Reference Standards— USP Alcohol Determination—Acetonitrile RS. USP Alcohol Determination—Alcohol RS.

#### Method IIa

Apparatus— Under typical conditions, use a gas chromatograph equipped with a flame-ionization detector and a 4-mm × 1.8-m glass column packed with 100- to 120-mesh chromatographic column packing support S3, using nitrogen or helium as the carrier. Prior to use, condition the column overnight at 235° with a slow flow of carrier gas. The column temperature is maintained at 120°, and the injection port and detector temperatures are maintained at 210°. Adjust the carrier flow and temperature so that acetonitrile, the internal standard, elutes in 5 to 10 minutes.

#### Solutions—

Test Stock Preparation— Dilute the specimen under examination stepwise with water to obtain a solution containing approximately 2% (v/v) of alcohol.

Test Preparation— Pipet 5 mL each of the Test Stock Preparation and the USP Alcohol Determination—Acetonitrile RS [note—Alternatively, a 2% aqueous solution of acetonitrile of suitable quality may be used as the internal standard solution] into a 50-mL volumetric flask, dilute with water to volume, and mix.

Standard Preparation— Pipet 5 mL each of the USP Alcohol Determination—Alcohol RS and the USP Alcohol Determination—Acetonitrile RS [note—Alternatively, a 2% aqueous solution of acetonitrile of suitable quality may be used as the internal standard solution] into a 50-mL volumetric flask, dilute with water to volume, and mix.

Procedure— Inject about 5 µL each of the Test Preparation and the Standard Preparation, in duplicate, into the gas chromatograph, record the chromatograms, and determine the peak response ratios. Calculate the percentage of alcohol (v/v) in the specimen under test according to the formula:

$$CD(RU / RS)$$

in which C is the labeled concentration of USP Alcohol Determination—Alcohol RS; D is the dilution factor (the ratio of the volume of the Test Stock Preparation to the volume of the specimen taken); and RU and RS are the peak response ratios obtained from the Test Preparation and the Standard Preparation, respectively.

System Suitability Test— In a suitable chromatogram, the resolution factor, R, is not less than 2; the tailing factor of the alcohol peak is not greater than 2.0; and six replicate injections of the Standard Preparation show a relative standard deviation of not more than 2.0% in the ratio of the peak of alcohol to the peak of the internal standard.

#### Method IIb

Apparatus— The gas chromatograph is equipped with a split injection port with a split ratio of 5:1, a flame-ionization detector, and a 0.53-mm × 30-m capillary column coated with a 3.0-µm film of phase G43. Helium is used as the carrier gas at a linear velocity of 34.0 cm per second. The chromatograph is programmed to maintain the column temperature at 50° for 5 minutes, then to increase the temperature at a rate of 10° per minute to 200°, and maintain at this temperature for 4 minutes. The injection port temperature is maintained at 210° and the detector temperature at 280°.

#### Solutions—

Test Stock Preparation— Dilute the specimen under examination stepwise with water to obtain a solution containing approximately 2% (v/v) of alcohol.

Test Preparation— Pipet 5 mL each of the Test Stock Preparation and the USP Alcohol Determination—Acetonitrile RS [note—Alternatively, a 2% aqueous solution of acetonitrile of suitable quality may be used as the internal standard solution] into a 25-mL volumetric flask, dilute with water to volume, and mix.

Standard Preparation— Pipet 5 mL each of the USP Alcohol Determination—Alcohol RS and the USP Alcohol Determination—Acetonitrile RS [note—Alternatively, a 2% aqueous solution of acetonitrile of suitable quality may be used as the internal standard solution] into a 25-mL volumetric flask, dilute with water to volume, and mix.

Procedure— Inject about 0.2 to 0.5 µL each of the Test Preparation and the Standard Preparation, in duplicate, into the gas chromatograph, record the chromatograms, and determine the peak response ratios. Calculate the percentage of alcohol (v/v) in the specimen under test according to the formula:

$$CD(RU / RS)$$

... which C is the labeled concentration of USP Alcohol Determination—Alcohol RS; D is the dilution factor (the ratio of the volume of the Test Stock Preparation to the volume of the specimen taken); and RU and RS are the peak response ratios obtained from the Test Preparation and the Standard Preparation, respectively.

System Suitability Test— In a suitable chromatogram, the resolution factor, R, between alcohol and the internal standard is not less than 4; the tailing factor of the alcohol peak is not greater than 2.0; and six replicate injections of the Standard Preparation show a relative standard deviation of not more than 4.0% in the ratio of the peak of alcohol to the peak of the internal standard.

Auxiliary Information— Please [check your question in the FAQs](#) before contacting USP.

#### 616 BULK DENSITY AND TAPPED DENSITY

The bulk density of a solid is often very difficult to measure since the slightest disturbance of the bed may result in a new bulk density. Moreover, it is clear that the bulking properties of a powder are dependent on the "history" of the powder (e.g., how it was handled), and that it can be packed to have a range of bulk densities. Thus, it is essential in reporting bulk density to specify how the determination was made.

Because the interparticulate interactions that influence the bulking properties of a powder are also the interactions that interfere with powder flow, a comparison of the bulk and tapped densities can give a measure of the relative importance of these interactions in a given powder. Such a comparison is often used as an index of the ability of the powder to flow. The bulk density often is the bulk density of the powder "as poured" or as passively filled into a measuring vessel. The tapped density is a limiting density attained after "tapping down," usually in a device that lifts and drops a volumetric measuring cylinder containing the powder a fixed distance.

#### BULK DENSITY

Bulk density is determined by measuring the volume of a known mass of powder sample that has been passed through a screen into a graduated cylinder (Method I) or through a volume-measuring apparatus into a cup (Method II).

##### Method I—Measurement in a Graduated Cylinder

Procedure— Unless otherwise specified, pass a quantity of material sufficient to complete the test through a 1.00-mm (No. 18) screen to break up agglomerates that may have formed during storage. Into a dry 250-mL cylinder introduce, without compacting, approximately 100 g of test sample, M, weighed with 0.1% accuracy. If it is not possible to use 100 g, the amount of the test sample and the volume of the cylinder may be modified and the test conditions specified with the results. Select a sample mass having an untapped apparent volume of 150 to 250 mL. A 100-mL cylinder is used for apparent volumes between 50 mL and 100 mL. Carefully level the powder without compacting, if necessary, and read the unsettled apparent volume,  $V_0$ , to the nearest graduated unit. Calculate the bulk density, in g per mL<sup>1</sup>, by the formula:

$$(M) / (V_0)$$

Generally replicate determinations are desirable for the determination of this property.

##### Method II—Measurement in a Volumeter

The apparatus ([Fig. 1](#)),

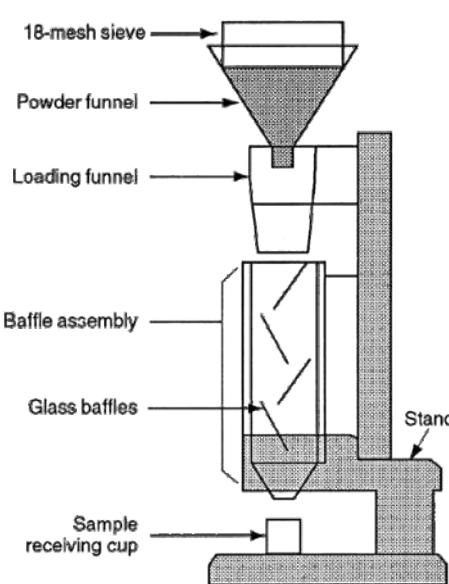

Fig. 1. Scott Volumeter.

conforming to the dimensions in ASTM B 329-90 (Scott Volumeter)<sup>2</sup>, consists of a top funnel fitted with a 1.00-mm (No. 18) screen or the screen opening specified in the individual monograph. The funnel is mounted over a baffle box containing four glass baffle plates over which the powder slides and bounces as it passes. At the bottom of the baffle box is a funnel that collects the powder and allows it to pour into a cup of specified capacity mounted directly below it. The cup may be cylindrical ( $25.00 \pm 0.05$  mL volume with an inside diameter of  $30.00 \pm 2.00$  mm) or a square ( $16.39 \pm 0.05$  mL volume with inside dimensions of  $25.4 \pm 0.076$  mm).

Procedure— Allow an excess of powder to flow through the apparatus into the sample receiving cup until it overflows, using a minimum of 25 cm<sup>3</sup> of powder with the square cup and 35 cm<sup>3</sup> of powder with the cylindrical cup. Carefully scrape excess powder from the top of the cup by smoothly moving the edge of the blade of a spatula perpendicular to and in contact with the top surface of the cup, taking care to keep the spatula perpendicular to prevent packing or removal of powder from the cup. Remove any material from the sides of the cup, and determine the weight, M, of the powder to the nearest 0.1%. Calculate the bulk density, in g per mL, by the formula:

$$(M) / (V_0)$$

in which  $V_0$  is the volume, in mL, of the cup. Generally replicate determinations are desirable for the determination of this property.

#### TAPPED DENSITY

Tapped density is achieved by mechanically tapping a measuring cylinder containing a powder sample. After observing the initial volume, the cylinder is mechanically tapped, and volume readings are taken until little further volume change is observed. The mechanical tapping is achieved by raising the cylinder and allowing it to drop under its own weight a specified distance by either of two methods as described below. Devices that rotate the cylinder during tapping may be preferred to minimize any possible separation of the mass during tapping down.

##### Method I

Procedure— Unless otherwise specified, pass a quantity of material sufficient to complete the test through a 1.00-mm (No. 18) screen to break up agglomerates that may have formed during storage. Into a dry 250-mL glass graduated cylinder (readable to 2 mL) weighing  $220 \pm 44$  g and mounted on a holder weighing  $450 \pm 10$  g introduce, without compacting, approximately 100 g of test sample, M, weighed with 0.1% accuracy. If it is not possible to use 100 g, the amount of the test sample may be reduced and the volume of the cylinder may be modified by using a suitable 100-mL graduated cylinder (readable to 1 mL) weighing  $130 \pm 16$  g and mounted on a holder weighing  $240 \pm 12$  g. The modified test conditions are specified with the results. Carefully level the powder without compacting, if necessary, and read the unsettled apparent volume,  $V_0$ , to the nearest graduated unit.

Mechanically tap the cylinder containing the sample by raising the cylinder and allowing it to drop under its own weight using a suitable mechanical tapped density tester that provides a fixed drop of  $14 \pm 2$  mm at a nominal rate of 300 drops per minute. Unless otherwise specified, tap the cylinder 500 times initially and measure the tapped volume,  $V_a$ , to the nearest graduated unit. Repeat the tapping an additional 750 times and measure the tapped volume,  $V_b$ , to the nearest graduated unit. [note—Fewer taps may be appropriate, if validated, for some powders.] If the difference between the two volumes is less than 2%,  $V_b$  is the final tapped volume,  $V_f$ . Repeat in increments of 1250 taps, as needed, until the difference between succeeding measurements is less than 2%. Calculate the tapped density, in g per mL, by the formula:

$$(M) / (V_f)$$

Generally replicate determinations are desirable for the determination of this property.

##### Method II

Proceed as directed under Method I except that a suitable mechanical tapped density tester that provides a fixed drop of 3 mm ( $\pm 10\%$ ) at a nominal rate of 250 drops per minute is used.

#### MEASURES OF POWDER COMPRESSIBILITY

The Compressibility Index and Hausner Ratio are measures of the propensity of a powder to be compressed. As such, they are measures of the relative importance of interparticulate interactions. In a free-flowing powder, such interactions are generally less significant, and the bulk and tapped densities will be closer in value. For poorer flowing materials, there are frequently greater interparticle interactions, and a greater difference between the bulk and tapped densities will be observed. These differences are reflected in the Compressibility Index and the Hausner Ratio.

Compressibility Index— Calculate by the formula:

$$\frac{100(V_o - V_f)}{V_o}$$

Hausner Ratio— Calculate by the formula:

$$\frac{V_o}{V_f}$$

1 The density of solids normally is expressed in g per cm<sup>3</sup> and that of liquids is normally expressed in g per mL; however, because powder volumes are measured in cylinders graduated in mL, bulk and tapped densities will be expressed in g per mL. By definition, the mL and the cm<sup>3</sup> are equivalent volumes.

2 Apparatus may be purchased from scientific supply companies and is usually described as a "Scott, Schaeffer and White Paint Pigment Volumeter."

Auxiliary Information— Please [check for your question in the FAQs](#) before contacting USP.

Topic/Question	Contact	Expert Committee

## INTRODUCTION

This chapter defines the terms and procedures used in chromatography and provides general information. Specific requirements for chromatographic procedures for drug substances and dosage forms, including adsorbent and developing solvents, are given in the individual monographs.

Chromatography is defined as a procedure by which solutes are separated by a dynamic differential migration process in a system consisting of two or more phases, one of which moves continuously in a given direction and in which the individual substances exhibit different mobilities by reason of differences in adsorption, partition, solubility, vapor pressure, molecular size, or ionic charge density. The individual substances thus separated can be identified or determined by analytical procedures.

The general chromatographic technique requires that a solute undergo distribution between two phases, one of them fixed (stationary phase), the other moving (mobile phase). It is the mobile phase that transfers the solute through the medium until it eventually emerges separated from other solutes that are eluted earlier or later. Generally, the solute is transported through the separation medium by means of a flowing stream of a liquid or a gaseous solvent known as the "eluent." The stationary phase may act through adsorption, as in the case of adsorbents such as activated alumina and silica gel, or it may act by dissolving the solute, thus partitioning the latter between the stationary and mobile phases. In the latter process, a liquid coated onto an inert support, or chemically bonded onto silica gel, or directly onto the wall of a fused silica capillary, serves as the stationary phase. Partitioning is the predominant mechanism of separation in gas-liquid chromatography, paper chromatography, in forms of column chromatography, and in thin-layer chromatography designated as liquid-liquid chromatography. In practice, separations frequently result from a combination of adsorption and partitioning effects. Other separation principles include ion exchange, ion-pair formation, size exclusion, hydrophobic interaction, and chiral recognition.

The types of chromatography useful in qualitative and quantitative analysis that are employed in the USP procedures are column, gas, paper, thin-layer, (including high-performance thin-layer chromatography), and pressurized liquid chromatography (commonly called high-pressure or high-performance liquid chromatography). Paper and thin-layer chromatography are ordinarily more useful for purposes of identification, because of their convenience and simplicity. Column chromatography offers a wider choice of stationary phases and is useful for the separation of individual compounds, in quantity, from mixtures. Modern high-performance thin-layer chromatography, gas chromatography, and pressurized liquid chromatography require more elaborate apparatus but usually provide high resolution and identify and quantitate very small amounts of material.

**Use of Reference Substances in Identity Tests**— In paper and thin-layer chromatography, the ratio of the distance (this distance being measured to the point of maximum intensity of the spot or zone) traveled on the medium by a given compound to the distance traveled by the front of the mobile phase, from the point of application of the test substance, is designated as the RF value of the compound. The ratio between the distances traveled by a given compound and a reference substance is the RR value. RF values vary with the experimental conditions, and thus identification is best accomplished where an authentic specimen of the compound in question is used as a reference substance on the same chromatogram.

For this purpose, chromatograms are prepared by applying on the thin-layer adsorbent or on the paper in a straight line, parallel to the edge of the chromatographic plate or paper, solutions of the substance to be identified, the authentic specimen, and a mixture of nearly equal amounts of the substance to be identified and the authentic specimen. Each sample application contains approximately the same quantity by weight of material to be chromatographed. If the substance to be identified and the authentic specimen are identical, all chromatograms agree in color and RF value and the mixed chromatogram yields a single spot; i.e., RR is 1.0.

**Location and Identification of Components**— The spots produced by paper or thin-layer chromatography may be located by: (1) direct inspection if the compounds are visible under white or either short-wavelength (254 nm) or long-wavelength (360 nm) UV light, (2) inspection in white or UV light after treatment with reagents that will make the spots visible (reagents are most conveniently applied with an atomizer), (3) use of a Geiger-Müller counter or autoradiographic techniques in the case of the presence of radioactive substances, or (4) evidence resulting from stimulation or inhibition of bacterial growth by the placing of removed portions of the adsorbent and substance on inoculated media.

In open-column chromatography, in pressurized liquid chromatography performed under conditions of constant flow rate, and in gas chromatography, the retention time, *t*, defined as the time elapsed between sample injection and appearance of the peak concentration of the eluted sample zone, may be used as a parameter of identification. Solutions of the substance to be identified or derivatives thereof, of the reference compound, and of a mixture of equal amounts of these two are chromatographed successively on the same column under the same chromatographic conditions. Only one peak should be observed for the mixture. The ratio of the retention times of the test substance, the reference compound, and a mixture of these, to the retention time of an internal standard is called the relative retention time RR and is also used frequently as a parameter of identification.

The deviations of RR, RF, or *t* values measured for the test substance from the values obtained for the reference compound and mixture should not exceed the reliability estimates determined statistically from replicate assays of the reference compound.

Chromatographic identification by these methods under given conditions strongly indicates identity but does not constitute definitive identification. Coincidence of identity parameters under three to six different sets of chromatographic conditions (temperatures, column packings, adsorbents, eluants, developing solvents, various chemical derivatives, etc.) increases the probability that the test and reference substances are identical. However, many isomeric compounds cannot be separated. Specific and pertinent chemical, spectroscopic, or physicochemical identification of the eluted component combined with chromatographic identity is the most valid criterion of identification. For this purpose, the individual components separated by chromatography may be collected for further identification.

## PAPER CHROMATOGRAPHY

In paper chromatography the adsorbent is a sheet of paper of suitable texture and thickness. Chromatographic separation may proceed through the action of a single liquid phase in a process analogous to adsorption chromatography in columns. Since the natural water content of the paper, or selective imbibition of a hydrophilic component of the liquid phase by the paper fibers, may be regarded as a stationary phase, a partitioning mechanism may contribute significantly to the separation.

Alternatively, a two-phase system may be used. The paper is impregnated with one of the phases, which then remains stationary (usually the more polar phase in the case of unmodified paper). The chromatogram is developed by slow passage of the other, mobile phase over the sheet. Development may be ascending, in which case the solvent is carried up the paper by capillary forces, or descending, in which case the solvent flow is also assisted by gravitational force.

Differences in the value of RF have been reported where chromatograms developed in the direction of the paper grain (machine direction) are compared with others developed at right angles to the grain; therefore, the orientation of paper grain with respect to solvent flow should be maintained constant in a series of chromatograms. (The machine direction is usually designated by the manufacturer on packages of chromatography paper.)

## Descending Chromatography

In descending chromatography, the mobile phase flows downward on the chromatographic sheet.

**Apparatus**— The essential equipment for descending chromatography consists of the following:

A vapor-tight chamber provided with inlets for addition of solvent or for releasing internal pressure. The chamber is constructed preferably of glass, stainless steel, or porcelain and is so designed as to permit observation of the progress of the chromatographic run without opening of the chamber. Tall glass cylinders are convenient if they are made vapor-tight with suitable covers and a sealing compound.

A rack of corrosion-resistant material about 5 cm shorter than the inside height of the chamber. The rack serves as a support for solvent troughs and for antisiphon rods which, in turn, hold up the chromatographic sheets.

One or more glass troughs capable of holding a volume of solvent greater than that needed for one chromatographic run. The troughs must also be longer than the width of the chromatographic sheets.

Heavy glass antisiphon rods to be supported by the rack and running outside of, parallel to, and slightly above the edge of the glass trough.

Chromatographic sheets of special filter paper at least 2.5 cm wide and not wider than the length of the troughs are cut to a length approximately equal to the height of the chamber. A fine pencil line is drawn horizontally across the filter paper at a distance from one end such that, when the sheet is suspended from the antisiphon rods with the upper end of the paper resting in the trough and the lower portion hanging free into the chamber, the line is located a few centimeters below the rods. Care is necessary to avoid contaminating the filter paper by excessive handling or by contact with dirty surfaces.

Procedure— The substance or substances to be analyzed are dissolved in a suitable solvent. Convenient volumes, delivered from suitable micropipets, of the resulting solution, normally containing 1 to 20 µg of the compound, are placed in 6- to 10-mm spots not less than 3 cm apart along the pencil line. If the total volume to be applied would produce spots of a diameter greater than 6 to 10 mm, it is applied in separate portions to the same spot, each portion being allowed to dry before the next is added.

The spotted chromatographic sheet is suspended in the chamber by use of the antisiphon rod, which holds the upper end of the sheet in the solvent trough. The bottom of the chamber is covered with the prescribed solvent system. Saturation of the chamber with solvent vapor is facilitated by lining the inside walls with paper that is wetted with the prescribed solvent system. It is important to ensure that the portion of the sheet hanging below the rods is freely suspended in the chamber without touching the rack or the chamber walls or the fluid in the chamber. The chamber is sealed to allow equilibration (saturation) of the chamber and the paper with the solvent vapor. Any excess pressure is released as necessary. For large chambers, equilibration overnight may be necessary.

A volume of the mobile phase in excess of the volume required for complete development of the chromatogram is saturated with the immobile phase by shaking. After equilibration of the chamber, the prepared mobile solvent is introduced into the trough through the inlet. The inlet is closed and the mobile solvent phase is allowed to travel the desired distance down the paper. Precautions must be taken against allowing the solvent to run down the sheet when opening the chamber and removing the chromatogram. The location of the solvent front is quickly marked, and the sheets are dried.

The chromatogram is observed and measured directly or after suitable development to reveal the location of the spots of the isolated drug or drugs. The paper section(s) predetermined to contain the isolated drug(s) may be cut out and eluted by an appropriate solvent, and the solutions may be made up to a known volume and quantitatively analyzed by appropriate chemical or instrumental techniques. Similar procedures should be conducted with various amounts of similarly spotted reference standard on the same paper in the concentration range appropriate to prepare a valid calibration curve.

#### Ascending Chromatography

In ascending chromatography, the lower edge of the sheet (or strip) is dipped into the mobile phase to permit the mobile phase to rise on the chromatographic sheet by capillary action.

Apparatus— The essential equipment for ascending chromatography is substantially the same as that described under Descending Chromatography.

Procedure— The test materials are applied to the chromatographic sheets as directed under Descending Chromatography, and above the level to which the paper is dipped into the developing solvent. The bottom of the developing chamber is covered with the developing solvent system. If a two-phase system is used, both phases are added. It is also desirable to line the walls of the chamber with paper and to saturate this lining with the solvent system. Empty solvent troughs are placed on the bottom of the chamber, and the chromatographic sheets are suspended so that the end on which the spots have been added hangs free inside the empty trough.

The chamber is sealed, and equilibration is allowed to proceed as described under Descending Chromatography. Then the developing solvent (mobile phase) is added through the inlet to the trough in excess of the solvent required for complete moistening of the chromatographic sheet. The chamber is resealed. When the solvent front has reached the desired height, the chamber is opened and the sheet is removed and dried.

Quantitative analyses of the spots may be conducted as described under Descending Chromatography.

#### THIN-LAYER CHROMATOGRAPHY

In thin-layer chromatography, the adsorbent is a relatively thin, uniform layer of dry, finely powdered material applied to a glass, plastic, or metal sheet or plate, glass plates being most commonly employed. The coated plate can be considered an "open chromatographic column" and the separations achieved may be based upon adsorption, partition, or a combination of both effects, depending on the particular type of stationary phase, its preparation, and its use with different solvents. Thin-layer chromatography on ion-exchange layers can be used for the fractionation of polar compounds. Presumptive identification can be effected by observation of spots or zones of identical RF value and about equal magnitude obtained, respectively, with an unknown and a reference sample chromatographed on the same plate. A visual comparison of the size or intensity of the spots or zones may serve for semiquantitative estimation. Quantitative measurements are possible by means of densitometry (absorbance or fluorescence measurements), or the spots may be carefully removed from the plate, followed by elution with a suitable solvent and spectrophotometric measurement. For two-dimensional thin-layer chromatography, the chromatographed plate is turned at a right angle and again chromatographed, usually in another chamber equilibrated with a different solvent system.

Apparatus— Acceptable apparatus and materials for thin-layer chromatography consist of the following.

A TLC or HPTLC plate. The chromatography is generally carried out using precoated plates or sheets (on glass, aluminum, or polyester support) of suitable size. It may be necessary to clean the plates prior to separation. This can be done by migration of, or immersion in, an appropriate solvent. The plates may also be impregnated by procedures such as development, immersion, or spraying. At the time of use, the plates may be activated, if necessary, by heating in an oven at 120° for 20 minutes. The stationary phase of TLC plates has an average particle size of 10–15 µm, and that of HPTLC plates an average particle size of 5 µm. Commercial plates with a preadsorbant zone can be used if they are specified in a monograph. Sample applied to the preabsorbant region develops into sharp, narrow bands at the preabsorbant-sorbent interface. Alternatively, flat glass plates of convenient size, typically 20 cm × 20 cm can be coated as described under Preparation of Chromatographic Plates.

A suitable manual, semiautomatic, or automatic application device can be used to ensure proper positioning of the plate and proper transfer of the sample, with respect to volume and position, onto the plate. Alternatively, a template can be used to guide in manually placing the test spots at definite intervals, to mark distances as needed, and to aid in labeling the plates. For the proper application of the solutions, micropipets, microsyringes, or calibrated disposable capillaries are recommended.

For ascending development, a chromatographic chamber made of inert, transparent material and having the following specifications is used: a flat bottom or twin trough, a tightly fitted lid, and a size suitable for the plates. For horizontal development, the chamber is provided with a reservoir for the mobile phase, and it also contains a device for directing the mobile phase to the stationary phase.

Devices for transfer of reagents onto the plate by spraying, immersion, or exposure to vapor and devices to facilitate any necessary heating for visualization of the separated spots or zones.

A UV light source suitable for observations under short (254 nm) and long (365 nm) wavelength UV light.

A suitable device for documentation of the visualized chromatographic result.

Procedure— Apply the prescribed volume of the test solution and the standard solution in sufficiently small portions to obtain circular spots of 2 to 5 mm in diameter (1 to 2 mm on HPTLC plates) or bands of 10 to 20 mm by 1 to 2 mm (5 to 10 mm by 0.5 to 1 mm on HPTLC plates) at an appropriate distance from the lower edge—during chromatography the application position must be at least 3 mm (HPTLC) or 5 mm (TLC) above the level of the developing solvent—and from the sides of the plate. Apply the solutions on a line parallel to the lower edge of the plate with an interval of at least 10 mm (5 mm on HPTLC plates) between the centers of spots or 4 mm (2 mm on HPTLC plates) between the edges of bands, and allow to dry.

Ascending Development— Line at least one wall of the chromatographic chamber with filter paper. Pour into the chromatographic chamber a quantity of the mobile phase sufficient for the size of the chamber to give, after impregnation of the filter paper, a level of depth appropriate to the dimension of the plate used. For saturation of the chromatographic chamber, close the lid, and allow the system to equilibrate. Unless otherwise indicated, the chromatographic separation is performed in a saturated chamber.

Place the plate in the chamber, ensuring that the plate is as vertical as possible and that the spots or bands are above the surface of the mobile phase, and close the chamber. The stationary phase faces the inside of the chamber. Remove the plate when the mobile phase has moved over the prescribed distance. Dry the plate, and visualize the chromatograms as prescribed. For two-dimensional chromatography, dry the plates after the first development, and carry out a second development in a direction perpendicular to that of the first development.

**Horizontal Development**— Introduce a sufficient quantity of the developing solvent into the reservoir of the chamber using a syringe or pipet. Place the plate horizontally in the chamber, connect the mobile phase direction device according to the manufacturer's instructions, and close the chamber. If prescribed, develop the plate starting simultaneously at both ends. Remove the plate when the mobile phase has moved over the distance prescribed in the monograph. Dry the plate, and visualize the chromatograms as prescribed.

For two-dimensional chromatography, dry the plates after the first development, and carry out a second development in a direction perpendicular to that of the first development.

**Detection**— Observe the dry plate first under short-wavelength UV light (254 nm) and then under long-wavelength UV light (365 nm) or as stated in the monograph. If further directed, spray, immerse, or expose the plate to vapors of the specified reagent, heat the plate when required, observe, and compare the test chromatogram with the standard chromatogram.

Document the plate after each observation. Measure and record the distance of each spot or zone from the point of origin, and indicate for each spot or zone the wavelength under which it was observed. Determine the RF values for the principal spots or zones (see *Glossary of Symbols*).

**Quantitative Measurement**— Using appropriate instrumentation, substances separated by TLC and responding to ultraviolet-visible (UV-Vis) irradiation prior to or after derivatization can be determined directly on the plate. While moving the plate or the measuring device, the plate is examined by measuring the reflectance of the incident light. Similarly, fluorescence may be measured using an appropriate optical system. Substances containing radionuclides can be quantified in three ways: (1) directly by moving the plate alongside a suitable counter or vice versa; (2) by cutting the plates into strips and measuring the radioactivity on each individual strip using a suitable counter; or (3) by scraping off the stationary phase, dissolving it in a suitable scintillation cocktail, and measuring the radioactivity using a liquid scintillation counter (see [Radioactivity \(821\)](#)).

The apparatus for direct quantitative measurement on the plate is a densitometer that is composed of a mechanical device to move the plate or the measuring device along the x-axis and the y-axis, a recorder, a suitable integrator or a computer; and, for substances responding to UV-Vis irradiation, a photometer with a source of light, an optical device capable of generating monochromatic light, and a photo cell of adequate sensitivity, all of which are used for the measurement of reflectance. In the case where fluorescence is measured, a suitable filter is also required to prevent the light used for excitation from reaching the photo cell while permitting the emitted light or specific portions thereof to pass. The linearity range of the counting device must be verified.

For quantitative tests, it is necessary to apply to the plate not fewer than three standard solutions of the substance to be examined, the concentrations of which span the expected value in the test solution (e.g., 80%, 100%, and 120%). Derivatize with the prescribed reagent, if necessary, and record the reflectance or fluorescence in the chromatograms obtained.

Use the measured results for the calculation of the amount of substance in the test solution.

#### Preparation of Chromatographic Plates— Apparatus—

Flat glass plates of convenient size, typically 20 cm × 20 cm.

An aligning tray or a flat surface upon which to align and rest the plates during the application of the adsorbent.

A storage rack to hold the prepared plates during drying and transportation. The rack holding the plates should be kept in a desiccator or be capable of being sealed in order to protect the plates from the environment after removal from the drying oven.

The adsorbent consists of finely divided adsorbent materials, normally 5 to 40 µm in diameter, suitable for chromatography. It can be applied directly to the glass plate or can be bonded to the plate by means of plaster of Paris [calcium sulfate hemihydrate (at a ratio of 5% to 15%)] or with starch paste or other binders. The plaster of Paris will not yield as hard a surface as will the starch, but it is not affected by strongly oxidizing spray reagents. The adsorbent may contain fluorescing material to aid in the visualization of spots that absorb UV light.

A spreader, which, when moved over the glass plate, will apply a uniform layer of adsorbent of desired thickness over the entire surface of the plate.

**Procedure**— [note—In this procedure, use Purified Water that is obtained by distillation.] Clean the glass plates scrupulously, using an appropriate cleaning solution (see [Cleaning Glass Apparatus \(1051\)](#)), rinsing them with copious quantities of water until the water runs off the plates without leaving any visible water or oily spots, then dry. It is important that the plates be completely free from lint and dust when the adsorbent is applied.

Arrange the plate or plates on the aligning tray, place a 5- × 20-cm plate adjacent to the front edge of the first square plate and another 5- × 20-cm plate adjacent to the rear edge of the last square, and secure all of the plates so that they will not slip during the application of the adsorbent. Position the spreader on the end plate opposite the raised end of the aligning tray. Mix 1 part of adsorbent with 2 parts of water (or in the ratio suggested by the supplier) by shaking vigorously for 30 seconds in a glass-stoppered conical flask, and transfer the slurry to the spreader. Usually 30 g of adsorbent and 60 mL of water are sufficient for five 20- × 20-cm plates. Complete the application of adsorbents using plaster of Paris binder within 2 minutes of the addition of the water, because thereafter the mixture begins to harden. Draw the spreader smoothly over the plates toward the raised end of the aligning tray, and remove the spreader when it is on the end plate next to the raised end of the aligning tray. (Wash away all traces of adsorbent from the spreader immediately after use.) Allow the plates to remain undisturbed for 5 minutes, then transfer the square plates, layer side up, to the storage rack, and dry at 105° for 30 minutes. Preferably place the rack at an angle in the drying oven to prevent the condensation of moisture on the back sides of plates in the rack. When the plates are dry, allow them to cool to room temperature, and inspect the uniformity of the distribution and the texture of the adsorbent layer; transmitted light will show uniformity of distribution, and reflected light will show uniformity of texture. Store the satisfactory plates over silica gel in a suitable chamber.

#### COLUMN CHROMATOGRAPHY

**Apparatus**— The apparatus required for column chromatographic procedures is simple, consisting only of the chromatographic tube itself and a tamping rod, which may be needed to pack a pledget of glass wool or cotton, if needed, in the base of the tube and compress the adsorbent or slurry uniformly within the tube. In some cases a porous glass disk is sealed at the base of the tube in order to support the contents. The tube is cylindrical and is made of glass, unless another material is specified in the individual monograph. A smaller-diameter delivery tube is fused or otherwise attached by a leakproof joint to the lower end of the main tube. Column dimensions are variable; the dimensions of those commonly used in pharmaceutical analysis range from 10 to 30 mm in uniform inside diameter and 150 to 400 mm in length, exclusive of the delivery tube. The delivery tube, usually 3 to 6 mm in inside diameter, may include a stopcock for accurate control of the flow rate of solvents through the column. The tamping rod, a cylindrical ram firmly attached to a shaft, may be constructed of plastic, glass, stainless steel, or aluminum, unless another material is specified in the individual monograph. The shaft of the rod is substantially smaller in diameter than the column and is not less than 5 cm longer than the effective length of the column. The ram has a diameter about 1 mm smaller than the inside diameter of the column.

#### Column Adsorption Chromatography

The adsorbent (such as activated alumina or silica gel, calcined diatomaceous silica, or chromatographic purified siliceous earth) as a dry solid or as a slurry is packed into a glass or quartz chromatographic tube. A solution of the drug in a small amount of solvent is added to the top of the column and allowed to flow into the adsorbent. The drug principles are quantitatively removed from the solution and are adsorbed in a narrow transverse band at the top of the column. As additional solvent is allowed to flow through the column, either by gravity or by application of air pressure, each substance progresses down the column at a characteristic rate resulting in a spatial separation to give what is known as the chromatogram. The rate of movement for a given substance is affected by several variables, including the adsorptive power of the adsorbent and its particle size and surface area; the nature and polarity of the solvent; the hydrostatic head or applied pressure; and the temperature of the chromatographic system.

If the separated compounds are colored or if they fluoresce under UV light, the adsorbent column may be extruded and, by transverse cuts, the appropriate segments may then be isolated. The desired compounds are then extracted from each segment with a suitable solvent. If the compounds are colorless, they may be located by means of painting or spraying the extruded column with color-forming reagents. Chromatographed radioactive substances may be located by means of Geiger-Müller detectors or similar sensing and recording instruments. Clear plastic tubing made of a material such as nylon, which is inert to most solvents and transparent to short-wavelength UV light, may be packed with adsorbent and used as a chromatographic column. Such a column may be sliced with a sharp knife without removing the packing from the tubing. If a fluorescent adsorbent is used, the column may

be marked under UV light in preparation for slicing.

A "flowing" chromatogram, which is extensively used, is obtained by a procedure in which solvents are allowed to flow through the column until the separated drug appears in the effluent solution, known as the "eluate." The drug may be determined in the eluate by titration or by a spectrophotometric or colorimetric method, or the solvent may be evaporated, leaving the drug in more or less pure form. If a second drug principle is involved, it is eluted by continuing the first solvent or by passing a solvent of stronger eluting power through the column. The efficiency of the separation may be checked by obtaining a thin-layer chromatogram on the individual fractions.

A modified procedure for adding the mixture to the column is sometimes employed. The drug, in a solid form, and, as in the case of a powdered tablet, without separation from the excipients, is mixed with some of the adsorbent and added to the top of a column. The subsequent flow of solvent moves the drug down the column in the manner described.

#### Column Partition Chromatography

In partition chromatography the substances to be separated are partitioned between two immiscible liquids, one of which, the immobile phase, is adsorbed on a Solid Support, thereby presenting a very large surface area to the flowing solvent or mobile phase. The exceedingly high number of successive liquid-liquid contacts allows an efficiency of separation not achieved in ordinary liquid-liquid extraction.

The Solid Support is usually polar, and the adsorbed immobile phase more polar than the mobile phase. The Solid Support that is most widely used is chromatographic siliceous earth having a particle size suitable to permit proper flow of eluant.<sup>1</sup> In reverse-phase partition chromatography the adsorbed immobile phase is less polar than the mobile phase and the solid adsorbent is rendered nonpolar by treatment with a silanizing agent, such as dichlorodimethylsilane, to give silanized chromatographic siliceous earth.

The sample to be chromatographed is usually introduced into the chromatographic system in one of two ways: (a) a solution of the sample in a small volume of the mobile phase is added to the top of the column; or, (b) a solution of the sample in a small volume of the immobile phase is mixed with the Solid Support and transferred to the column as a layer above a bed of a mixture of immobile phase with adsorbent.

Development and elution are accomplished with flowing solvent as before. The mobile solvent usually is saturated with the immobile solvent before use.

In conventional liquid-liquid partition chromatography, the degree of partition of a given compound between the two liquid phases is expressed by its partition or distribution coefficient. In the case of compounds that dissociate, distribution can be controlled by modifying the pH, dielectric constant, ionic strength, and other properties of the two phases. Selective elution of the components of a mixture can be achieved by successively changing the mobile phase to one that provides a more favorable partition coefficient, or by changing the pH of the immobile phase in situ with a mobile phase consisting of a solution of an appropriate acid or base in an organic solvent.

Unless otherwise specified in the individual monograph, assays and tests that employ column partition chromatography are performed according to the following general methods.

**Solid Support**— Use purified siliceous earth. Use silanized chromatographic siliceous earth for reverse-phase partition chromatography.

**Stationary Phase**— Use the solvent or solution specified in the individual monograph. If a mixture of liquids is to be used as the Stationary Phase, mix them prior to the introduction of the Solid Support.

**Mobile Phase**— Use the solvent or solution specified in the individual monograph. Equilibrate it with water if the Stationary Phase is an aqueous solution; if the Stationary Phase is a polar organic fluid, equilibrate with that fluid.

**Preparation of Chromatographic Column**— Unless otherwise specified in the individual monograph, the chromatographic tube is about 22 mm in inside diameter and 200 to 300 mm in length, without porous glass disk, to which is attached a delivery tube, without stopcock, about 4 mm in inside diameter and about 50 mm in length. Pack a puglet of fine glass wool in the base of the tube. Place the specified volume of Stationary Phase in a 100- to 250-mL beaker, add the specified amount of Solid Support, and mix to produce a homogeneous, fluffy mixture. Transfer this mixture to the chromatographic tube, and tamp, using gentle pressure, to obtain a uniform mass. If the specified amount of Solid Support is more than 3 g, transfer the mixture to the column in portions of approximately 2 g, and tamp each portion. If the assay or test requires a multisegment column, with a different Stationary Phase specified for each segment, tamp after the addition of each segment, and add each succeeding segment directly to the previous one.

If a solution of the analyte is incorporated in the Stationary Phase, complete the quantitative transfer to the chromatographic tube by scrubbing the beaker used for the preparation of the test mixture with a mixture of about 1 g of Solid Support and several drops of the solvent used to prepare the test solution.

Pack a puglet of fine glass wool above the completed column packing. The Mobile Phase flows through a properly packed column as a moderate stream or, if reverse-phase chromatography is applied, as a slow trickle.

**Procedure**— Transfer the Mobile Phase to the column space above the column packing, and allow it to flow through the column under the influence of gravity. Rinse the tip of the chromatographic column with about 1 mL of Mobile Phase before each change in composition of Mobile Phase and after completion of the elution. If the analyte is introduced into the column as a solution in the Mobile Phase, allow it to pass completely into the column packing, then add Mobile Phase in several small portions, allowing each to drain completely, before adding the bulk of the Mobile Phase. Where the assay or test requires the use of multiple chromatographic columns mounted in series and the addition of Mobile Phase in divided portions is specified, allow each portion to drain completely through each column, and rinse the tip of each with Mobile Phase prior to the addition of each succeeding portion.

#### GAS CHROMATOGRAPHY

The distinguishing features of gas chromatography are a gaseous mobile phase and a solid or immobilized liquid stationary phase. Liquid stationary phases are available in packed or capillary columns. In the packed columns, the liquid phase is deposited on a finely divided, inert solid support, such as diatomaceous earth, porous polymer, or graphitized carbon, which is packed into a column that is typically 2 to 4 mm in internal diameter and 1 to 3 m in length. In capillary columns, which contain no packing, the liquid phase is deposited on the inner surface of the column and may be chemically bonded to it. In gas-solid chromatography, the solid phase is an active adsorbent, such as alumina, silica, or carbon, packed into a column. Polyaromatic porous resins, which are sometimes used in packed columns, are not coated with a liquid phase.

When a vaporized compound is introduced into the carrier gas and carried into the column, it is partitioned between the gas and stationary phases by a dynamic countercurrent distribution process. The compound is carried down the column by the carrier gas, retarded to a greater or lesser extent by sorption and desorption on the stationary phase. The elution of the compound is characterized by the partition ratio,  $k'$ , a dimensionless quantity also called the capacity factor (see Glossary of Symbols for the definition of symbols). It is equivalent to the ratio of the time required for the compound to flow through the column (the retention time) to the elution time of an unretained compound. The value of the capacity factor depends on the chemical nature of the compound, the nature, amount, and surface area of the liquid phase, the column temperature, and the gas flow rate. Under a specified set of experimental conditions, a characteristic capacity factor exists for every compound. Separation by gas chromatography occurs only if the compounds concerned have different capacity factors.

**Apparatus**— A gas chromatograph consists of a carrier gas source, an injection port, column, detector, and recording device. The injection port, column, and detector are temperature-controlled. The typical carrier gas is helium, nitrogen, or hydrogen, depending on the column and detector in use. The gas is supplied from a high-pressure cylinder or high-purity gas generator and passes through suitable pressure-reducing valves and a flow meter to the injection port and column. Compounds to be chromatographed, either in solution or as gases, are injected into the gas stream at the injection port. Depending upon the configuration of the apparatus, the test mixture may be injected directly into the column or be vaporized in the injection port and mixed into the flowing carrier gas prior to entering the column.

Once in the column, compounds in the test mixture are separated by virtue of differences in their capacity factors, which in turn depend upon vapor pressure and degree of interaction with the stationary phase. The capacity factor, which governs resolution, retention times, and column efficiencies of components of the test mixture, is also temperature-dependent.

The use of temperature-programmable column ovens takes advantage of this dependence to achieve efficient separation of compounds differing widely in vapor pressure.

As resolved compounds emerge separately from the column, they pass through a differential detector, which responds to the amount of each compound present. The type of detector to be used depends upon the nature of the compounds to be analyzed and is specified in the individual monograph. Detectors are heated to prevent condensation of the eluting compounds.

Detector output is recorded as a function of time, producing a chromatogram, which consists of a series of peaks on a time axis. Each peak represents a compound in the vaporized test mixture, although some peaks may overlap. The elution time is a characteristic of an individual compound; and the instrument response, measured as peak area or peak height, is

a function of the amount present.

Injectors—Sample injection devices range from simple syringes to fully programmable automatic injectors. The amount of sample that can be injected into a capillary column without overloading is small compared to the amount that can be injected into packed columns, and may be less than the smallest amount that can be manipulated satisfactorily by syringe. Capillary columns, therefore, often are used with injectors able to split samples into two fractions, a small one that enters the column and a large one that goes to waste. Such injectors may be used in a splitless mode for analyses of trace or minor components.

Purge and trap injectors are equipped with a sparging device by which volatile compounds in solution are carried into a low-temperature trap. When sparging is complete, trapped compounds are desorbed into the carrier gas by rapid heating of the temperature-programmable trap.

Headspace injectors are equipped with a thermostatically controlled sample heating chamber. Solid or liquid samples in tightly closed containers are heated in the chamber for a fixed period of time, allowing the volatile components in the sample to reach an equilibrium between the nongaseous phase and the gaseous or headspace phase.

After this equilibrium has been established, the injector automatically introduces a fixed amount of the headspace in the sample container into the gas chromatograph.

Columns—Capillary columns, which are usually made of fused silica, are typically 0.2 to 0.53 mm in internal diameter and 5 to 60 m in length. The liquid or stationary phase, which is sometimes chemically bonded to the inner surface, is 0.1 to 1.0  $\mu$ m thick, although nonpolar stationary phases may be up to 5  $\mu$ m thick. A list of liquid phases in current use is given in the section Chromatographic Reagents.

Packed columns, made of glass or metal, are 1 to 3 m in length with internal diameters of 2 to 4 mm. Those used for analysis typically are porous polymers or solid supports with liquid phase loadings of about 5% (w/w). High-capacity columns, with liquid phase loadings of about 20% (w/w), are used for large test specimens and for the determination of low molecular weight compounds such as water. The capacity required influences the choice of solid support.

Supports for analysis of polar compounds on low-capacity, low-polarity liquid phase columns must be inert to avoid peak tailing. The reactivity of support materials can be reduced by silanizing prior to coating with liquid phase. Acid-washed, flux-calcined diatomaceous earth is often used for drug analysis. Support materials are available in various mesh sizes, with 80- to 100-mesh and 100- to 120-mesh being most commonly used with 2- to 4-mm columns. Supports and liquid phases are listed in the section Chromatographic Reagents.

Retention time and the peak efficiency depend on the carrier gas flow rate; retention time is also directly proportional to column length, while resolution is proportional to the square root of the column length. For packed columns, the carrier gas flow rate is usually expressed in mL per minute at atmospheric pressure and room temperature. It is measured at the detector outlet with a flowmeter while the column is at operating temperature. The linear flow rate through a packed column is inversely proportional to the square of the column diameter for a given flow volume. Flow rates of 60 mL per minute in a 4-mm column and 15 mL per minute in a 2-mm column give identical linear flow rates and thus similar retention times. Unless otherwise specified in the individual monograph, flow rates for packed columns are about 30 to 60 mL per minute. For capillary columns, linear flow velocity is often used instead of flow rate. This is conveniently determined from the length of the column and the retention time of a dilute methane sample, provided a flame-ionization detector is in use. At high operating temperatures there is sufficient vapor pressure to result in a gradual loss of liquid phase, a process called bleeding.

Detectors—Flame-ionization detectors are used for most pharmaceutical analyses, with lesser use made of thermal conductivity, electron-capture, nitrogen-phosphorus, and mass spectrometric detectors. For quantitative analyses, detectors must have a wide linear dynamic range: the response must be directly proportional to the amount of compound present in the detector over a wide range of concentrations. Flame-ionization detectors have a wide linear range and are sensitive to most organic compounds. Detector response depends on the structure and concentration of the compound and on the flow rates of the combustion, air, makeup, and carrier gases. Unless otherwise specified in individual monographs, flame-ionization detectors with either helium or nitrogen carrier gas are to be used for packed columns, and helium or hydrogen is used for capillary columns.

The thermal conductivity detector employs a heated wire placed in the carrier gas stream. When an analyte enters the detector with the carrier gas, the difference in thermal conductivity of the gas stream (carrier and sample components) relative to that of a reference flow of carrier gas alone is measured. In general, the thermal conductivity detector responds uniformly to volatile compounds regardless of structure; however, it is considerably less sensitive than the flame-ionization detector.

The alkali flame-ionization detector, sometimes called an NP or nitrogen-phosphorus detector, contains a thermionic source, such as an alkali-metal salt or a glass element containing rubidium or other metal, that results in the efficient ionization of organic nitrogen and phosphorus compounds. It is a selective detector that shows little response to hydrocarbons.

The electron-capture detector contains a radioactive source of ionizing radiation. It exhibits an extremely high response to compounds containing halogens and nitro groups but little response to hydrocarbons. The sensitivity increases with the number and atomic weight of the halogen atoms.

Data Collection Devices—Modern data stations receive the detector output, calculate peak areas and peak heights, and print chromatograms, complete with run parameters and peak data. Chromatographic data may be stored and reprocessed, with integration and other calculation variables being changed as required. Data stations are used also to program the chromatograph, controlling most operational variables and providing for long periods of unattended operation.

Data can also be collected for manual measurement on simple recorders or on integrators whose capabilities range from those providing a printout of peak areas to those providing chromatograms with peak areas and peak heights calculated and data stored for possible reprocessing.

Procedure—Packed and capillary columns must be conditioned before use until the baseline and other characteristics are stable. This may be done by operation at a temperature above that called for by the method or by repeated injections of the compound or mixture to be chromatographed. The column or packing material supplier provides instructions for the recommended conditioning procedure. In the case of thermally stable methyl- and phenyl-substituted polysiloxanes, a special sequence increases inertness and efficiency; maintain the column at a temperature of 250° for 1 hour, with helium flowing, to remove oxygen and solvents. Stop the flow of helium, heat at about 340° for 4 hours, then reduce the heating to a temperature of 250°, and condition with helium flowing until stable.

Most drugs are reactive polar molecules. Successful chromatography may require conversion of the drug to a less polar and more volatile derivative by treatment of reactive groups with appropriate reagents. Silylating agents are widely used for this purpose and are readily available.

Assays require quantitative comparison of one chromatogram with another. A major source of error is irreproducibility in the amount of sample injected, notably when manual injections are made with a syringe. The effects of variability can be minimized by addition of an internal standard, a noninterfering compound present at the same concentration in test and standard solutions. The ratio of peak response of the analyte to that of the internal standard is compared from one chromatogram to another. Where the internal standard is chemically similar to the substance being determined, there is also compensation for minor variations in column and detector characteristics. In some cases, the internal standard may be carried through the sample preparation procedure prior to gas chromatography to control other quantitative aspects of the assay. Automatic injectors greatly improve the reproducibility of sample injections and reduce the need for internal standards.

Many monographs require that system suitability requirements be met before samples are analyzed (see System Suitability and Interpretation of Chromatograms).

#### HIGH-PRESSURE LIQUID CHROMATOGRAPHY

High-pressure liquid chromatography (HPLC), sometimes called high-performance liquid chromatography, is a separation technique based on a solid stationary phase and a liquid mobile phase. Separations are achieved by partition, adsorption, or ion-exchange processes, depending upon the type of stationary phase used. HPLC has distinct advantages over gas chromatography for the analysis of organic compounds. Compounds to be analyzed are dissolved in a suitable solvent, and most separations take place at room temperature.

Thus, most drugs, being nonvolatile or thermally unstable compounds, can be chromatographed without decomposition or the necessity of making volatile derivatives. Most pharmaceutical analyses are based on partition chromatography and are completed within 30 minutes.

As in gas chromatography, the elution time of a compound can be described by the capacity factor,  $k'$  (see Glossary of Symbols), which depends on the chemical nature of the analyte, the composition and flow rate of the mobile phase, and the composition and surface area of the stationary phase. Column length is an important determinant of resolution. Only compounds having different capacity factors can be separated by HPLC.

Apparatus—A liquid chromatograph consists of a reservoir containing the mobile phase, a pump to force the mobile phase through the system at high pressure, an injector to introduce the sample into the mobile phase, a chromatographic column, a detector, and a data collection device such as a computer, integrator, or recorder. Short, small-bore columns containing densely packed particles of stationary phase provide for the rapid exchange of compounds between the mobile and stationary phases. In addition to receiving and reporting

detector output, computers are used to control chromatographic settings and operations, thus providing for long periods of unattended operation.

**Pumping Systems**—HPLC pumping systems deliver metered amounts of mobile phase from the solvent reservoirs to the column through high-pressure tubing and fittings. Modern systems consist of one or more computer-controlled metering pumps that can be programmed to vary the ratio of mobile phase components, as is required for gradient chromatography, or to mix isocratic mobile phases (i.e., mobile phases having a fixed ratio of solvents). However, the proportion of ingredients in premixed isocratic mobile phases can be more accurately controlled than in those delivered by most pumping systems. Operating pressures up to 5000 psi or higher, with delivery rates up to about 10 mL per minute are typical. Pumps used for quantitative analysis should be constructed of materials inert to corrosive mobile phase components and be capable of delivering the mobile phase at a constant rate with minimal fluctuations over extended periods of time.

**Injectors**—After dissolution in mobile phase or other suitable solution, compounds to be chromatographed are injected into the mobile phase, either manually by syringe or loop injectors, or automatically by autosamplers. The latter consist of a carousel or rack to hold sample vials with tops that have a pierceable septum or stopper and an injection device to transfer sample from the vials to a loop from which it is loaded into the chromatograph. Some autosamplers can be programmed to control sample volume, the number of injections and loop rinse cycles, the interval between injections, and other operating variables.

A syringe can be used for manual injection of samples through a septum when column head pressures are less than 70 atmospheres (about 1000 psi). At higher pressures an injection valve is essential. Some valve systems incorporate a calibrated loop that is filled with test solution for transfer to the column in the mobile phase. In other systems, the test solution is transferred to a cavity by syringe and then switched into the mobile phase.

**Columns**—For most pharmaceutical analyses, separation is achieved by partition of compounds in the test solution between the mobile and stationary phases. Systems consisting of polar stationary phases and nonpolar mobile phases are described as normal phase, while the opposite arrangement, polar mobile phases and nonpolar stationary phases, is called reverse-phase chromatography. Partition chromatography is almost always used for hydrocarbon-soluble compounds of molecular weight less than 1000. The affinity of a compound for the stationary phase, and thus its retention time on the column, is controlled by making the mobile phase more or less polar. Mobile phase polarity can be varied by the addition of a second, and sometimes a third or even a fourth, component.

Stationary phases for modern, reverse-phase liquid chromatography typically consist of an organic phase chemically bound to silica or other materials. Particles are usually 3 to 10  $\mu$ m in diameter, but sizes may range up to 50  $\mu$ m or more for preparative columns. Small particles thinly coated with organic phase provide for low mass transfer resistance and, hence, rapid transfer of compounds between the stationary and mobile phases. Column polarity depends on the polarity of the bound functional groups, which range from relatively nonpolar octadecyl silane to very polar nitrile groups. Liquid, nonbound stationary phases must be largely immiscible in the mobile phase. Even so, it is usually necessary to presaturate the mobile phase with stationary phase to prevent stripping of the stationary phase from the column. Polymeric stationary phases coated on the support are more durable.

Columns used for analytical separations usually have internal diameters of 2 to 5 mm; larger diameter columns are used for preparative chromatography. Columns may be heated to give more efficient separations, but only rarely are they used at temperatures above 60° because of potential stationary phase degradation or mobile phase volatility. Unless otherwise specified in the individual monograph, columns are used at ambient temperature.

**Ion-exchange chromatography** is used to separate water-soluble, ionizable compounds of molecular weight less than 1500. The stationary phases are usually synthetic organic resins; cation-exchange resins contain negatively charged active sites and are used to separate basic substances such as amines, while anion-exchange resins have positively charged active sites for separation of compounds with negatively charged groups, such as phosphate, sulfonate, or carboxylate groups. Water-soluble ionic or ionizable compounds are attracted to the resins, and differences in affinity bring about the chromatographic separation. The pH of the mobile phase, temperature, ion type, ionic concentration, and organic modifiers affect the equilibrium, and these variables can be adjusted to obtain the desired degree of separation.

In size-exclusion chromatography, columns are packed with a porous stationary phase. Molecules of the compounds being chromatographed are filtered according to size. Those too large to enter the pores pass unretained through the column. Smaller molecules enter the pores and are increasingly retained as molecular size decreases. These columns are typically used to measure aggregation and degradation of large molecules (see Size-Exclusion Chromatography section).

**Detectors**—Many compendial HPLC methods require the use of spectrophotometric detectors. Such a detector consists of a flow-through cell mounted at the end of the column. A beam of UV radiation passes through the flow cell and into the detector. As compounds elute from the column, they pass through the cell and absorb the radiation, resulting in measurable energy level changes.

Fixed, variable, and multi-wavelength detectors are widely available. Fixed wavelength detectors operate at a single wavelength, typically 254 nm, emitted by a low-pressure mercury lamp. Variable wavelength detectors contain a continuous source, such as a deuterium or high-pressure xenon lamp, and a monochromator or an interference filter to generate monochromatic radiation at a wavelength selected by the operator. The wavelength accuracy of a variable-wavelength detector equipped with a monochromator should be checked by the procedure recommended by its manufacturer; if the observed wavelengths differ by more than 3 nm from the correct values, recalibration of the instrument is indicated. Modern variable wavelength detectors can be programmed to change wavelength while an analysis is in progress. Multi-wavelength detectors measure absorbance at two or more wavelengths simultaneously. In diode array multi-wavelength detectors, continuous radiation is passed through the sample cell, then resolved into its constituent wavelengths, which are individually detected by the photodiode array. These detectors acquire absorbance data over the entire UV-visible range, thus providing the analyst with chromatograms at multiple, selectable wavelengths and spectra of the eluting peaks. Diode array detectors usually have lower signal-to-noise ratios than fixed or variable wavelength detectors, and thus are less suitable for analysis of compounds present at low concentrations.

Differential refractometer detectors measure the difference between the refractive index of the mobile phase alone and that of the mobile phase containing chromatographed compounds as it emerges from the column. Refractive index detectors are used to detect non-UV absorbing compounds, but they are less sensitive than UV detectors. They are sensitive to small changes in solvent composition, flow rate, and temperature, so that a reference column may be required to obtain a satisfactory baseline.

Fluorometric detectors are sensitive to compounds that are inherently fluorescent or that can be converted to fluorescent derivatives either by chemical transformation of the compound or by coupling with fluorescent reagents at specific functional groups. If derivatization is required, it can be done prior to chromatographic separation or, alternatively, the reagent can be introduced into the mobile phase just prior to its entering the detector.

Potentiometric, voltametric, or polarographic electrochemical detectors are useful for the quantitation of species that can be oxidized or reduced at a working electrode. These detectors are selective, sensitive, and reliable, but require conducting mobile phases free of dissolved oxygen and reducible metal ions. A pulseless pump must be used, and care must be taken to ensure that the pH, ionic strength, and temperature of the mobile phase remain constant. Working electrodes are prone to contamination by reaction products with consequent variable responses.

Electrochemical detectors with carbon-paste electrodes may be used advantageously to measure nanogram quantities of easily oxidized compounds, notably phenols and catechols. New detectors continue to be developed in attempts to overcome the deficiencies of those being used.

**Data Collection Devices**—Modern data stations receive and store detector output and print out chromatograms complete with peak heights, peak areas, sample identification, and method variables. They are also used to program the liquid chromatograph, controlling most variables and providing for long periods of unattended operation.

Data also may be collected on simple recorders for manual measurement or on stand-alone integrators, which range in complexity from those providing a printout of peak areas to those providing chromatograms with peak areas and peak heights calculated and data stored for possible subsequent reprocessing.

**Procedure**—The mobile phase composition significantly influences chromatographic performance and the resolution of compounds in the mixture being chromatographed. For accurate quantitative work, high-purity reagents and "HPLC grade" organic solvents must be used. Water of suitable quality should have low conductivity and low UV absorption, appropriate to the intended use.

Reagents used with special types of detectors (e.g., electrochemical, mass spectrometer) may require the establishment of additional tolerances for potential interfering species. Composition has a much greater effect than temperature on the capacity factor,  $k'$ .

In partition chromatography, the partition coefficient, and hence the separation, can be changed by addition of another component to the mobile phase. In ion-exchange chromatography, pH and ionic strength, as well as changes in the composition of the mobile phase, affect capacity factors. The technique of continuously changing the solvent composition during the chromatographic run is called gradient elution or solvent programming. It is sometimes used to chromatograph complex mixtures of components differing greatly

in their capacity factors. Detectors that are sensitive to change in solvent composition, such as the differential refractometer, are more difficult to use with the gradient elution technique.

The detector must have a broad linear dynamic range, and compounds to be measured must be resolved from any interfering substances. The linear dynamic range of a compound is the range over which the detector signal response is directly proportional to the amount of the compound. For maximum flexibility in quantitative work, this range should be about three orders of magnitude. HPLC systems are calibrated by plotting peak responses in comparison with known concentrations of a reference standard, using either an external or an internal standardization procedure.

Reliable quantitative results are obtained by external calibration if automatic injectors or autosamplers are used. This method involves direct comparison of the peak responses obtained by separately chromatographing the test and reference standard solutions. If syringe injection, which is irreproducible at the high pressures involved, must be used, better quantitative results are obtained by the internal calibration procedure where a known amount of a noninterfering compound, the internal standard, is added to the test and reference standard solutions, and the ratios of peak responses of drug and internal standard are compared.

Because of normal variations in equipment, supplies, and techniques, a system suitability test is required to ensure that a given operating system may be generally applicable. The main features of system suitability tests are described below.

For information on the interpretation of results, see the section Interpretation of Chromatograms.

#### Size-Exclusion Chromatography

Size-exclusion chromatography is a high-pressure liquid chromatographic technique that separates molecules in solution according to their size. Methods for size-exclusion chromatography are divided into gel permeation chromatographic methods, which utilize nonpolar organic mobile phases and hydrophilic packings, and gel filtration chromatographic methods, which utilize aqueous mobile phases and hydrophobic packings. The sample is introduced into a column, which is filled with a gel or a porous particle packing material and is carried by the mobile phase through the column. The size separation takes place by repeated exchange of the solute molecules between the solvent of the mobile phase and the same solvent in the stationary liquid phase within the pores of the packing material. The pore-size range of the packing material determines the molecular-size range within which separation can occur.

Molecules small enough to penetrate all the pore spaces elute at the total permeation volume,  $VT$ . On the other hand, molecules apparently larger than the maximum pore size of the packing material migrate along the column only through the spaces between the particles of the packing material without being retained and elute at the exclusion volume,  $VO$  (void volume). Separation according to molecular size occurs between the exclusion volume and the total permeation volume, useful separation usually occurring in the first two-thirds of this range.

Apparatus— The components of the chromatograph are described under High-Pressure Liquid Chromatography.

Column—If necessary, the column is temperature-controlled. It is packed with a separation material that is capable of fractionation in the appropriate range of molecular sizes and through which the eluent is passed at a constant rate. One end of the column is usually fitted with a suitable device for applying the sample, such as a flow adaptor, a syringe through a septum or an injection valve, and it may also be connected to a suitable pump for controlling the flow of the eluent. Alternatively, the sample may be applied directly to the drained bed surface, or, where the sample is denser than the eluent, it may be layered beneath the eluent. The packing material may be a soft support such as a swollen gel or a rigid support composed of a material such as glass, silica, or a solvent-compatible, cross-linked organic polymer. Rigid supports usually require pressurized systems giving faster separations. The mobile phase is chosen according to sample type, separation medium, and method of detection.

Detector—The outlet of the column is usually connected to a suitable detector fitted with an automatic recorder that enables the monitoring of the relative concentrations of separated components of the sample. Detectors are usually based on photometric, refractometric, or luminescent properties (see Detectors under High-Pressure Liquid Chromatography). An automatic fraction collector may be attached, if necessary.

Procedure— Before carrying out the separation, the packing material is treated and the column is packed, as described in the individual monograph or according to the manufacturer's instructions. Where necessary, procedures for verifying the suitability of the system are described in the individual monograph. The column efficiency may be evaluated from the number of theoretical plates,  $N$  (see the section Interpretation of Chromatograms). The elution characteristics of a compound in a particular column may be described by the distribution coefficient,  $KD$ , which is calculated by the formula:

$$(VI - VO) / (VT - VO)$$

in which  $VO$ ,  $VT$ , and  $VI$  are the retention volumes for the nonretained component, the component that has full access to all the pores in the support, and the compound under test, respectively. Each retention volume is measured from the time of application to the time of the peak maximum.

Determination of Relative Component Composition of Mixture—Carry out the separation as directed in the individual monograph. Monitor the elution of the components continuously, and measure the corresponding peak areas. If all the components under test exhibit equivalent responses to the physicochemical property being monitored (for example, if they exhibit corresponding absorptivities), calculate the relative amount of each component by dividing the respective peak area by the sum of the peak areas of all the components under test. If the responses to the property used for detection of the components under test are not equivalent, calculate the content using calibration curves obtained from the calibration procedure specified in the individual monograph.

Determination of Molecular Weights—Size-exclusion chromatography is used to determine molecular weights of components under test by comparison to calibration standards specified in the individual monograph. Plot the retention volumes of the calibration standards versus the logarithm of their molecular weights. Draw the line that best fits the plotted points within the exclusion and total permeation limits for the particular separation medium. From the calibration curve, molecular weights of components under test are estimated. This calibration is valid only for the particular macromolecular solute-solvent system used under the specified experimental conditions.

Determination of Molecular Weight Distribution of Polymers—The material used for calibration and the methods for determination of the distribution of molecular weights of polymers are specified in the individual monograph. However, sample comparison is valid only for results obtained under identical experimental conditions.

#### INTERPRETATION OF CHROMATOGRAMS

[Figure 1](#) represents a typical chromatographic separation of two substances, 1 and 2, where  $t_1$  and  $t_2$  are the respective retention times; and  $h$ ,  $h/2$ , and  $Wh/2$  are the height, the half-height, and the width at half-height, respectively, for peak 1.  $W_1$  and  $W_2$  are the respective widths of peaks 1 and 2 at the baseline. Air peaks are a feature of gas chromatograms and correspond to the solvent front in liquid chromatography. The retention time of these unretained components is designated as  $tM$ .

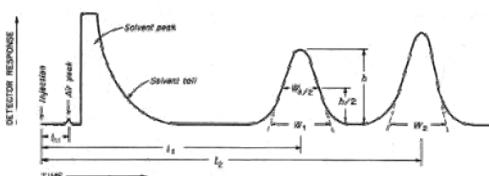

Figure 1. Chromatographic separation of two substances

Chromatographic retention times are characteristic of the compounds they represent but are not unique. Coincidence of retention times of a test and a reference substance can be used as a feature in construction of an identity profile but is insufficient on its own to establish identity. Absolute retention times of a given compound vary from one chromatogram to the next.

Because in most procedures there is no need to identify an unretained peak, comparisons are normally made in terms of relative retention times,  $Rr$ :

$$R_r = \frac{t_2}{t_1}$$

where  $t_2$  and  $t_1$  are the retention times, measured from the point of injection, of the test and the reference substances, respectively, determined under identical experimental conditions on the same column.

Other procedures may identify the peak position using the relative retention,  $r$ :

$$r = \frac{t_2 - t_M}{t_1 - t_M}$$

where  $t_M$  is the retention time of a non-retained marker, which needs to be defined in the procedure.

The number of theoretical plates,  $N$ , is a measure of column efficiency. For Gaussian peaks, it is calculated by the equation:

$$N = 16 \left( \frac{t}{W} \right)^2$$

where  $t$  is the retention time of the substance and  $W$  is the width of the peak at its base, obtained by extrapolating the relatively straight sides of the peak to the baseline. The value of  $N$  depends upon the substance being chromatographed as well as the operating conditions such as mobile phase or carrier gas flow rates and temperature, the quality of the packing, the uniformity of the packing within the column and, for capillary columns, the thickness of the stationary phase film, and the internal diameter and length of the column.

The separation of two components in a mixture, the resolution,  $R$ , is determined by the equation:

$$R = \frac{2(t_2 - t_1)}{W_2 + W_1}$$

in which  $t_2$  and  $t_1$  are the retention times of the two components, and  $W_2$  and  $W_1$  are the corresponding widths at the bases of the peaks obtained by extrapolating the relatively straight sides of the peaks to the baseline.

Where electronic integrators are used, it may be convenient to determine the resolution,  $R$ , by the equation:

$$R = \frac{2(t_2 - t_1)}{1.70(W_{1,h/2} + W_{2,h/2})}$$

and to determine the number of theoretical plates,  $N$ , by the equation:

$$N = 5.54(t/W_{h/2})^2$$

where  $W_{h/2}$  is the peak width at half-height, obtained directly by electronic integrators. However, in the event of dispute, only equations based on peak width at baseline are to be used.

Peak areas and peak heights are usually proportional to the quantity of compound eluting. These are commonly measured by electronic integrators but may be determined by more classical approaches. Peak areas are generally used but may be less accurate if peak interference occurs. For manual measurements, the chart should be run faster than usual, or a comparator should be used to measure the width at half-height and the width at the base of the peak, to minimize error in these measurements. For accurate quantitative work, the components to be measured should be separated from any interfering components. Peak tailing and fronting and the measurement of peaks on solvent tails are to be avoided.

Chromatographic purity tests for drug raw materials are sometimes based on the determination of peaks due to impurities, expressed as a percentage of the area due to the drug peak. It is preferable, however, to compare impurity peaks with those in the chromatogram of a standard at a similar concentration. The standard may be the drug itself at a level corresponding to, for example, 0.5% impurity, or in the case of toxic or signal impurities, a standard of the impurity itself.

#### SYSTEM SUITABILITY

System suitability tests are an integral part of gas and liquid chromatographic methods. They are used to verify that the resolution and reproducibility of the chromatographic system are adequate for the analysis to be done. The tests are based on the concept that the equipment, electronics, analytical operations, and samples to be analyzed constitute an integral system that can be evaluated as such.

The resolution,  $R$ , [note—All terms and symbols are defined in the Glossary of Symbols] is a function of column efficiency,  $N$ , and is specified to ensure that closely eluting compounds are resolved from each other, to establish the general resolving power of the system, and to ensure that internal standards are resolved from the drug. Column efficiency may be specified also as a system suitability requirement, especially if there is only one peak of interest in the chromatogram; however, it is a less reliable means to ensure resolution than direct measurement. Column efficiency is a measure of peak sharpness, which is important for the detection of trace components.

Replicate injections of a standard preparation used in the assay or other standard solution are compared to ascertain whether requirements for precision are met. Unless otherwise specified in the individual monograph, data from five replicate injections of the analyte are used to calculate the relative standard deviation,  $SR$ , if the requirement is 2.0% or less; data from six replicate injections are used if the relative standard deviation requirement is more than 2.0%.

The tailing factor,  $T$ , a measure of peak symmetry, is unity for perfectly symmetrical peaks and its value increases as tailing becomes more pronounced (see [Figure 2](#)). In some cases,

values less than unity may be observed. As peak asymmetry increases, integration, and hence precision, becomes less reliable.

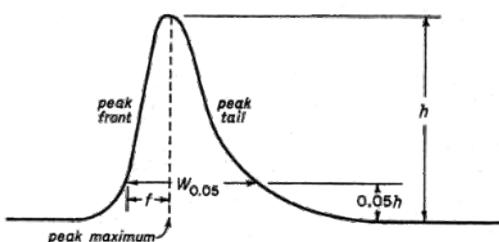

Figure 2. Asymmetrical chromatographic peak

These tests are performed by collecting data from replicate injections of standard or other solutions as specified in the individual monograph. The specification of definitive parameters in a monograph does not preclude the use of other suitable operating conditions (see Procedures under Tests and Assays in the General Notices). If adjustments of operating conditions to meet system suitability requirements are necessary, each of the following is the maximum variation that can be considered, unless otherwise directed in the monograph. Adjustments are permitted only when suitable standards (including Reference Standards) are available for all compounds used in the suitability test and only when those standards are used to show that the adjustments have improved the quality of the chromatography in meeting system suitability requirements. Adjustments to chromatographic systems performed in order to comply with system suitability requirements are not to be made to compensate for column failure or system malfunction. The changes described below may require additional validation data. The user should verify the suitability of the method under the new conditions by assessing the relevant analytical performance characteristics potentially affected by the change. Multiple adjustments can have a cumulative effect in the performance of the system and should be considered carefully before implementation.

pH of Mobile Phase (HPLC)—The pH of the aqueous buffer used in the preparation of the mobile phase can be adjusted to within  $\pm 0.2$  units of the value or range specified.

Concentration of Salts in Buffer (HPLC)—The concentration of the salts used in the preparation of the aqueous buffer used in the mobile phase can be adjusted to within  $\pm 10\%$ , provided the permitted pH variation (see above) is met.

Ratio of Components in Mobile Phase (HPLC)—The following adjustment limits apply to minor components of the mobile phase (specified at 50% or less). The amount(s) of these component(s) can be adjusted by  $\pm 30\%$  relative. However, the change in any component cannot exceed  $\pm 10\%$  absolute (i.e., in relation to the total mobile phase). Adjustment can be made to one minor component in a ternary mixture. Examples of adjustments for binary and ternary mixtures are given below.

#### Binary Mixtures—

specified ratio of 50:50—Thirty percent of 50 is 15% absolute, but this exceeds the maximum permitted change of  $\pm 10\%$  absolute in either component. Therefore, the mobile phase ratio may be adjusted only within the range of 40:60 to 60:40.

specified ratio of 2:98—Thirty percent of 2 is 0.6% absolute. Therefore the maximum allowed adjustment is within the range of 1.4:98.6 to 2.6:97.4.

#### Ternary Mixtures—

specified ratio of 60:35:5—For the second component, 30% of 35 is 10.5% absolute, which exceeds the maximum permitted change of  $\pm 10\%$  absolute in any component. Therefore the second component may be adjusted only within the range of 25% to 45% absolute. For the third component, 30% of 5 is 1.5% absolute. In all cases, a sufficient quantity of the first component is used to give a total of 100%. Therefore, mixture ranges of 50:45:5 to 70:25:5 or 58.5:35:6.5 to 61.5:35:3.5 would meet the requirement.

Wavelength of UV-Visible Detector (HPLC)—Deviations from the wavelengths specified in the method are not permitted. The procedure specified by the detector manufacturer, or another validated procedure, is to be used to verify that error in the detector wavelength is, at most,  $\pm 3$  nm.

Column Length (GC, HPLC): can be adjusted by as much as  $\pm 70\%$ .

Column Inner Diameter (GC, HPLC): can be adjusted by as much as  $\pm 25\%$  for HPLC and  $\pm 50\%$  for GC.

Film Thickness (Capillary GC): can be adjusted by as much as  $-50\%$  to  $100\%$ .

Particle Size (HPLC): can be reduced by as much as 50%.

Particle Size (GC): going from a larger to a smaller or a smaller to a larger (if it is the same "Range Ratio", which is the diameter of the largest particle divided by the diameter of the smallest particle) particle size GC mesh support is acceptable, provided the chromatography meets the requirements of the system suitability.

Flow Rate (GC, HPLC): can be adjusted by as much as  $\pm 50\%$ .

Injection Volume (GC, HPLC): can be reduced as far as is consistent with accepted precision and detection limits.

Column Temperature (HPLC): can be adjusted by as much as  $\pm 10^\circ$ . Column thermostating is recommended to improve control and reproducibility of retention time.

Oven Temperature (GC): can be adjusted by as much as  $\pm 10\%$ .

Oven Temperature Program (GC)—Adjustment of temperatures is permitted as stated above. For the times specified for the temperature to be maintained or for the temperature to be changed from one value to another, an adjustment of up to  $\pm 20\%$  is permitted.

Unless otherwise directed in the monograph, system suitability parameters are determined from the analyte peak.

Relative retention times may be provided in monographs for informational purposes only, to aid in peak identification. There are no acceptance criteria applied to relative retention times.

To ascertain the effectiveness of the final operating system, it should be subjected to suitability testing. Replicate injections of the standard preparation required to demonstrate adequate system precision may be made before the injection of samples or may be interspersed among sample injections. System suitability must be demonstrated throughout the run by injection of an appropriate control preparation at appropriate intervals, including at the end of the analysis. The control preparation can be a standard preparation or a solution containing a known amount of analyte and any additional materials useful in the control of the analytical system, such as excipients or impurities. Whenever there is a significant change in equipment or in a critical reagent, suitability testing should be performed before the injection of samples. No sample analysis is acceptable unless the requirements of system suitability have been met. Sample analyses obtained while the system fails system suitability requirements are unacceptable.

#### GLOSSARY OF SYMBOLS

To promote uniformity of interpretation, the following symbols and definitions are employed where applicable in presenting formulas in the individual monographs. Where a different symbol or definition is used in an individual monograph, the monograph text takes precedence (see General Notices). [note—Where the terms W and t both appear in the same equation they must be expressed in the same units.]

f distance from the peak maximum to the leading edge of the peak, the distance being measured at a point 5% of the peak height from the baseline.  
k' capacity factor.▲2▲USP32

$$k' = \frac{\text{amount of substance in stationary phase}}{\text{amount of substance in mobile phase}}$$

N

number of theoretical plates in a chromatographic column.<sup>▲2▲USP32</sup>

$$k' = \frac{\text{time spent by substance in stationary phase}}{\text{time spent by substance in mobile phase}} = \frac{t}{t_0} - 1$$

$$N = 16 \left( \frac{t}{W} \right)^2 \text{ or } N = 5.54 \left( \frac{t}{W_{1/2}} \right)^2$$

r

relative retention.<sup>▲2▲USP32</sup>

$$r = \frac{t_2 - t_M}{t_1 - t_M}$$

ri

peak response of an impurity obtained from a chromatogram.

rIS

peak response of the internal standard obtained from a chromatogram.

rS

peak response of the Reference Standard obtained from a chromatogram.

rU

peak response of the analyte obtained from a chromatogram.

R

resolution between two chromatographic peaks,

$$R = \frac{2(t_2 - t_1)}{W_1 + W_2}$$

$$\text{or } R = \frac{2(t_2 - t_1)}{1.70(W_{1,b/2} + W_{2,b/2})}$$

RF

chromatographic retardation factor equal to the ratio of the distance from the origin to the center of a zone divided by the distance from the origin to the solvent front.

Rr

relative retention time.<sup>▲2▲USP32</sup>

$$R_r = \frac{t_2}{t_1}$$

Rrel

relative retardation

$$R_{rel} = \frac{\text{distance traveled by test substance}}{\text{distance traveled by standard}}$$

RS

peak response ratio for a Standard preparation containing Reference Standard and internal standard,

$$R_S = \frac{r_s}{r_{IS}}$$

RU

peak response ratio for Assay preparation containing the analyte and internal standard,

$$R_U = \frac{r_U}{r_{IS}}$$

▲%RSD▲USP32

percent relative standard deviation,

$$\text{▲ } \%RSD = \frac{100}{\bar{X}} \left[ \sqrt{\frac{\sum_{i=1}^N (X_i - \bar{X})^2}{N-1}} \right] \text{ ▲USP32}$$

where  $X_i$  is an individual measurement in a set of  $N$  measurements and  $\bar{X}$  is the arithmetic mean of the set.

T

tailing factor.<sup>▲3▲USP32</sup>

$$T = \frac{W_{0.05}}{2f}$$

t

retention time measured from time of injection to time of elution of peak maximum.

tM

retention time of nonretarded component, air with thermal conductivity detection.

W

width of peak measured by extrapolating the relatively straight sides to the baseline.

Wh/2

width of peak at half height.

W0.05

width of peak at 5% height.

<sup>▲2</sup> The parameters  $k'$ ,  $N$ ,  $r$ , and  $Rr$  were developed for isothermal GC separations and isocratic HPLC separations. Because these terms are thermodynamic parameters, they are valid only for separations made at constant temperature, mobile phase composition, and flow rate. However, for separations made with a temperature program or solvent gradient, these parameters may be used simply as comparative means to ensure that adequate chromatographic conditions exist to perform the methods as intended in the monographs.

<sup>▲USP32</sup>

<sup>▲3</sup> It is also a common practice to measure the Asymmetry factor as the ratio of the distance between the vertical line connecting the peak apex with the interpolated baseline and the peak front, and the distance between that line and the peak back measured at 10% of the peak height (in Figure 2), it would be  $(W_{0.10} - f_{0.10}) / f_{0.10}$ . However, for the purposes of USP, only the formula presented in the Glossary of Symbols is valid.

<sup>▲USP32</sup>

#### CHROMATOGRAPHIC REAGENTS

A complete list of Packings (L), Phases (G), and Supports (S) used in USP–NF tests and assays is located under Chromatographic Reagents in the Reagents, Indicators, and Solutions section. This list is intended to be a convenient reference for the chromatographer to identify the pertinent chromatographic reagent specified in the individual monograph.

[note—Particle sizes given in the listing are those generally provided. Where other, usually finer, sizes are required, the individual monograph specifies the desired particle size. Within any category of packings or phases listed there may be a wide range of columns available. Where it is necessary to define more specifically the chromatographic conditions, the individual monograph so indicates.]

1 A suitable grade is acid-washed Celite 545, available from Johns-Manville Corp., 22 East 40th St., New York, NY 10016.

## 631 COLOR AND ACHROMICITY

**Definition**— For the purposes of this chapter, color may be defined as the perception or subjective response by an observer to the objective stimulus of radiant energy in the visible spectrum extending over the range 400 nm to 700 nm in wavelength. Perceived color is a function of three variables: spectral properties of the object, both absorptive and reflective; spectral properties of the source of illumination; and visual characteristics of the observer.

Two objects are said to have a color match for a particular source of illumination when an observer cannot detect a color difference. Where a pair of objects exhibit a color match for one source of illumination and not another, they constitute a metameric pair. Color matches of two objects occur for all sources of illumination if the absorption and reflectance spectra of the two objects are identical.

Achromicity or colorlessness is one extreme of any color scale for transmission of light. It implies the complete absence of color, and therefore the visible spectrum of the object lacks absorbances. For practical purposes, the observer in this case perceives little if any absorption taking place in the visible spectrum.

**Color Attributes**— Because the sensation of color has both a subjective and an objective part, color cannot be described solely in spectrophotometric terms. The common attributes of color therefore cannot be given a one-to-one correspondence with spectral terminology.

Three attributes are commonly used to identify a color: (1) hue, or the quality by which one color family is distinguished from another, such as red, yellow, blue, green, and intermediate terms; (2) value, or the quality that distinguishes a light color from a dark one; and (3) chroma, or the quality that distinguishes a strong color from a weak one, or the extent to which a color differs from a gray of the same value.

The three attributes of color may be used to define a three-dimensional color space in which any color is located by its coordinates. The color space chosen is a visually uniform one if the geometric distance between two colors in the color space is directly a measure of the color distance between them. Cylindrical coordinates are often conveniently chosen. Points along the long axis represent value from dark to light or black to white and have indeterminate hue and no chroma. Focusing on a cross-section perpendicular to the value axis, hue is determined by the angle about the long axis and chroma is determined by the distance from the long axis. Red, yellow, green, blue, purple, and intermediate hues are given by different angles. Colors along a radius of a cross-section have the same hue, which become more intense farther out. For example, colorless or achromatic water has indeterminate hue, high value, and no chroma. If a colored solute is added, the water takes on a particular hue. As more is added, the color becomes darker, more intense, or deeper; i.e., the chroma generally increases and value decreases. If, however, the solute is a neutral color, i.e., gray, the value decreases, no increase in chroma is observed, and the hue remains indeterminate.

Laboratory spectroscopic measurements can be converted to measurements of the three color attributes. Spectroscopic results for three chosen lights or stimuli are weighted by three distribution functions to yield the tristimulus values, X, Y, Z (see [1061 Color—Instrumental Measurement](#)). The distribution functions were determined in color matching experiments with human subjects.

The tristimulus values are not coordinates in a visually uniform color space; however, several transformations have been proposed that are close to being uniform, one of which is given in the chapter cited ([1061 Color—Instrumental Measurement](#)). The value is often a function of only the Y value. Obtaining uniformity in the chroma-hue subspace has been less satisfactory. In a practical sense, this means in visual color comparison that if two objects differ significantly in hue, deciding which has a higher chroma becomes difficult. This points out the importance of matching standard to sample color as closely as possible, especially for the attributes of hue and chroma.

**Color Determination and Standards**— The perception of color and color matches is dependent on conditions of viewing and illumination. Determinations should be made using diffuse, uniform illumination under conditions that reduce shadows and nonspectral reflectance to a minimum. The surface of powders should be smoothed with gentle pressure so that a planar surface free from irregularities is presented. Liquids should be compared in matched color-comparison tubes, against a white background. If results are found to vary with illumination, those obtained in natural or artificial daylight are to be considered correct. Instead of visual determination, a suitable instrumental method may be used.

Colors of standards should be as close as possible to those of test specimens for quantifying color differences. Standards for opaque materials are available as sets of color chips that are arranged in a visually uniform space.<sup>2</sup> Standards identified by a letter for matching the colors of fluids can be prepared according to the accompanying table. To prepare the matching fluid required, pipet the prescribed volumes of the colorimetric test solutions [see under Colorimetric Solutions (CS) in the section Reagents, Indicators, and Solutions] and water into one of the matching containers, and mix the solution in the container. Make the comparison as directed in the individual monograph, under the viewing conditions previously described. The matching fluids, or other combinations of the colorimetric solutions, may be used in very low concentrations to measure deviation from achromicity.

Matching Fluids

Matching Fluid	Parts of Cobaltous Chloride CS	Parts of Ferric Chloride CS	Parts of Cupric Sulfate CS	Parts of Water
A	0.1	0.4	0.1	4.4
B	0.3	0.9	0.3	3.5
C	0.1	0.6	0.1	4.2
D	0.3	0.6	0.4	3.7
E	0.4	1.2	0.3	3.1
F	0.3	1.2	0.0	3.5
G	0.5	1.2	0.2	3.1
H	0.2	1.5	0.0	3.3
I	0.4	2.2	0.1	2.3
J	0.4	3.5	0.1	1.0
K	0.5	4.5	0.0	0.0

#### 641 COMPLETENESS OF SOLUTION

Place the quantity of the substance specified in the individual monograph in a meticulously cleansed, glass-stoppered, 10-mL glass cylinder approximately 13 mm × 125 mm in size. Using the solvent that is specified in the monograph or on the label of the product, fill the cylinder almost to the constriction at the neck. Shake gently to effect solution: the solution is not less clear than an equal volume of the same solvent contained in a similar vessel and examined similarly.

USP32-NF27 Page 239

#### 643 TOTAL ORGANIC CARBON

Total organic carbon (TOC) is an indirect measure of organic molecules present in pharmaceutical waters measured as carbon. Organic molecules are introduced into the water from the source water, from purification and distribution system materials, and from biofilm growing in the system. TOC can also be used as a process control attribute to monitor the performance of unit operations comprising the purification and distribution system.

A number of acceptable methods exist for analyzing TOC. This chapter does not limit or prevent alternative technologies from being used, but provides guidance on how to qualify these analytical technologies for use as well as guidance on how to interpret instrument results for use as a limit test. The Standard Solution is a theoretically easy-to-oxidize solution that gives an instrument response at the attribute limit. The analytical technology is qualified by challenging the capability of the instrument using a theoretically difficult to oxidize solution in the system suitability portion of the method.

Analytical technologies utilized to measure TOC share the objective of completely oxidizing the organic molecules in an aliquot of sample water to carbon dioxide (CO<sub>2</sub>), measuring the resultant CO<sub>2</sub> levels, and expressing this response as carbon concentration. All technologies must discriminate between the inorganic carbon, which may be present in the water from sources such as dissolved CO<sub>2</sub> and bicarbonate, and the CO<sub>2</sub> generated from the oxidation of organic molecules in the sample.

Two general approaches are used to measure TOC. One approach determines TOC by subtracting the measured inorganic carbon (IC) from the measured total carbon (TC), which is the sum of organic carbon and inorganic carbon:

$$TOC = TC - IC.$$

The other approach first purges the IC from the sample before any carbon measurement is performed. However, this IC purging step also purges some of the organic molecules, which can be re trapped, oxidized to CO<sub>2</sub>, and quantitated as purgeable organic carbon (POC). The remaining organic matter in the sample is also oxidized to CO<sub>2</sub> and quantitated as nonpurgeable organic carbon (NPOC). In this approach, TOC is the sum of POC and NPOC:

$$TOC = POC + NPOC.$$

In pharmaceutical waters, the amount of POC is negligible and can be discounted. Therefore, for the purpose of this methodology, NPOC is equivalent to TOC.

Apparatus Requirements— This test method is performed either as an on-line test or as an off-line laboratory test using a calibrated instrument. The suitability of the apparatus must be periodically demonstrated as described below. In addition, it must have a manufacturer's specified limit of detection of 0.05 mg of carbon per L (0.05 ppm of carbon) or lower.

#### USP Reference Standards (11)—USP 1,4-Benzquinone RS, USP Sucrose RS.

Reagent Water— Use water having a TOC level of not more than 0.10 mg per L. [note—A conductivity requirement may be necessary to ensure method reliability.]

Glassware Preparation— Organic contamination of glassware results in higher TOC values. Therefore, use glassware and sample containers that have been scrupulously cleaned of organic residues. Any method that is effective in removing organic matter can be used (see [Cleaning Glass Apparatus \(1051\)](#)). Use Reagent Water for the final rinse.

Standard Solution— Unless otherwise directed in the individual monograph, dissolve in the Reagent Water an accurately weighed quantity of USP Sucrose RS, to obtain a solution having a concentration of about 1.2 mg of sucrose per L (0.50 mg of carbon per liter).

Test Solution— [note—Use extreme caution when obtaining samples for TOC analysis. Water samples can be easily contaminated during the process of sampling and transportation to a testing facility.] Collect the Test Solution in a tight container with minimal head space, and test in a timely manner to minimize the impact of organic contamination from the closure and container.

System Suitability Solution— Dissolve in Reagent Water an accurately weighed quantity of USP 1,4-Benzquinone RS to obtain a solution having a concentration of 0.75 mg per L (0.50 mg of carbon per liter).

Reagent Water Control— Use a suitable quantity of Reagent Water obtained at the same time as that used in the preparation of the Standard Solution and the System Suitability Solution.

Other Control Solutions— Prepare appropriate reagent blank solutions or other specified solutions needed for establishing the apparatus baseline or for calibration adjustments following the manufacturer's instructions, and run the appropriate blanks to zero the instrument.

System Suitability— Test the Reagent Water Control in the apparatus, and record the response,  $r_w$ . Repeat the test using the Standard Solution, and record the response,  $r_S$ . Calculate the corrected Standard Solution response, which is also the limit response, by subtracting the Reagent Water Control response from the response of the Standard Solution. The theoretical limit of 0.50 mg of carbon per L is equal to the corrected Standard Solution response,  $r_S - r_w$ . Test the System Suitability Solution in the apparatus, and record the response,  $r_{SS}$ . Calculate the corrected System Suitability Solution response by subtracting the Reagent Water Control response from the response of the System Suitability Solution,  $r_{SS} - r_w$ . Calculate the response efficiency for the System Suitability Solution by the formula:

$$100[(r_{SS} - r_w) / (r_S - r_w)].$$

The system is suitable if the response efficiency is not less than 85% and not more than 115% of the theoretical response.

Procedure— Perform the test on the Test Solution, and record the response,  $r_U$ . The Test Solution meets the requirements if  $r_U$  is not more than the limit response,  $r_S - r_w$ . This method also can be performed alternatively using on-line instrumentation that has been appropriately calibrated, standardized, and has demonstrated acceptable system suitability. The acceptability of such on-line instrumentation for quality attribute testing is dependent on its location(s) in the water system. These instrument location(s) and responses must reflect the quality of the water used.

Auxiliary Information— Please [check for your question in the FAQs](#) before contacting USP.

#### 645 WATER CONDUCTIVITY

Electrical conductivity in water is a measure of the ion-facilitated electron flow through it. Water molecules dissociate into ions as a function of pH and temperature and result in a very predictable conductivity. Some gases, most notably carbon dioxide, readily dissolve in water and interact to form ions, which predictably affect conductivity as well as pH. For the purpose of this discussion, these ions and their resulting conductivity can be considered intrinsic to the water.

Water conductivity is also affected by the presence of extraneous ions. The extraneous ions used in modeling the conductivity specifications described below are the chloride and sodium ions. The conductivity of the ubiquitous chloride ion (at the theoretical endpoint concentration of 0.47 ppm when it was a required attribute test in USP XXII and earlier revisions) and the ammonium ion (at the limit of 0.3 ppm) represent a major portion of the allowed water impurity level. A balancing quantity of cations, such as sodium ions, is included in this allowed impurity level to maintain electroneutrality. Extraneous ions such as these may have significant impact on the water's chemical purity and suitability for use in pharmaceutical applications. The procedure described in the section Bulk Water is designed for measuring the conductivity of waters such as Purified Water, Water for Injection, Water for Hemodialysis, and the condensate of Pure Steam produced in bulk. For water packaged in bulk but manufactured elsewhere or for Sterile Purified Water, Sterile Water for Injection, Sterile Water for Inhalation, and Sterile Water for Irrigation, some additional conductivity tests may be required. Such tests are described in the section Packaged Water.

Online conductivity testing provides real-time measurements and opportunities for real-time process control, decision, and intervention. Precaution should be taken while collecting water samples for off-line conductivity measurements. The sample may be affected by the sampling method, the sampling container, and environmental factors such as ambient carbon dioxide concentration and organic vapors.

#### INSTRUMENT SPECIFICATIONS AND OPERATING PARAMETERS

Water conductivity must be measured accurately using calibrated instrumentation. The conductivity cell constant, a factor that represents the geometrical properties of the conductivity sensor, must be known within  $\pm 2\%$ . The cell constant can be verified directly by using a solution of known or traceable conductivity, or indirectly by comparing the instrument reading taken with the conductivity sensor in question to readings from a conductivity sensor of known or traceable cell constant.

Meter calibration is accomplished by replacing the conductivity sensor with NIST (or equivalent local national authority) -traceable precision resistors (accurate to  $\pm 0.1\%$  of the stated value) or an equivalently accurate adjustable resistance device, such as a Wheatstone Bridge, to give a predicted instrument response. Each scale on the meter may require separate calibration prior to use. The frequency of recalibration is a function of instrument design, degree of use, etc. However, because some multiple-scale instruments have a single calibration adjustment, recalibration may be required between each use of a different scale. Excluding the conductivity sensor cell constant accuracy, the instrument accuracy must be  $\pm 0.1 \mu\text{S}/\text{cm}$ .

In order to increase the measurement accuracy on the conductivity ranges used, which can be large, and to ensure a complete equipment calibration, it is suggested that periodic verification of the entire equipment be performed. This could be done by comparing the conductivity/resistivity values displayed by the measuring equipment with those of an external calibrated conductivity-measuring device. The two nontemperature-compensated conductivity or resistivity values must be equivalent to within  $\pm 20\%$  of each other, or at a difference that is acceptable on the basis of product water criticality and/or the water conductivity ranges in which the measurements are taken. The two conductivity sensors should be positioned close enough together to measure the same water sample in the same environmental conditions.

In addition to the verification method performed in non-temperature-compensated mode, a similar verification performed in temperature-compensated mode could be performed to ensure an appropriate accuracy of the equipment when such a mode is used for trending or other purposes.

Because temperature has a substantial impact on conductivity readings of specimens at high and low temperatures, many instruments automatically correct the actual reading to display the value that theoretically would be observed at the nominal temperature of  $25^\circ\text{C}$ . This is typically done using a temperature sensor embedded in the conductivity sensor and an algorithm in the instrument's circuitry. This temperature compensation algorithm may not be accurate. Conductivity values used in this method are nontemperature-compensated measurements. Temperature measurement is required for the performance of the Stage 1 test. It may be made using the temperature sensor embedded in the conductivity cell sensor.

An external temperature sensor positioned near the conductivity sensor is also acceptable. Accuracy of the temperature measurement must be  $\pm 2^\circ\text{C}$ .

#### BULK WATER

The procedure below shall be performed using instrumentation that has been calibrated, has conductivity sensor cell constants that have been accurately determined, and has temperature compensation function that has been disabled. For both online and offline measurements, the suitability of instrumentation for quality control testing is also dependent on the sampling location(s) in the water system. The selected sampling instrument location(s) must reflect the quality of the water used.

The combined conductivities of the intrinsic and extraneous ions vary as a function of pH and are the basis for the conductivity specifications described in the Stage 3—pH and Conductivity Requirements table and used when performing Stage 3 of the test method. Two preliminary stages are included in the test method. If the test conditions and conductivity limits are met at either of these preliminary stages, the water meets the requirements of this test. Proceeding to the third stage of the test in these circumstances is unnecessary. Only in the event of failure at the final test stage is the sample judged noncompliant with the requirements of the test.

## Procedure

## Stage 1

Stage 1 is intended for online measurement or may be performed offline in a suitable container.

1. Determine the temperature of the water and the conductivity of the water using a nontemperature-compensated conductivity reading.
2. Using the [Stage 1—Temperature and Conductivity Requirements](#) table, find the temperature value that is not greater than the measured temperature, i.e., the next lower temperature. The corresponding conductivity value on this table is the limit. [note—Do not interpolate.]
3. If the measured conductivity is not greater than the table value, the water meets the requirements of the test for conductivity. If the conductivity is higher than the table value, proceed with Stage 2.

Stage 1—Temperature and Conductivity Requirements  
(for nontemperature-compensated conductivity measurements only)

Temperature	Conductivity Requirement ( $\mu\text{S}/\text{cm}$ )
0	0.6
5	0.8
10	0.9
15	1.0
20	1.1
25	1.3
30	1.4
35	1.5
40	1.7
45	1.8
50	1.9
55	2.1
60	2.2
65	2.4
70	2.5
75	2.7
80	2.7
85	2.7
90	2.7
95	2.9
100	3.1

## Stage 2

4. Transfer a sufficient amount of water (100 mL or more) to a suitable container, and stir the test specimen. Adjust the temperature, if necessary, and, while maintaining it at  $25 \pm 1^\circ$ , begin vigorously agitating the test specimen while periodically observing the conductivity. When the change in conductivity (due to uptake of atmospheric carbon dioxide) is less than a net of 0.1  $\mu\text{S}/\text{cm}$  per 5 minutes, note the conductivity.

5. If the conductivity is not greater than 2.1  $\mu\text{S}/\text{cm}$ , the water meets the requirements of the test for conductivity. If the conductivity is greater than 2.1  $\mu\text{S}/\text{cm}$ , proceed with Stage 3.

## Stage 3

6. Perform this test within approximately 5 minutes of the conductivity determination in Step 5, while maintaining the sample temperature at  $25 \pm 1^\circ$ . Add a saturated potassium chloride solution to the same water sample (0.3 mL per 100 mL of the test specimen), and determine the pH to the nearest 0.1 pH unit, as directed under [pH \(791\)](#).
7. Referring to the [Stage 3—pH and Conductivity Requirements](#) table, determine the conductivity limit at the measured pH value. If the measured conductivity in Step 4 is not greater than the conductivity requirements for the pH determined in Step 6, the water meets the requirements of the test for conductivity. If either the measured conductivity is greater than this value or the pH is outside the range of 5.0 to 7.0, the water does not meet the requirements of the test for conductivity.

Stage 3—pH and Conductivity Requirements  
(for atmosphere- and temperature-equilibrated samples only)

pH	Conductivity Requirement ( $\mu\text{S}/\text{cm}$ )
5.0	4.7
5.1	4.1
5.2	3.6
5.3	3.3
5.4	3.0
5.5	2.8
5.6	2.6
5.7	2.5
5.8	2.4
5.9	2.4
6.0	2.4
6.1	2.4
6.2	2.5
6.3	2.4
6.4	2.3
6.5	2.2

6.6	2.1
6.7	2.6
6.8	3.1
6.9	3.8
7.0	4.6

## PACKAGED WATER

The procedure and test limits are intended for water packaged in bulk but manufactured elsewhere or for Sterile Purified Water, Sterile Water for Injection, Sterile Water for Inhalation, and Sterile Water for Irrigation. All these waters are derived from Purified Water or Water for Injection, and therefore have been determined to be compliant with the Bulk Water requirements before being stored in the container. The specification provided represents the maximum allowable conductivity value, taking into consideration the limitation of the measurement method and reasonable container leaching. Such specification and the sampling volume choices should be defined and validated on the basis of the intended purpose of the water.

## Procedure

Transfer a sufficient amount of water to a suitable container, and stir the test specimen. Adjust the temperature, if necessary, and, while maintaining it at  $25 \pm 1^\circ$ , begin vigorously agitating the test specimen while periodically observing the conductivity. When the change in conductivity (due to uptake of ambient carbon dioxide) is less than a net of  $0.1 \mu\text{S}/\text{cm}$  per 5 minutes, note the conductivity.

For containers with a nominal volume of 10 mL or less, if the conductivity is not greater than  $25 \mu\text{S}/\text{cm}$ , the water meets the requirements. For containers with a nominal volume greater than 10 mL, if the conductivity is not greater than  $5 \mu\text{S}/\text{cm}$ , the water meets the requirements.

Auxiliary Information— Please [check for your question in the FAQs](#) before contacting USP.

## 651 CONGEALING TEMPERATURE

The temperature at which a substance passes from the liquid to the solid state upon cooling is a useful index to purity if heat is liberated when the solidification takes place, provided that any impurities present dissolve in the liquid only, and not in the solid. Pure substances have a well-defined freezing point, but mixtures generally freeze over a range of temperatures. For many mixtures, the congealing temperature, as determined by strict adherence to the following empirical methods, is a useful index of purity. The method for determining congealing temperatures set forth here is applicable to substances that melt between  $-20^\circ$  and  $150^\circ$ , the range of the thermometer used in the bath. The congealing temperature is the maximum point (or lacking a maximum, the point of inflection) in the temperature-time curve.

Apparatus— Assemble an apparatus similar to that [illustrated](#).

Congealing Temperature Apparatus

in which the container for the substance is a 25- x 100-mm test tube. This is provided with a suitable, short-range thermometer suspended in the center, and a wire stirrer, about 30 cm long, bent at its lower end into a horizontal loop around the thermometer. Use a thermometer having a range not exceeding  $30^\circ$ , graduated in  $0.1^\circ$  divisions, and calibrated for, but not

used at, 76-mm immersion. A suitable series of thermometers, covering a range from  $-20^{\circ}$  to  $+150^{\circ}$ , is available as the ASTM E1 series 89C through 96C. Other temperature-measuring devices may be used if they are validated for this procedure (see [Thermometers \(21\)](#)). Dimensions should be within  $\pm 20\%$  of those given in the illustration.

The specimen container is supported, by means of a cork, in a suitable water-tight cylinder about 50 mm in internal diameter and 11 cm in length. The cylinder, in turn, is supported in a suitable bath sufficient to provide not less than a 37-mm layer surrounding the sides and bottom of the cylinder. The outside bath is provided with a suitable thermometer.

**Procedure**— Melt the substance, if a solid, at a temperature not exceeding  $20^{\circ}$  above its expected congealing point, and pour it into the test tube to a height of 50 to 57 mm. Assemble the apparatus with the bulb of the test tube thermometer immersed halfway between the top and bottom of the specimen in the test tube. Fill the bath to about 12 mm from the top of the tube with suitable fluid at a temperature  $4^{\circ}$  to  $5^{\circ}$  below the expected congealing point.

In case the substance is a liquid at room temperature, carry out the determination using a bath temperature about  $15^{\circ}$  below the expected congealing point.

When the test specimen has cooled to about  $5^{\circ}$  above its expected congealing point, adjust the bath to a temperature  $7^{\circ}$  to  $8^{\circ}$  below the expected congealing point. Stir the specimen continuously during the remainder of the test by moving the loop up and down between the top and bottom of the specimen, at a regular rate of 20 complete cycles per minute.

Congelation frequently may be induced by rubbing the inner walls of the test tube with the thermometer, or by introducing a small fragment of the previously congealed substance. Pronounced supercooling may cause deviation from the normal pattern of temperature changes. If the latter occurs, repeat the test, introducing small particles of the material under test in solid form at  $1^{\circ}$  intervals as the temperature approaches the expected congealing point.

Record the reading of the test tube thermometer every 30 seconds. Continue stirring only so long as the temperature is gradually falling, stopping when the temperature becomes constant or starts to rise slightly. Continue recording the temperature in the test tube every 30 seconds for at least 3 minutes after the temperature again begins to fall after remaining constant.

The average of not less than four consecutive readings that lie within a range of  $0.2^{\circ}$  constitutes the congealing temperature. These readings lie about a point of inflection or a maximum, in the temperature-time curve, that occurs after the temperature becomes constant or starts to rise and before it again begins to fall. The average to the nearest  $0.1^{\circ}$  is the congealing temperature.

**Auxiliary Information**— Please [check for your question in the FAQs](#) before contacting USP.

## 660 CONTAINERS—GLASS

Glass containers for pharmaceutical use are intended to come into direct contact with pharmaceutical preparations. Glass used for pharmaceutical containers is either a borosilicate (neutral) glass or a soda-lime glass. Borosilicate glass contains a significant amount of boric oxide, aluminum oxide, and alkali and/or alkaline earth oxides. Borosilicate glass has a high hydrolytic resistance due to the chemical composition of the glass itself; it is classified as Type I glass. Soda-lime glass is a silica glass containing alkali metal oxides. Soda-lime glass has a moderate hydrolytic resistance due to the chemical composition of the glass itself; it is classified as Type III glass. The inner surface of glass containers may be treated, for example, to improve hydrolytic resistance. The treatment of Type III soda-lime glass containers will raise their hydrolytic resistance from a moderate to a high level, changing the classification of the glass to Type II.

The outer surface of glass containers may be treated to reduce friction or for protection against abrasion or breakage. The treatment of the outer surface does not come into contact with the inner surface of the container. Glass may be colored to provide protection from light or may have a coating applied to the outer surface. Such containers will meet the requirements for Light Transmission under [Containers—Permeation \(671\)](#). A clear and colorless or a translucent container that is made light-resistant by means of an opaque enclosure (see Light-Resistant Container in Preservation, Packaging, Storage, and Labeling under the General Notices) is exempt from the requirements for Light Transmission.

The quality of glass containers is defined by measuring their resistance to chemical attack. In addition, Type I containers for aqueous parenteral preparations are tested for arsenic release, and colored glass containers are tested for light transmission.

### CHEMICAL RESISTANCE

The following tests are designed to determine the resistance to water attack of new (not previously used) glass containers. The degree of attack is determined by the amount of alkali released from the glass under the influence of the attacking medium under the conditions specified. This quantity of alkali is extremely small in the case of the more resistant glasses, thus calling for particular attention to all details of the tests and the use of apparatus of high quality and precision. The tests should be conducted in an area relatively free from fumes and excessive dust.

**Glass Types**— Glass containers suitable for packaging Pharmacopeial preparations may be classified as in [Table 1](#) on the basis of the tests set forth in this section. Containers of Type I borosilicate glass are generally used for preparations that are intended for parenteral administration. Containers of Type I glass, or of Type II glass (i.e., soda-lime glass that is suitably dealkalized) are usually used for packaging acidic and neutral parenteral preparations. Type I glass containers, or Type II glass containers (where stability data demonstrate their suitability), are used for alkaline parenteral preparations. Type III soda-lime glass containers usually are not used for parenteral preparations, except where suitable stability test data indicate that Type III glass is satisfactory for the parenteral preparations that are packaged therein.

Table 1. Glass Types

Type	General Description	Type of Test
I	Highly resistant, borosilicate glass	Powdered Glass
II	Treated soda-lime glass	Water Attack
III	Soda-lime glass	Powdered Glass

### Apparatus—

**Autoclave**— For these tests, use an autoclave capable of maintaining a temperature of  $121 \pm 2.0^{\circ}$ , equipped with a thermometer, a pressure gauge, a vent cock, and a rack adequate to accommodate at least 12 test containers above the water level.

**Mortar and Pestle**— Use a hardened-steel mortar and pestle, made according to the specifications in [Figure 1](#).

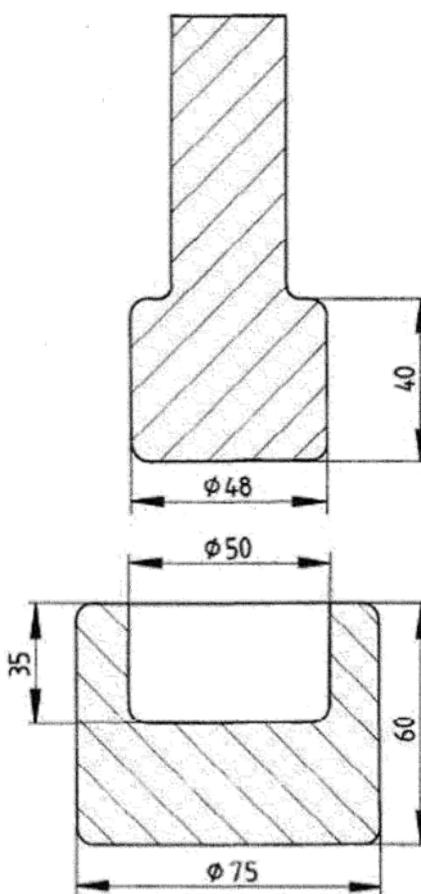

Figure 1. Mortar and Pestle for Pulverizing Glass<sup>1</sup>

Other Equipment— Also required are 20.3-cm (8-inch) sieves made of stainless steel, including the Nos. 20, 40, and 50 sieves, along with the pan and cover (see Sizes of Standard Sieve Series in Range of Interest under [Particle Size Distribution Estimation by Analytical Sieving \(786\)](#)); 250-mL conical flasks made of resistant glass aged as specified; a 900-g (2-lb) hammer; a permanent magnet; a desiccator; and an adequate volumetric apparatus.

#### Reagents—

High-Purity Water— The water used in these tests has a conductivity at 25°, as measured in an in-line cell just prior to dispensing, of not greater than 0.15  $\mu$ S per cm (6.67 Megohm-cm). There must also be an assurance that this water is not contaminated by copper or its products (e.g., copper pipes, stills, or receivers). The water may be prepared by passing distilled water through a deionizer cartridge packed with a mixed bed of nuclear-grade resin, then through a cellulose ester membrane having openings not exceeding 0.45  $\mu$ m.<sup>2</sup> Do not use copper tubing. Flush the discharge lines before water is dispensed into test vessels. When the low conductivity specification can no longer be met, replace the deionizer cartridge.

Carbon Dioxide-Free Water— This is [Purified Water](#) that has been boiled vigorously for 5 minutes or more and allowed to cool while protected from absorption of carbon dioxide from the atmosphere, or [Purified Water](#) that has a resistivity of not less than 18 Mohm-cm.

Methyl Red Solution (Powdered Glass Test and Water Attack at 121°)— Dissolve 24 mg of methyl red sodium in [Purified Water](#) to make 100 mL. If necessary, neutralize the solution with 0.02 N sodium hydroxide, or acidify it with 0.02 N sulfuric acid so that the titration of 100 mL of High-Purity Water, containing 5 drops of indicator, does not require more than 0.020 mL of 0.020 N sodium hydroxide to effect the color change of the indicator, which should occur at a pH of 5.6.

Methyl Red Solution (Surface Glass Test)— Dissolve 50 mg of methyl red solution in 1.86 mL of 0.1 M sodium hydroxide and 50 mL of ethanol (96%) and dilute to 100 mL with [Purified Water](#). To test for sensitivity, add 100 mL of Carbon Dioxide-Free Water and 0.05 mL of 0.02 M hydrochloric acid to 0.1 mL of the methyl red solution (the solution should be red). Not more than 0.1 mL of 0.02 M sodium hydroxide is required to change the color to yellow. Color change: pH 4.4 (red) to pH 6.0 (yellow).

#### Powdered Glass Test

Rinse thoroughly with [Purified Water](#) six or more containers selected at random, and dry them with a current of clean, dry air. Crush the containers into fragments about 25 mm in size, divide about 100 g of the coarsely crushed glass into three approximately equal portions, and place one of the portions in the special mortar. With the pestle in place, crush the glass further by striking 3 or 4 blows with the hammer. Nest the sieves, and empty the mortar into the No. 20 sieve. Repeat the operation on each of the two remaining portions of glass, emptying the mortar each time into the No. 20 sieve. Shake the sieves for a short time, then remove the glass from the Nos. 20 and 40 sieves, and again crush and sieve as before. Repeat again this crushing and sieving operation. Empty the receiving pan, reassemble the nest of sieves, and shake by mechanical means for 5 minutes or by hand for an equivalent length of time. Transfer the portion retained on the No. 50 sieve, which should weigh in excess of 10 g, to a closed container, and store in a desiccator until used for the test.

Spread the specimen on a piece of glazed paper, and pass a magnet through it to remove particles of iron that may be introduced during the crushing. Transfer the specimen to a 250-mL conical flask of resistant glass, and wash it with six 30-mL portions of acetone, swirling each time for about 30 seconds, and carefully decanting the acetone. After washing, the specimen should be free from agglomerations of glass powder, and the surface of the grains should be practically free from adhering fine particles. Dry the flask and contents for 20 minutes at 140°, transfer the grains to a weighing bottle, and cool in a desiccator. Use the test specimen within 48 hours after drying.

Procedure— Transfer 10.00 g of the prepared specimen, accurately weighed, to a 250-mL conical flask that has been digested (aged) previously with High-Purity Water in a bath at 90° for at least 24 hours or at 121° for 1 hour. Add 50.0 mL of High-Purity Water to this flask and to one similarly prepared to provide a blank. Cap all flasks with borosilicate glass beakers that previously have been treated as described for the flasks and that are of such size that the bottoms of the beakers fit snugly down on the top rims of the containers. Place the containers in the autoclave, and close it securely, leaving the vent cock open. Heat until steam issues vigorously from the vent cock, and continue heating for 10 minutes. Close the vent cock, and adjust the temperature to 121°, taking 19 to 23 minutes to reach the desired temperature. Hold the temperature at 121 ± 2.0° for 30 minutes, counting from the time this temperature is reached. Reduce the heat so that the autoclave cools and comes to atmospheric pressure in 38 to 46 minutes, being vented as necessary to prevent the formation of a vacuum. Cool the flask at once in running water, decant the water from the flask into a suitably cleansed vessel, and wash the residual powdered glass with four 15-mL portions of High-Purity Water, adding the decanted washings to the main portion. Add 5 drops of Methyl Red Solution, and titrate immediately with 0.020 N sulfuric acid. If the volume of titrating solution is expected to be less than 10 mL, use a microburet. Record the volume of 0.020 N sulfuric acid used to neutralize the extract from 10 g of the prepared specimen of glass,

corrected for a blank. The volume does not exceed that indicated in [Table 2](#) for the type of glass concerned.

Table 2. Test Limits for Powdered Glass Test

Type	General Description	Type of Test	Limits	
			Size, mL of 0.020 N Acid	
I	Highly resistant, borosilicate glass	Powdered Glass	All	1.0
III	Soda-lime glass	Powdered Glass	All	8.5

a The description applies to containers of this type of glass usually available.

b Size indicates the overflow capacity of the container.

#### Surface Glass Test

Determination of the Filling Volume— The filling volume is the volume to be filled with [Purified Water](#) in the container for the purpose of the test. For vials and bottles the filling volume is 90% of the brimful capacity. For ampules it is the volume up to the height of the shoulder.

Vials and Bottle— Select, at random, 6 containers from the sample lot, or 3 if their capacity exceeds 100 mL, and remove any dirt or debris. Weigh the empty containers with an accuracy of 0.1 g. Place the containers on a horizontal surface, and fill them with [Purified Water](#) to about the rim edge, avoiding overflow and introduction of air bubbles. Adjust the liquid levels to the brimful line. Weigh the filled containers to obtain the mass of the water, expressed to 2 decimal places, for containers having a nominal volume less or equal to 30 mL, and expressed to 1 decimal place for containers having a nominal volume greater than 30 mL. Calculate the mean value of the brimful capacity in mL, and multiply it by 0.9. This volume, expressed to 1 decimal place, is the filling volume for the particular container lot.

Ampules— Place at least 6 dry ampules on a flat, horizontal surface, and fill them with [Purified Water](#) from a buret until the water reaches point A, where the body of the ampule decreases to the shoulder of the ampule (see [Figure 2](#)). Read the capacities, expressed to 2 decimal places, and calculate the mean value. This volume, expressed to 1 decimal place, is the filling volume for the particular ampule lot. The filling volume may also be determined by weighing.

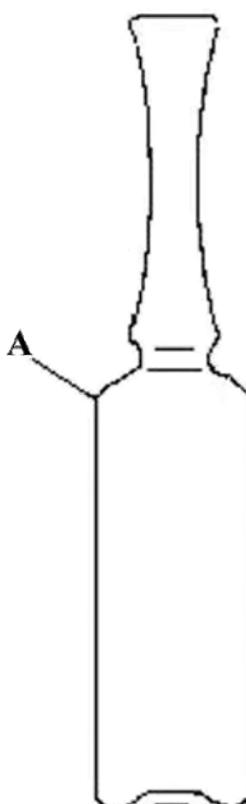

Figure 2. Filling Volumes of Ampules (up to point A)

Test— The determination is carried out on unused containers. The volumes of the test liquid necessary for the final determination are indicated in [Table 3](#).

Table 3. Volume of Test Liquid and Number of Titrations

Filling Volume (mL)	Volume of Test Liquid for One Titration (mL)	Number of Titrations
Up to 3	25.0	1
Above 3 and up to 30	50.0	2
Above 30 and up to 100	100.0	2
Above 100	100.0	3

Cleaning— Remove any debris or dust. Shortly before the test, rinse each container carefully at least twice with [Purified Water](#), and allow to stand. Immediately before testing, empty

the containers, rinse once with [Purified Water](#), then with Carbon Dioxide-Free Water and allow to drain. Complete the cleaning procedure from the first rinsing in not less than 20 minutes and not more than 25 minutes. Heat closed ampules in a water bath or in an air-oven at about 50° for approximately 2 minutes before opening. Do not rinse before testing.

**Filling and Heating**— The containers are filled with Carbon Dioxide-Free Water up to the filling volume. Containers in the form of cartridges or prefilled syringes are closed in a suitable manner with material that does not interfere with the test. Each container, including ampules, shall be loosely capped with an inert material such as a dish of neutral glass or aluminum foil previously rinsed with [Purified Water](#). Place the containers on the tray of the autoclave.

Place the tray in the autoclave containing a quantity of water such that the tray remains clear of the water. Close the autoclave, and carry out the following operations:

1. heat the autoclave to 100° and allow the steam to issue from the vent cock for 10 minutes;
2. close the vent cock and raise the temperature from 100° to 121° at a rate of 1° per minute;
3. maintain the temperature at 121 ± 1° for 60 ± 1 minutes;
4. lower the temperature from 121° to 100° at a rate of 0.5° per minute, venting to prevent a vacuum;
5. do not open the autoclave before it has cooled down to 95°;
6. remove the containers from the autoclave using normal precautions, place them in a water bath at 80°, and run cold tap water, taking care that the water does not contact the loose foil caps to avoid contamination of the extraction solution;
7. cooling time does not exceed 30 minutes.

The extraction solutions are analyzed by titration according to the method described below.

**Method**— Carry out the titration within 1 hour of removal of the containers from the autoclave.

Combine the liquids obtained from the containers, and mix. Introduce the prescribed volume indicated in [Table 3](#) into a conical flask. Place the same volume of Carbon Dioxide-Free Water into a second similar flask as a blank. Add 0.05 mL of Methyl Red Solution to each flask for each 25 mL of liquid. Titrate the blank with 0.01 M hydrochloric acid. Titrate the test liquid with the same acid until the color of the resulting solution is the same as that obtained for the blank. Subtract the value found for the blank titration from that found for the test liquid, and express the results in mL of 0.01 M hydrochloric acid per 100 mL. Express titration values of less than 1.0 mL to 2 decimal places and titration values of more than or equal to 1.0 mL to 1 decimal place.

**Limits**— The results, or the average of the results if more than one titration is performed, are not greater than the values stated in [Table 4](#).

Table 4. Test Limits for Surface Glass Test

Filling Volume (mL)	Maximum Volume of 0.01 M HCl per 100 mL of Test Liquid (mL)	
	Types I and II	Type III
Up to 1	2.0	20.0
Above 1 and Up to 2	1.8	17.6
Above 2 and Up to 5	1.3	13.2
Above 5 and Up to 10	1.0	10.2
Above 10 and Up to 20	0.80	8.1
Above 20 and Up to 50	0.60	6.1
Above 50 and Up to 100	0.50	4.8
Above 100 and Up to 200	0.40	3.8
Above 200 and Up to 500	0.30	2.9
Above 500	0.20	2.2

Water Attack at 121°

**Option**— The Water Attack at 121° test can be used to qualify Type II glass.

Rinse thoroughly 3 or more containers, selected at random, twice with High-Purity Water.

**Procedure**— Fill each container to 90% of its overflow capacity with High-Purity Water, and proceed as directed for Procedure under Powdered Glass Test, beginning with “Cap all flasks,” except that the time of autoclaving shall be 60 minutes instead of 30 minutes, and ending with “to prevent the formation of a vacuum.” Empty the contents from 1 or more containers into a 100-mL graduated cylinder, combining, in the case of smaller containers, the contents of several containers to obtain a volume of 100 mL. Place the pooled specimen

in a 250-mL conical flask of resistant glass, add 5 drops of Methyl Red Solution, and titrate, while warm, with 0.020 N sulfuric acid. Complete the titration within 60 minutes after opening the autoclave. Record the volume of 0.020 N sulfuric acid used, corrected for a blank obtained by titrating 100 mL of High-Purity Water at the same temperature and with the same amount of indicator. The volume does not exceed that indicated in [Table 5](#).

Table 5. Test Limit for Water Attack at 121°

Type	General Description <sup>a</sup>	Type of Test	Limits	
			Size, <sup>b</sup> mL	mL of 0.020 N Acid
II	Treated soda-lime glass	Water Attack	100 or less	0.7
			Over 100	0.2

<sup>a</sup> The description applies to containers of this type of glass usually available.

<sup>b</sup> Size indicates the overflow capacity of the container.

#### Arsenic

[Arsenic](#) (211) — Use as the Test Preparation 35 mL of the water from one Type I glass container or, in the case of smaller containers, 35 mL of the combined contents of several Type I glass containers, prepared as directed for Procedure under Water Attack at 121° or Surface Glass Test: the limit is 0.1 µg per g.

1 A suitable mortar and pestle is available (catalog No. H-17280) from Humboldt Manufacturing Co., 7300 West Agatite Avenue, Norridge, IL, 60706, [www.humboldtmfg.com](#)

2 A suitable nuclear-grade resin mixture of the strong acid cation exchanger in the hydrogen form and the strong base anion exchanger in the hydroxide form, with a one-to-one cation to anion equivalence ratio, is available from the Millipore Corp, 290 Concord Road Billerica, MA, 01821, [www.millipore.com](#); Barnstead International, 2555 Kerper Boulevard Dubuque, IA, 52004, [www.barnsteadthermolyne.com](#); GE Water, 4636 Somerton Road Trevose, PA, 19053, [www.gewater.com](#); Pall, 2200 Northern Boulevard East Hills, NY 11548, [www.pall.com](#); Whatman, 200 Park Avenue Florham Park, NJ, 07932, [www.whatman.com](#); Siemens Water Technologies, 14950 Heathrow Forest Pa, Houston, TX 77032, [www.usfilter.com](#)

General Chapter	<a href="#">Desmond G. Hunt, Ph.D.</a>	(PS05) Packaging and Storage 05

## INTRODUCTION

It is the purpose of this chapter to provide standards for plastic materials and components used to package medical articles (pharmaceuticals, biologics, dietary supplements, and devices). Definitions that apply to this chapter are provided in the Preservation, Packaging, Storage, and Labeling section of the General Notices and Requirements. Standards and tests for the functional properties of containers and their components are provided in general chapter [Containers—Performance Testing \(671\)](#).

In addition to the standards provided herein, the ingredients added to the polymers, and those used in the fabrication of the containers, must conform to the requirements in the applicable sections of the Code of Federal Regulations, Title 21, Indirect Food Additives, or have been evaluated by the FDA and determined to be acceptable substances for the listed use.

Plastic articles are identified and characterized by IR spectroscopy and differential scanning calorimetry. Standards are provided in this chapter for the identification and characterization of the different types of plastic, and the test procedures are provided at the end of the chapter. The degree of testing is based on whether or not the container has direct contact with the drug product, and the risk is based on the route of administration.

Plastics are composed of a mixture of homologous polymers, having a range of molecular weights. Plastics may contain other substances such as residues from the polymerization process, plasticizers, stabilizers, antioxidants, pigments, and lubricants. These materials meet the requirements for food contact as provided in the Code of Federal Regulations, Title 21. Factors such as plastic composition, processing and cleaning procedures, surface treatment, contacting media, inks, adhesives, absorption and permeability of preservatives, and conditions of storage may also affect the suitability of a plastic for a specific use. Extraction tests are designed to characterize the extracted components and identify possible migrants.

The degree or extent of testing for extractables of the component is dependent on the intended use and the degree of risk to adversely impact the efficacy of the compendial article (drug, biologic, dietary supplement, or device). Resin-specific extraction tests are provided in this chapter for polyethylene, polypropylene, polypropylene terephthalate, and polypropylene terephthalate G. Test all other plastics as directed under Physicochemical Tests in the section Test Methods. Conduct the Buffering Capacity test only when the containers are intended to hold a liquid product.

Plastic components used for products of high risk, such as those intended for inhalation, parenteral preparation, and ophthalmics are tested using the Biological Tests in the section Test Methods.

Plastic containers intended for packaging products prepared for parenteral use meet the requirements under Biological Tests and Physicochemical Tests in the section Test Methods. Standards are also provided for polyethylene containers used to package dry oral dosage forms that are not meant for constitution into solution.

## POLYETHYLENE CONTAINERS

## Scope

The standards and tests provided in this section characterize containers and components produced from either low-density polyethylene or high-density polyethylene of either homopolymer or copolymer resin. All polyethylene components are subject to testing by IR spectroscopy and differential scanning calorimetry. Where stability studies have been performed to establish the expiration date of a particular dosage form in the appropriate polyethylene container, then any other polyethylene container meeting these requirements may be similarly used to package such a dosage form, provided that the appropriate stability programs are expanded to include the alternative container, in order to ensure that the identity, strength, quality, and purity of the dosage form are maintained throughout the expiration period.

## Background

High-density and low-density polyethylene are long-chain polymers synthesized under controlled conditions of heat and pressure, with the aid of catalysts from not less than 85.0% ethylene and not less than 95.0% total olefins. Other olefin ingredients that are most frequently used are butene, hexene, and propylene. High-density polyethylene and low-density polyethylene both have an IR absorption spectrum that is distinctive for polyethylene, and each possesses characteristic thermal properties. High-density polyethylene has a density between 0.941 and 0.965 g per cm<sup>3</sup>. Low-density polyethylene has a density between 0.850 and 0.940 g per cm<sup>3</sup>. Other properties that may affect the suitability of polyethylene include modulus of elasticity, melt index, environmental stress crack resistance, and degree of crystallinity after molding.

## High-Density Polyethylene

Infrared Spectroscopy— Proceed as directed under Multiple Internal Reflectance in the section Test Methods. The corrected spectrum of the specimen exhibits major absorption bands only at the same wavelengths as the spectrum of [USP High-Density Polyethylene RS](#).

Differential Scanning Calorimetry— Proceed as directed under Thermal Analysis in the section Test Methods. The thermogram of the specimen is similar to the thermogram of [USP High-Density Polyethylene RS](#), similarly determined, and the temperature of the endotherm (melt) in the thermogram of the specimen does not differ from that of the USP Reference Standard by more than 6.0°.

Heavy Metals and Nonvolatile Residue— Prepare extracts of specimens for these tests as directed for under Physicochemical Tests in the section Test Methods, except Sample Preparation that for each 20.0 mL of Extracting Medium the portion shall be 60 cm<sup>2</sup>, regardless of thickness.

HEAVY METALS— Containers meet the requirements for Heavy Metals under Physicochemical Tests in the section Test Methods.

NONVOLATILE RESIDUE— Proceed as directed for Nonvolatile Residue under Physicochemical Tests, except that the Blank shall be the same solvent used in each of the following test conditions: the difference between the amounts obtained from the Sample Preparation and the Blank does not exceed 12.0 mg when water maintained at a temperature of 70° is used as the Extracting Medium; does not exceed 75.0 mg when alcohol maintained at a temperature of 70° is used as the Extracting Medium; and does not exceed 100.0 mg when hexanes maintained at a temperature of 50° is used as the Extracting Medium.

Components Used in Contact with Oral Liquids— Proceed as directed under Buffering Capacity under Physicochemical Tests in the section Test Methods.

## Low-Density Polyethylene

Infrared Spectroscopy— Proceed as directed under Multiple Internal Reflectance in the section Test Methods. The corrected spectrum of the specimen exhibits major absorption bands only at the same wavelengths as the spectrum of [USP Low-Density Polyethylene RS](#).

Differential Scanning Calorimetry— Proceed as directed under Thermal Analysis in the section Test Methods. The thermogram of the specimen is similar to the thermogram of [USP Low-Density Polyethylene RS](#), similarly determined, and the temperature of the endotherm (melt) in the thermogram of the specimen does not differ from that of the USP Reference Standard by more than 8.0°.

Heavy Metals and Nonvolatile Residue— Prepare extracts of specimens for these tests as directed for Sample Preparation under Physicochemical Tests in the section Test Methods, except that for each 20.0 mL of Extracting Medium the portion shall be 60 cm<sup>2</sup>, regardless of thickness.

HEAVY METALS— Containers meet the requirements for Heavy Metals under Physicochemical Tests in the section Test Methods.

NONVOLATILE RESIDUE— Proceed as directed for Nonvolatile Residue under Physicochemical Tests in the section Test Methods, except that the Blank shall be the same solvent used in each of the following test conditions: the difference between the amounts obtained from the Sample Preparation and the Blank does not exceed 12.0 mg when water maintained at a temperature of 70° is used as the Extracting Medium; does not exceed 75.0 mg when alcohol maintained at a temperature of 70° is used as the Extracting Medium; and does not

exceed 350.0 mg when hexanes maintained at a temperature of 50° is used as the Extracting Medium.

Components Used in Contact with Oral Liquids— Proceed as directed under Buffering Capacity under Physicochemical Tests in the section Test Methods.

## POLYPROPYLENE CONTAINERS

### Scope

The standards and tests provided in this section characterize polypropylene containers, produced from either homopolymers or copolymers, that are interchangeably suitable for packaging dry solid and liquid oral dosage forms. Where suitable stability studies have been performed to establish the expiration date of a particular dosage form in the appropriate polypropylene container, then any other polypropylene container meeting these requirements may be similarly used to package such a dosage form, provided that the appropriate stability programs are expanded to include the alternative container, in order to ensure that the identity, strength, quality, and purity of the dosage form are maintained throughout the expiration period.

### Background

Propylene polymers are long-chain polymers synthesized from propylene or propylene and other olefins under controlled conditions of heat and pressure, with the aid of catalysts.

Examples of other olefins most commonly used include ethylene and butene. The propylene polymers, the ingredients used to manufacture the propylene polymers, and the ingredients used in the fabrication of the containers conform to the applicable sections of the Code of Federal Regulations, Title 21.

Factors such as plastic composition, processing and cleaning procedures, contacting media, inks, adhesives, absorption, adsorption and permeability of preservatives, and conditions of storage may also affect the suitability of a plastic for a specific use. The suitability of a specific polypropylene must be established by appropriate testing.

Polypropylene has a distinctive IR spectrum and possesses characteristic thermal properties. It has a density between 0.880 and 0.913 g per cm<sup>3</sup>. The permeation properties of molded polypropylene containers may be altered when reground polymer is incorporated, depending on the proportion of reground material in the final product. Other properties that may affect the suitability of polypropylene used in containers for packaging drugs are the following: oxygen and moisture permeability, modulus of elasticity, melt flow index, environmental stress crack resistance, and degree of crystallinity after molding. The requirements in this section are to be met when dry solid and liquid oral dosage forms are to be packaged in a container defined by this section.

Infrared Spectroscopy— Proceed as directed under Multiple Internal Reflectance in the section Test Methods. The corrected spectrum of the specimen exhibits major absorption bands only at the same wavelengths as the spectrum of the respective [USP Homopolymer Polypropylene RS](#) or USP Copolymer Polypropylene RS, similarly determined.

Differential Scanning Calorimetry— Proceed as directed under Thermal Analysis in the section Test Methods. The temperature of the endotherm (melt) in the thermogram does not differ from that of the USP Reference Standard for homopolymers by more than 6.0°. The temperature of the endotherm obtained from the thermogram of the copolymer polypropylene specimen does not differ from that of the copolymer polypropylene standard by more than 12.0°.

Heavy Metals and Nonvolatile Residue— Prepare extracts of specimens for these tests as directed for Sample Preparation under Physicochemical Tests in the section Test Methods, except that for each 20 mL of Extracting Medium the portion shall be 60 cm<sup>2</sup>, regardless of thickness.

HEAVY METALS— Containers meet the requirements for Heavy Metals under Physicochemical Tests in the section Test Methods.

NONVOLATILE RESIDUE— Proceed as directed for Nonvolatile Residue under Physicochemical Tests in the section Test Methods, except that the Blank shall be the same solvent used in each of the following test conditions: the difference between the amounts obtained from the Sample Preparation and the Blank does not exceed 10.0 mg when water maintained at a temperature of 70° is used as the Extracting Medium; does not exceed 60.0 mg when alcohol maintained at a temperature of 70° is used as the Extracting Medium; and does not exceed 225.0 mg when hexanes maintained at a temperature of 50° is used as the Extracting Medium. Containers meet these requirements for Nonvolatile Residue for all of the above extracting media. [note—Hexanes and alcohol are flammable. When evaporating these solvents, use a current of air with the water bath; when drying the residue, use an explosion-proof oven.]

Components Used in Contact with Oral Liquids— Proceed as directed in Buffering Capacity under Physicochemical Tests in the section Test Methods.

## POLYETHYLENE TEREPHTHALATE BOTTLES AND POLYETHYLENE TEREPHTHALATE G CONTAINERS

### Scope

The standards and tests provided in this section characterize polyethylene terephthalate (PET) and polyethylene terephthalate G (PETG) bottles that are interchangeably suitable for packaging liquid oral dosage forms. Where stability studies have been performed to establish the expiration date of a particular liquid oral dosage form in a bottle meeting the requirements set forth herein for either PET or PETG bottles, any other PET or PETG bottle meeting these requirements may be similarly used to package such a dosage form, provided that the appropriate stability programs are expanded to include the alternative bottle in order to ensure that the identity, strength, quality, and purity of the dosage form are maintained throughout the expiration period. The suitability of a specific PET or PETG bottle for use in the dispensing of a particular pharmaceutical liquid oral dosage form must be established by appropriate testing.

### Background

PET resins are long-chain crystalline polymers prepared by the condensation of ethylene glycol with dimethyl terephthalate or terephthalic acid. PET copolymer resins are prepared in a similar way, except that they may also contain a small amount of either isophthalic acid (not more than 3 mole percent) or 1,4-cyclohexanedimethanol (not more than 5 mole percent). Polymerization is conducted under controlled conditions of heat and vacuum, with the aid of catalysts and stabilizers.

PET copolymer resins have physical and spectral properties similar to PET and for practical purposes are treated as PET. The tests and specifications provided in this section to characterize PET resins and bottles apply also to PET copolymer resins and to bottles fabricated from them.

PET and PET copolymer resins generally exhibit a large degree of order in their molecular structure. As a result, they exhibit characteristic composition-dependent thermal behavior, including a glass transition temperature of about 76° and a melting temperature of about 250°. These resins have a distinctive IR absorption spectrum that allows them to be distinguished from other plastic materials (e.g., polycarbonate, polystyrene, polyethylene, and PETG resins). PET and PET copolymer resins have a density between 1.3 and 1.4 g per cm<sup>3</sup> and a minimum intrinsic viscosity of 0.7 dL per g, which corresponds to a number average molecular weight of about 23,000 Da.

PETG resins are high molecular weight polymers prepared by the condensation of ethylene glycol with dimethyl terephthalate or terephthalic acid and 15 to 34 mole percent of 1,4-cyclohexanedimethanol. PETG resins are clear, amorphous polymers, having a glass transition temperature of about 81° and no crystalline melting point, as determined by differential scanning calorimetry. PETG resins have a distinctive IR absorption spectrum that allows them to be distinguished from other plastic materials, including PET. PETG resins have a density of approximately 1.27 g per cm<sup>3</sup> and a minimum intrinsic viscosity of 0.65 dL per g, which corresponds to a number average molecular weight of about 16,000 Da.

PET and PETG resins, and other ingredients used in the fabrication of these bottles, conform to the requirements in the applicable sections of the Code of Federal Regulations, Title 21, regarding use in contact with food and alcoholic beverages. PET and PETG resins do not contain any plasticizers, processing aids, or antioxidants. Colorants, if used in the manufacture of PET and PETG bottles, do not migrate into the contained liquid.

Infrared Spectroscopy— Proceed as directed under Multiple Internal Reflectance in the section Test Methods. The corrected spectrum of the specimen exhibits major absorption bands only at the same wavelengths as the spectrum of [USP Polyethylene Terephthalate RS](#), or [USP Polyethylene Terephthalate G RS](#), similarly determined.

Differential Scanning Calorimetry— Proceed as directed under Thermal Analysis in the section Test Methods. For polyethylene terephthalate, the thermogram of the specimen is similar to the thermogram of [USP Polyethylene Terephthalate RS](#), similarly determined: the melting point (T<sub>m</sub>) of the specimen does not differ from that of the USP Reference Standard by more than 9.0°, and the glass transition temperature (T<sub>g</sub>) of the specimen does not differ from that of the USP Reference Standard by more than 4.0°. For polyethylene terephthalate G, the thermogram of the specimen is similar to the thermogram of USP Polyethylene Terephthalate G RS, similarly determined: the glass transition temperature (T<sub>g</sub>) of

the specimen does not differ from that of the USP Reference Standard by more than 6.0°.

Colorant Extraction— Select three test bottles. Cut a relatively flat portion from the side wall of one bottle, and trim it as necessary to fit the sample holder of the spectrophotometer.

Obtain the visible spectrum of the side wall by scanning the portion of the visible spectrum from 350 to 700 nm. Determine, to the nearest 2 nm, the wavelength of maximum absorbance. Fill the remaining two test bottles, using 50% alcohol for PET bottles and 25% alcohol for PETG bottles. Fit the bottles with impervious seals, such as aluminum foil, and apply closures. Fill a glass bottle having the same capacity as that of the test bottles with the corresponding solvent, fit the bottle with an impervious seal, such as aluminum foil, and apply a closure. Incubate the test bottles and the glass bottle at 49° for 10 days. Remove the bottles, and allow them to equilibrate to room temperature. Concomitantly determine the absorbances of the test solutions in 5-cm cells at the wavelength of maximum absorbance (see [Spectrophotometry and Light-Scattering \(851\)](#)), using the corresponding solvent from the glass bottle as the blank. The absorbance values so obtained are less than 0.01 for both test solutions.

#### Heavy Metals, Total Terephthaloyl Moieties, and Ethylene Glycol—

##### EXTRACTING MEDIA—

[Purified Water](#)— (see monograph).

50 Percent Alcohol— Dilute 125 mL of alcohol with water to 238 mL, and mix.

25 Percent Alcohol— Dilute 125 mL of 50 Percent Alcohol with water to 250 mL, and mix.

n-Heptane.

GENERAL PROCEDURE— [note—Use an Extracting Medium of 50 Percent Alcohol for PET bottles and 25 Percent Alcohol for PETG bottles.] For each Extracting Medium, fill a sufficient number of test bottles to 90% of their nominal capacity to obtain not less than 30 mL. Fill a corresponding number of glass bottles with Purified Water, a corresponding number of glass bottles with 50 Percent Alcohol or 25 Percent Alcohol, and a corresponding number of glass bottles with n-Heptane for use as Extracting Media blanks. Fit the bottles with impervious seals, such as aluminum foil, and apply closures. Incubate the test bottles and the glass bottles at 49° for 10 days. Remove the test bottles with the Extracting Media samples and the glass bottles with the Extracting Media blanks, and store them at room temperature. Do not transfer the Extracting Media samples to alternative storage vessels.

HEAVY METALS— Pipet 20 mL of the Purified Water extract of the test bottles, filtered if necessary, into one of two matched 50-mL color-comparison tubes, and retain the remaining Purified Water extract in the test bottles for use in the test for Ethylene Glycol. Adjust the extract with 1 N acetic acid or 6 N ammonium hydroxide to a pH between 3.0 and 4.0, using short-range pH paper as an external indicator. Dilute with water to about 35 mL, and mix.

Into the second color-comparison tube, pipet 2 mL of freshly prepared (on day of use) Standard Lead Solution (see [Heavy Metals \(231\)](#)), and add 20 mL of Purified Water. Adjust with 1 N acetic acid or 6 N ammonium hydroxide to a pH between 3.0 and 4.0, using short-range pH paper as an external indicator. Dilute with water to about 35 mL, and mix.

To each tube add 1.2 mL of thioacetamide–glycerin base TS and 2 mL of pH 3.5 Acetate Buffer (see [Heavy Metals \(231\)](#)), dilute with water to 50 mL, and mix: any color produced within 10 minutes in the tube containing the Purified Water extract of the test bottles does not exceed that in the tube containing the Standard Lead Solution, both tubes being viewed downward over a white surface (1 ppm in extract).

TOTAL TEREPHTHALOYL MOIETIES— Determine the absorbance of the 50 Percent Alcohol or 25 Percent Alcohol extract in a 1-cm cell at the wavelength of maximum absorbance at about 244 nm (see [Spectrophotometry and Light-Scattering \(851\)](#)), using as the blank the corresponding Extracting Medium blank: the absorbance of the extract does not exceed 0.150, corresponding to not more than 1 ppm of total terephthaloyl moieties.

Determine the absorbance of the n-Heptane extract in a 1-cm cell at the wavelength of maximum absorbance at about 240 nm (see [Spectrophotometry and Light-Scattering \(851\)](#)), using as the blank the n-Heptane Extracting Medium: the absorbance of the extract does not exceed 0.150, corresponding to not more than 1 ppm of total terephthaloyl moieties.

##### ETHYLENE GLYCOL—

Periodic Acid Solution— Dissolve 125 mg of periodic acid in 10 mL of water.

Dilute Sulfuric Acid— To 50 mL of water add slowly and with constant stirring 50 mL of sulfuric acid, and allow to cool to room temperature.

Sodium Bisulfite Solution— Dissolve 0.1 g of sodium bisulfite in 10 mL of water. Use this solution within 7 days.

Disodium Chromotropate Solution— Dissolve 100 mg of disodium chromotropate in 100 mL of sulfuric acid. Protect this solution from light, and use within 7 days.

Standard Solution— Dissolve an accurately weighed quantity of ethylene glycol in water, and dilute quantitatively, and stepwise if necessary, to obtain a solution having a known concentration of about 1 µg per mL.

Test Solution— Use the Purified Water extract.

Procedure— Transfer 1.0 mL of the Standard Solution to a 10-mL volumetric flask. Transfer 1.0 mL of the Test Solution to a second 10-mL volumetric flask. Transfer 1.0 mL of the Purified Water Extracting Medium to a third 10-mL volumetric flask. To each of the three flasks, add 100 µL of Periodic Acid Solution, swirl to mix, and allow to stand for 60 minutes. Add 1.0 mL of Sodium Bisulfite Solution to each flask, and mix. Add 100 µL of Disodium Chromotropate Solution to each flask, and mix. [note—All solutions should be analyzed within 1 hour after addition of the Disodium Chromotropate Solution.] Cautiously add 6 mL of sulfuric acid to each flask, mix, and allow the solutions to cool to room temperature. [Caution—Dilution of sulfuric acid produces substantial heat and can cause the solution to boil. Perform this addition carefully. Sulfur dioxide gas will be evolved. Use of a fume hood is recommended.] Dilute each solution with Dilute Sulfuric Acid to volume, and mix. Concomitantly determine the absorbances of the solutions from the Standard Solution and the Test

Solution in 1-cm cells at the wavelength of maximum absorbance at about 575 nm (see [Spectrophotometry and Light-Scattering \(851\)](#)), using as the blank the solution from the Purified Water Extracting Medium: the absorbance of the solution from the Test Solution does not exceed that of the solution from the Standard Solution, corresponding to not more than 1 ppm of ethylene glycol.

## TEST METHODS

### Multiple Internal Reflectance

Apparatus— Use an IR spectrophotometer capable of correcting for the blank spectrum and equipped with a multiple internal reflectance accessory and a KRS-5 internal reflection plate.<sup>1</sup> A KRS-5 crystal 2-mm thick having an angle of incidence of 45° provides a sufficient number of reflections.

Specimen Preparation— Cut two flat sections representative of the average wall thickness of the container, and trim them as necessary to obtain segments that are convenient for mounting in the multiple internal reflectance accessory. Taking care to avoid scratching the surfaces, wipe the specimens with dry paper or, if necessary, clean them with a soft cloth dampened with methanol, and permit them to dry. Securely mount the specimens on both sides of the KRS-5 internal reflection plate, ensuring adequate surface contact. Prior to mounting the specimens on the plate, they may be compressed to thin uniform films by exposing them to temperatures of about 177° under high pressures (15,000 psi or more).

General Procedure— Place the mounted specimen sections within the multiple internal reflectance accessory, and place the assembly in the specimen beam of the IR spectrophotometer. Adjust the specimen position and mirrors within the accessory to permit maximum light transmission of the unattenuated reference beam. (For a double-beam instrument, upon completing the adjustments in the accessory, attenuate the reference beam to permit full-scale deflection during the scanning of the specimen.) Determine the IR spectrum from 3500 to 600 cm<sup>-1</sup> for polyethylene and polypropylene and from 4000 to 400 cm<sup>-1</sup> for PET and PETG.

### Thermal Analysis

General Procedure— Cut a section weighing about 12 mg, and place it in the test specimen pan. [note—Intimate contact between the pan and the thermocouple is essential for reproducible results.] Determine the thermogram under nitrogen, using the heating and cooling conditions as specified for the resin type and using equipment capable of performing the determinations as specified under [Thermal Analysis \(891\)](#).

For Polyethylene— Determine the thermogram under nitrogen at temperatures between 40° and 200° at a heating rate between 2° and 10° per minute followed by cooling at a rate

between 2° and 10° per minute to 40°.

For Polypropylene— Determine the thermogram under nitrogen at temperatures ranging from ambient to 30° above the melting point. Maintain the temperature for 10 minutes, then cool to 50° below the peak crystallization temperature at a rate of 10° to 20° per minute.

For Polyethylene Terephthalate— Heat the specimen from room temperature to 280° at a heating rate of about 20° per minute. Hold the specimen at 280° for 1 minute. Quickly cool the specimen to room temperature, and reheat it to 280° at a heating rate of about 5° per minute.

For Polyethylene Terephthalate G— Heat the specimen from room temperature to 120° at a heating rate of about 20° per minute. Hold the specimen at 120° for 1 minute. Quickly cool the specimen to room temperature, and reheat it to 120° at a heating rate of about 10° per minute.

#### Biological Tests

The in vitro biological tests are performed according to the procedures set forth under [Biological Reactivity Test, In Vitro](#) (87). Components that meet the requirements of the in vitro tests are not required to undergo further testing. No plastic class designation is assigned to these materials. Materials that do not meet the requirements of the in vitro tests are not suitable for containers for drug products.

If a plastic class designation is needed for plastics and other polymers that meet the requirements under [Biological Reactivity Test, In Vitro](#) (87), perform the appropriate in vivo test specified for Classification of Plastics under [Biological Reactivity Test, In Vivo](#) (88).

#### Physicochemical Tests

The following tests, designed to determine physical and chemical properties of plastics and their extracts, are based on the extraction of the plastic material, and it is essential that the designated amount of the plastic be used. Also, the specified surface area must be available for extraction at the designated temperature.

#### Testing Parameters—

Extracting Medium— Unless otherwise directed in a specific test below, use [Purified Water](#) (see monograph) as the Extracting Medium, maintained at a temperature of 70° during the extraction of the Sample Preparation.

Blank— Use [Purified Water](#) where a blank is specified in the tests that follow.

Apparatus— Use a water bath and the Extraction Containers as described under [Biological Reactivity Tests, In Vivo](#) (88). Proceed as directed in the first paragraph of Preparation of Apparatus under [Biological Reactivity Tests, In Vivo](#) (88). [note—The containers and equipment need not be sterile.]

Sample Preparation— From a homogeneous plastic specimen, use a portion, for each 20.0 mL of Extracting Medium, equivalent to 120 cm<sup>2</sup> total surface area (both sides combined), and subdivide into strips approximately 3 mm in width and as near to 5 cm in length as is practical. Transfer the subdivided sample to a glass-stoppered, 250-mL graduated cylinder of Type I glass, and add about 150 mL of Purified Water. Agitate for about 30 seconds, drain off and discard the liquid, and repeat with a second washing.

Sample Preparation Extract— Transfer the prepared Sample Preparation to a suitable extraction flask, and add the required amount of Extracting Medium. Extract by heating in a water bath at the temperature specified for the Extracting Medium for 24 hours. Cool, but not below 20°. Pipet 20 mL of the prepared extract into a suitable container. [note—Use this portion in the test for Buffering Capacity.] Immediately decant the remaining extract into a suitably cleansed container, and seal.

Nonvolatile Residue— Transfer, in suitable portions, 50.0 mL of the Sample Preparation Extract to a suitable, tared crucible (preferably a fused-silica crucible that has been acid-cleaned), and evaporate the volatile matter on a steam bath. Similarly evaporate 50.0 mL of the Blank in a second crucible. [note—If an oily residue is expected, inspect the crucible repeatedly during the evaporation and drying period, and reduce the amount of heat if the oil tends to creep along the walls of the crucible.] Dry at 105° for 1 hour: the difference between the amounts obtained from the Sample Preparation Extract and the Blank does not exceed 15 mg.

[Residue on Ignition](#) (281)— [note—It is not necessary to perform this test when the Nonvolatile Residue test result does not exceed 5 mg.] Proceed with the residues obtained from the Sample Preparation Extract and from the Blank in the test for Nonvolatile Residue above, using, if necessary, additional sulfuric acid but adding the same amount of sulfuric acid to each crucible: the difference between the amounts of residue on ignition obtained from the Sample Preparation Extract and the Blank does not exceed 5 mg.

Heavy Metals— Pipet 20 mL of the Sample Preparation Extract, filtered if necessary, into one of two matched 50-mL color-comparison tubes. Adjust with 1 N acetic acid or 6 N ammonium hydroxide to a pH between 3.0 and 4.0, using short-range pH paper as an external indicator, dilute with water to about 35 mL, and mix.

Into the second color-comparison tube pipet 2 mL of Standard Lead Solution (see [Heavy Metals](#) (231)), and add 20 mL of the Blank. Adjust with 1 N acetic acid or 6 N ammonium hydroxide to a pH between 3.0 and 4.0, using short-range pH paper as an external indicator, dilute with water to about 35 mL, and mix. To each tube add 1.2 mL of thioacetamide-glycerin base TS and 2 mL of pH 3.5 Acetate Buffer (see [Heavy Metals](#) (231)), dilute with water to 50 mL, and mix: any brown color produced within 10 minutes in the tube containing the Sample Preparation Extract does not exceed that in the tube containing the Standard Lead Solution, both tubes being viewed downward over a white surface (1 ppm in extract).

Buffering Capacity— Titrate the previously collected 20-mL portion of the Sample Preparation Extract potentiometrically to a pH of 7.0, using either 0.010 N hydrochloric acid or 0.010 N sodium hydroxide, as required. Treat a 20.0-mL portion of the Blank similarly: if the same titrant was required for both the Sample Preparation Extract and the Blank, the difference between the two volumes is not greater than 10.0 mL; and if acid was required for either the Sample Preparation Extract or the Blank and alkali for the other, the total of the two volumes required is not greater than 10.0 mL.

1 The multiple internal reflectance accessory and KRS-5 plate are available from several sources, including Beckman Instruments, Inc., 2500 Harbor Blvd., Fullerton, CA 92634, and from Perkin Elmer Corp., Main Ave., Norwalk, CT 06856.

Auxiliary Information— Please [check for your question in the FAQs](#) before contacting USP.

#### 671 CONTAINERS—PERFORMANCE TESTING

It is the purpose of this chapter to provide standards for the functional properties of plastic containers and their components used to package regulated articles (pharmaceuticals, biologics, dietary supplements, and devices). Definitions that apply to this chapter are provided in the Preservation, Packaging, Storage, and Labeling section of the General Notices and Requirements. The tests that follow are provided to determine the moisture permeability and light transmission of plastic containers utilized for regulated articles. The section Multiple-Unit Containers for Capsules and Tablets applies to multiple-unit containers. The section Single-Unit Containers and Unit-Dose Containers for Capsules and Tablets applies to single-unit and unit-dose containers. The section Multiple-Unit Containers for Capsules and Tablets (Without Closure) applies to polyethylene and polypropylene containers that have no closures. The section Multiple-Unit and Single-Unit Containers for Liquids applies to multiple-unit and single-unit containers.

A container intended to provide protection from light or offered as a light-resistant container meets the requirements for Light Transmission, where such protection or resistance is by virtue of the specific properties of the material of which the container is composed, including any coating applied thereto. A clear and colorless or a translucent container that is made

...resistant by means of an opaque enclosure (see General Notices and Requirements) is exempt from the requirements for Light Transmission. As used herein, the term "container" refers to the entire system comprising, usually, the container itself, the liner (if used), the closure in the case of multiple-unit containers, and the lidding and blister in the case of unit-dose containers.

#### MULTIPLE-UNIT CONTAINERS FOR CAPSULES AND TABLETS

Desiccant— Place a quantity of 4- to 8-mesh, anhydrous calcium chloride<sup>1</sup> in a shallow container, taking care to exclude any fine powder, then dry at 110° for 1 hour, and cool in a desiccator.

Procedure— Select 12 containers of a uniform size and type, clean the sealing surfaces with a lint-free cloth, and close and open each container 30 times. Apply the closure firmly and uniformly each time the container is closed. Close screw-capped containers with a torque that is within the range of tightness specified in the accompanying table. Add Desiccant to 10 of the containers, designated test containers, filling each to within 13 mm of the closure if the container volume is 20 mL or more, or filling each to two-thirds of capacity if the container volume is less than 20 mL. If the interior of the container is more than 63 mm in depth, an inert filler or spacer may be placed in the bottom to minimize the total weight of the container and Desiccant; the layer of Desiccant in such a container shall be not less than 5 cm in depth. Close each immediately after adding Desiccant, applying the torque designated in the accompanying table when closing screw-capped containers. To each of the remaining 2 containers, designated controls, add a sufficient number of glass beads to attain a weight approximately equal to that of each of the test containers, and close, applying the torque designated in the accompanying table when closing screw-capped containers. Record the weight of the individual containers so prepared to the nearest 0.1 mg if the container volume is less than 20 mL; to the nearest mg if the container volume is 20 mL or more but less than 200 mL; or to the nearest centigram (10 mg) if the container volume is 200 mL or more; and store at 75 ± 3% relative humidity and a temperature of 23 ± 2°. [note—A saturated system of 35 g of sodium chloride with each 100 mL of water placed in the bottom of a desiccator maintains the specified humidity. Other methods may be employed to maintain these conditions.] After 336 ± 1 hours (14 days), record the weight of the individual containers in the same manner. Completely fill 5 empty containers of the same size and type as the containers under test with water or a noncompressible, free-flowing solid such as well-tamped fine glass beads, to the level indicated by the closure surface when in place. Transfer the contents of each to a graduated cylinder, and determine the average container volume, in mL. Calculate the rate of moisture permeability, in mg per day per L, by the formula:

$$(1000 / 14V)[(TF - TI) - (CF - CI)]$$

in which V is the volume, in mL, of the container, (TF - TI) is the difference, in mg, between the final and initial weights of each test container, and (CF - CI) is the difference, in mg, between the average final and average initial weights of the 2 controls. For containers used for drugs being dispensed on prescription, the containers so tested are tight containers if not more than one of the 10 test containers exceeds 100 mg per day per L in moisture permeability, and none exceeds 200 mg per day per L.

For containers used for drugs being dispensed on prescription, the containers are well-closed containers if not more than one of the 10 test containers exceeds 2000 mg per day per L in moisture permeability, and none exceeds 3000 mg per day per L.

#### Torque Applicable to Screw-Type Container

Closure Diameter <sup>a</sup> (mm)	Suggested Tightness Range with Manually Applied Torque, <sup>b</sup> (inch-pounds)
8	5
10	6
13	8
15	5–9
18	7–10
20	8–12
22	9–14
24	10–18
28	12–21
30	13–23
33	15–25
38	17–26
43	17–27
48	19–30
53	21–36
58	23–40
63	25–43
66	26–45
70	28–50
83	32–65
86	40–65
89	40–70
100	45–70
110	45–70
120	55–95
132	60–95

a The torque designated for the next larger closure diameter is to be applied in testing containers having a closure diameter intermediate to the diameters listed.

b A suitable apparatus is available from Owens-Illinois, Toledo, OH 43666. (Model 25 torque tester is used for testing between 0 and 25; Model 50 for testing between 0 and 50; and Model 100 for testing between 0 and 100 inch-pounds of torque.) The torque values refer to application, not removal, of the closure. For further detail regarding instructions, reference may be made to "Standard Test Method for Application and Removal Torque of Threaded or Lug-Style Closures" ASTM Method D3198-97, published by the American Society for Testing and Materials, 100 Barr Harbor Drive, P. O. Box C700, West Conshohocken, PA 19428-2959.

#### MULTIPLE-UNIT CONTAINERS FOR CAPSULES AND TABLETS

##### (Without Closure)

Polyethylene Container— Fit the containers with impervious seals obtained by heat-sealing the bottles with an aluminum foil–polyethylene laminate or other suitable seal.<sup>2</sup> Test the containers as specified under Multiple-Unit Containers for Capsules and Tablets: the high-density polyethylene containers so tested meet the requirements if the moisture permeability exceeds 10 mg per day per L in not more than 1 of the 10 test containers and exceeds 25 mg per day per L in none of them. The low-density polyethylene containers so tested meet the requirements if the moisture permeability exceeds 20 mg per day per L in not more than 1 of the 10 test containers and exceeds 30 mg per day per L in none of them.

—Polypropylene Containers— Fit the containers with impervious seals obtained by heat-sealing the bottles with an aluminum foil-polyethylene laminate or other suitable seal. Test the containers as described under Multiple-Unit Containers for Capsules and Tablets. The containers meet the requirements if the moisture permeability exceeds 15 mg per day per L in not more than 1 of the 10 test containers and exceeds 25 mg per day per L in none of them.

#### SINGLE-UNIT CONTAINERS AND UNIT-DOSE CONTAINERS FOR CAPSULES AND TABLETS

To permit an informed judgment regarding the suitability of the packaging for a particular type of product, the following procedure and classification scheme are provided for evaluating the moisture-permeation characteristics of single-unit and unit-dose containers. Inasmuch as equipment and operator performance may affect the moisture permeation of a container formed or closed, the moisture-permeation characteristics of the packaging system being utilized shall be determined.

Desiccant— Dry suitable desiccant pellets<sup>3</sup> at 110° for 1 hour prior to use. Use pellets weighing approximately 400 mg each and having a diameter of approximately 8 mm. [note—If necessary due to limited unit-dose container size, pellets weighing less than 400 mg each and having a diameter of less than 8 mm may be used.]

##### Procedure—

Method I— Seal not fewer than 10 unit-dose containers with 1 pellet in each, and seal 10 additional, empty unit-dose containers to provide the controls, using finger cots or padded forceps to handle the sealed containers. Number the containers, and record the individual weights<sup>4</sup> to the nearest mg. Weigh the controls as a unit, and divide the total weight by the number of controls to obtain the average. Store all of the containers at 75 ± 3% relative humidity and at a temperature of 23 ± 2°. [note—A saturated system of 35 g of sodium chloride with each 100 mL of water placed in the bottom of a desiccator maintains the specified humidity. Other methods may be employed to maintain these conditions.] After a 24-hour interval, and at each multiple thereof (see Results), remove the containers from the chamber, and allow them to equilibrate for 15 to 60 minutes in the weighing area. Again record the weight of the individual containers and the combined controls in the same manner. [note—If any indicating pellets turn pink during this procedure, or if the pellet weight increase exceeds 10%, terminate the test, and regard only earlier determinations as valid.] Return the containers to the humidity chamber. Calculate the rate of moisture permeation, in mg per day, of each container taken by the formula:

$$(1 / N)[(WF - WI) - (CF - CI)]$$

in which N is the number of days expired in the test period (beginning after the initial 24-hour equilibration period); (WF - WI) is the difference, in mg, between the final and initial weights of each test container; and (CF - CI) is the difference, in mg, between the average final and average initial weights of the controls, the data being calculated to two significant figures. [note—Where the permeations measured are less than 5 mg per day, and where the controls are observed to reach equilibrium within 7 days, the individual permeations may be determined more accurately by using the 7-day test container and control container weights as WI and CI, respectively, in the calculation. In this case, a suitable test interval for Class A (see Results) would be not less than 28 days following the initial 7-day equilibration period (a total of 35 days).]

Method II— Use this procedure for packs (e.g., punch-out cards) that incorporate a number of separately sealed unit-dose containers or blisters. Seal a sufficient number of packs, such that not fewer than 4 packs and a total of not fewer than 10 unit-dose containers or blisters filled with 1 pellet in each unit are tested. Seal a corresponding number of empty packs, each pack containing the same number of unit-dose containers or blisters as used in the test packs, to provide the controls. Store all of the containers at 75 ± 3% relative humidity and at a temperature of 23 ± 2°. [note—A saturated system of 35 g of sodium chloride with each 100 mL of water placed in the bottom of a desiccator maintains the specified humidity. Other methods may be employed to maintain these conditions.] After 24 hours, and at each multiple thereof (see Results), remove the packs from the chamber, and allow them to equilibrate for about 45 minutes. Record the weights of the individual packs, and return them to the chamber. Weigh the control packs as a unit, and divide the total weight by the number of control packs to obtain the average empty pack weight. [note—If any indicating pellets turn pink during the procedure, or if the average pellet weight increase in any pack exceeds 10%, terminate the test, and regard only earlier determinations as valid.] Calculate the average rate of moisture permeation, in mg per day, for each unit-dose container or blister in each pack taken by the formula:

$$(1 / NX)[(WF - WI) - (CF - CI)]$$

in which N is the number of days expired in the test period (beginning after the initial 24-hour equilibration period); X is the number of separately sealed units per pack; (WF - WI) is the difference, in mg, between the final and initial weights of each test pack; and (CF - CI) is the difference, in mg, between the average final and average initial weights of the control packs, the rates being calculated to two significant figures.

Results— The individual unit-dose containers as tested in Method I are designated Class A if not more than 1 of 10 containers tested exceeds 0.5 mg per day in moisture permeation rate and none exceeds 1 mg per day; they are designated Class B if not more than 1 of 10 containers tested exceeds 5 mg per day and none exceeds 10 mg per day; they are designated Class C if not more than 1 of 10 containers tested exceeds 20 mg per day and none exceeds 40 mg per day; and they are designated Class D if the containers tested meet none of the moisture permeation rate requirements.

The packs as tested in Method II are designated Class A if no pack tested exceeds 0.5 mg per day in average blister moisture permeation rate; they are designated Class B if no pack tested exceeds 5 mg per day in average blister moisture permeation rate; they are designated Class C if no pack tested exceeds 20 mg per day in average blister moisture permeation rate; and they are designated Class D if the packs tested meet none of the above average blister moisture permeation rate requirements.

With the use of the Desiccant described herein, as stated for Method I and Method II, after every 24 hours, the test and control containers or packs are weighed; and suitable test intervals for the final weighings, WF and CF, are as follows: 24 hours for Class D; 48 hours for Class C; 7 days for Class B; and not less than 28 days for Class A.

#### MULTIPLE-UNIT CONTAINERS AND UNIT-DOSE CONTAINERS FOR LIQUIDS

The standards and tests provided in this section measure the functional and performance characteristics of plastic containers used to package aqueous products by measuring the liquid water weight loss as a percent of the contents. This test can also be used to demonstrate performance or functional comparability. [note—Throughout the following procedure, determine the weights of individual container-closure systems (bottle, innerseal if used, and closure) both as tare weights and fill weights, to the nearest 0.1 mg if the bottle overflow capacity is less than 200 mL; to the nearest mg if the bottle overflow capacity is 200 mL or more but less than 1000 mL; or to the nearest centigram (10 mg) if the bottle overflow capacity is 1000 mL or more.]

Procedure for Testing Unopened Market Containers (cap liner [if applicable], innerseal, and cap)— Select 10 bottles of a uniform size and type, and clean the sealing surfaces with a lint-free cloth. Fit each bottle with a closure liner (if applicable) and closure. Number each container closure system, and record the tare weight.

Remove the closures and, using a pipette, fill the bottles with water to the overflow capacity. Fit the bottles with seals and apply the closures. If using screw closures, apply a torque that is within the range specified in [Table 1](#), and store the sealed containers at a temperature of 25 ± 2° and a relative humidity of 50 ± 2%. After 168 ± 1 hours (7 days), record the weight of the individual containers. Return the containers to storage for another 168 ± 1 hours. After the second 168 ± 1 hours, remove the containers, record the weights of each of the individual container systems, and calculate the water vapor permeation rate, in percent water weight loss, for each bottle taken by the formula:

$$(W7 - W14)365 \times 100/(W7 - WT)7 = \text{Percent per year}$$

in which W7 is the weight, in mg, of the container at 7 days; W14 is the weight, in mg, of the container at 14 days; WT is the tare weight in g; and 7 is the test time, in days, after the 7-day equilibration period. The containers so tested meet the requirements and are tight containers if the percentage of water weight loss exceeds 2.5% per year in not more than 1 of the 10 test containers and exceeds 5.0% per year in none of them.

Unit-dose containers for liquids meet the requirement of a tight container if the average water weight loss is less than or equal to 2.5% (w/w) loss per year (5% at the end of 2 years).

Procedure for Testing Multiple-Unit Containers Under Conditions of Use— Select 10 bottles of a uniform size and type. If an innerseal is used, carefully open the individual containers and remove the innerseal from each container. Fit each bottle with a closure liner (if applicable) and closure. Number each container-closure system, and record the tare weight. Open and close the containers 30 times being careful not to lose liquid in the process. Close screw-capped bottles with a torque that is within the range of tightness provided in [Table 1](#), and

store the sealed containers at a temperature of 25 ± 2° and a relative humidity of 50 ± 2%. After 168 ± 1 hours (7 days), record the weight of the individual containers. Return the containers to storage for another 168 ± 1 hours. After the second 168 ± 1 hours, remove the containers, record the weights of each of the individual container systems, and calculate

the water vapor permeation rate, in percent water weight loss, for each bottle taken by the formula:

$$(W7 - W14)365 \times 100 / (W7 - WT)7 = \text{Percent per year}$$

in which W7 is the weight, in mg, of the container at 7 days; W14 is the weight, in mg, of the container at 14 days; WT is the tare weight, in g; and 7 is the test time, in days, after the 7-day equilibration period. The containers so tested meet the requirements and are tight containers if the percentage of water weight loss exceeds 2.5% per year in not more than 1 of the 10 test containers and exceeds 5.0% per year in none of them.

#### LIGHT TRANSMISSION TEST

**Apparatus**—Use a spectrophotometer of suitable sensitivity and accuracy, adapted for measuring the amount of light transmitted by either transparent or translucent glass or plastic materials used for pharmaceutical containers. In addition, the spectrophotometer is capable of measuring and recording light transmitted in diffused as well as parallel rays.

**Procedure**—Select sections to represent the average wall thickness. Cut circular sections from two or more areas of the container and trim them as necessary to give segments of a size convenient for mounting in the spectrophotometer. After cutting, wash and dry each specimen, taking care to avoid scratching the surfaces. If the specimen is too small to cover the opening in the specimen holder, mask the uncovered portion of the opening with opaque paper or masking tape, provided that the length of the specimen is greater than that of the slit in the spectrophotometer. Immediately before mounting in the specimen holder, wipe the specimen with lens tissue. Mount the specimen with the aid of a tacky wax, or by other convenient means, taking care to avoid leaving fingerprints or other marks on the surfaces through which light must pass. Place the section in the spectrophotometer with its cylindrical axis parallel to the plane of the slit and approximately centered with respect to the slit. When properly placed, the light beam is normal to the surface of the section and reflection losses are at a minimum.

Continuously measure the transmittance of the section with reference to air in the spectral region of interest with a recording instrument or at intervals of about 20 nm with a manual instrument, in the region of 290 to 450 nm.

**Limits**—The observed light transmission does not exceed the limits given in [Table 2](#) for containers intended for parenteral use.

Table 2. Limits for Plastic Classes I–VI

Nominal Size (in mL)	Maximum Percentage of Light Transmission at Any Wavelength Between 290 and 450 nm	
	Flame-sealed Containers	Closure-sealed Containers
1	50	25
2	45	20
5	40	15
10	35	13
20	30	12
50	15	10

[note—Any container of a size intermediate to those listed above exhibits a transmission not greater than that of the next larger size container listed in the table. For containers larger than 50 mL, the limits for 50 mL apply.]

The observed light transmission for plastic containers for products intended for oral or topical administration does not exceed 10% at any wavelength in the range from 290 to 450 nm.

1 Suitable 4- to 8-mesh, anhydrous calcium chloride is available commercially as Item JT1313-1 from VWR Scientific. Consult the VWR Scientific catalog for ordering information or call 1-800-234-9300.

2 A suitable laminate for sealing has as the container layer polyethylene of not less than 0.025 mm (0.001 inch) and a second layer of aluminum foil of not less than 0.018 mm (0.0007 inch), with additional layers of suitable backing materials. A suitable seal can be obtained also by using glass plates and a sealing wax consisting of 60% of refined amorphous wax and 40% of refined crystalline paraffin wax.

3 Suitable moisture-indicating desiccant pellets are available commercially from sources such as Medical Packaging, Inc., 470 Route 31, Ringoes, NJ 08551-1409 [Telephone 800-257-5282; in NJ, 609-466-8991; FAX 609-466-3775], as Indicating Desiccant Pellets, Item No. TK-1002.

4 Accurate comparisons of Class A containers may require test periods in excess of 28 days if weighings are performed on a Class A prescription balance (see [Prescription Balances and Volumetric Apparatus](#) (1176)). The use of an analytical balance on which weights can be recorded to 4 or 5 decimal places may permit more precise characterization between containers and/or shorter test periods.

Auxiliary Information—Please [check for your question in the FAQs](#) before contacting USP.

## 681 REPACKAGING INTO SINGLE-UNIT CONTAINERS AND UNIT-DOSE CONTAINERS FOR NONSTERILE SOLID AND LIQUID DOSAGE FORMS

This chapter is intended to provide guidance to those engaged in pharmaceutical dispensing, not commercial repackaging. An official dosage form is required to bear on its label an expiration date assigned for the particular formulation and package of the article. This date limits the time during which the product may be dispensed or used. Because the expiration date stated on the original manufacturer's container–closure system has been determined for the drug in that particular system and is not intended to be applicable to the product where it has been repackaged in a different container, repackaged drugs dispensed pursuant to a prescription are exempt from using the expiration date from the original manufacturer's package. However, under no circumstance should the repackaged pharmaceutical preparation's expiration date exceed the original manufacturer's expiration date. It is necessary, therefore, that other precautions be taken by the dispenser to preserve the strength, quality, and purity of drugs that are repackaged for ultimate distribution or sale to patients.

The following guidelines and requirements are applicable where official dosage forms are repackaged into single-unit or unit-dose containers or mnemonic packs for dispensing pursuant to prescription.

**Labeling**—It is the responsibility of the dispenser, taking into account the nature of the drug repackaged, any packaging and expiration dating information in the manufacturer's product labeling, the characteristics of the containers, and the storage conditions to which the article may be subjected, to place a suitable expiration date on the label. Repackaged dosage forms must bear on their labels expiration dates as determined from information in the product labeling (see [Preservation, Packaging, Storage, and Labeling](#) section of the General Notices and Requirements). Each single-unit or unit-dose container bears a separate label, unless the device holding the unit-dose form does not allow for the removal or separation of the intact single-unit or unit-dose container therefrom.

**Storage**—Store the repackaged article in a humidity-controlled environment and at the temperature specified in the individual monograph or in the product labeling. Where no

temperature or humidity is specified in the monograph or in the labeling of the product, controlled room temperature and a relative humidity corresponding to 60% are not to be exceeded during repackaging or storage.

A refrigerator or freezer shall not be considered to be a humidity-controlled environment. Drugs that are to be stored at a cold temperature in a refrigerator or freezer must be protected during storage in the refrigerator or freezer. An outer container may be necessary for such protection; it is recommended that the drug monograph be referenced for storage.

**Reprocessing**— Reprocessing of repackaged unit-dose containers (i.e., removing dosage unit from one unit-dose container and placing dosage unit into another unit-dose container) shall not be done. However, reprocessing of the secondary package (e.g., removing the blister card from the cardboard carrier and placing the blister card into another cardboard carrier) is allowed provided that the original expiration date is maintained.

#### CUSTOMIZED PATIENT MEDICATION PACKAGES

In lieu of dispensing two or more prescribed drug products in separate containers, a pharmacist may, with the consent of the patient, the patient's caregiver, or a prescriber, provide a customized patient medication package (patient med pak).<sup>1</sup>

A patient med pak is a package prepared by a pharmacist for a specific patient comprising a series of containers and containing two or more prescribed solid oral dosage forms. The patient med pak is so designed or each container is so labeled as to indicate the day and time, or period of time, that the contents within each container are to be taken.

It is the responsibility of the dispenser to instruct the patient or caregiver on the use of the patient med pak.

**Label**— The patient med pak shall bear a label stating:

1. the name of the patient;
2. a serial number for the patient med pak itself and a separate identifying serial number for each of the prescription orders for each of the drug products contained therein;
3. the name, strength, physical description or identification, and total quantity of each drug product contained therein;
4. the directions for use and cautionary statements, if any, contained in the prescription order for each drug product therein;
5. any storage instructions or cautionary statements required by the official compendia;
6. the name of the prescriber of each drug product;
7. the date of preparation of the patient med pak and the beyond-use date or period of time assigned to the patient med pak (such beyond-use date or period of time shall be not longer than the shortest recommended beyond-use date for any dosage form included therein or not longer than 60 days from the date of preparation of the patient med pak and shall not exceed the shortest expiration date on the original manufacturer's bulk containers for the dosage forms included therein); alternatively, the package label shall state the date of the prescription(s) or the date of preparation of the patient med pak, provided the package is accompanied by a record indicating the start date and the beyond-use date;
8. the name, address, and telephone number of the dispenser (and the dispenser's registration number where necessary); and
9. any other information, statements, or warnings required for any of the drug products contained therein.

If the patient med pak allows for the removal or separation of the intact containers therefrom, each individual container shall bear a label identifying each of the drug products contained therein.

**Labeling**— The patient med pak shall be accompanied by a patient package insert, in the event that any medication therein is required to be dispensed with such insert as accompanying labeling. Alternatively, such required information may be incorporated into a single, overall educational insert provided by the pharmacist for the total patient med pak.

**Packaging**— In the absence of more stringent packaging requirements for any of the drug products contained therein, each container of the patient med pak shall comply with the moisture permeation requirements for a Class B single-unit or unit-dose container (see [Containers—Permeation \(671\)](#)). Each container shall be either not reclosable or so designed as to show evidence of having been opened.

**Guidelines**— It is the responsibility of the dispenser, when preparing a patient med pak, to take into account any applicable compendial requirements or guidelines and the physical and chemical compatibility of the dosage forms placed within each container, as well as any therapeutic incompatibilities that may attend the simultaneous administration of the medications. In this regard, pharmacists are encouraged to report to USP headquarters any observed or reported incompatibilities. Once a medication has been placed in a patient med pak with another solid dosage form, it may not be returned to stock, redistributed, or resold if unused.

**Recordkeeping**— In addition to any individual prescription filing requirements, a record of each patient med pak shall be made and filed. Each record shall contain, as a minimum:

1. the name and address of the patient;
2. the serial number of the prescription order for each drug product contained therein;
3. the name of the manufacturer or labeler and lot number for each drug product contained therein;
4. information identifying or describing the design, characteristics, or specifications of the patient med pak sufficient to allow subsequent preparation of an identical patient med pak for the patient;
5. the date of preparation of the patient med pak and the beyond-use date that was assigned;
6. any special labeling instructions; and
7. the name or initials of the pharmacist who prepared the patient med pak.

<sup>1</sup> It should be noted that there is no special exemption for patient med paks from the requirements of the Poison Prevention Packaging Act. Thus the patient med pak, if it does not meet child-resistant standards, shall be placed in an outer package that does comply, or the necessary consent of the purchaser or physician, to dispense in a container not intended to be child-resistant, shall be obtained.

**Auxiliary Information**— Please [check for your question in the FAQs](#) before contacting USP.

USP32-NF27 Page 253

Pharmacopeial Forum: Volume No. 32(4) Page 1197

691 COTTON

Preparatory to the determination of absorbency and of fiber length, remove the Cotton from its wrappings, and condition it for not less than 4 hours in a standard atmosphere of  $65 \pm 2\%$  relative humidity at  $21 \pm 1.1^{\circ}\text{F}$  ( $70 \pm 2^{\circ}\text{F}$ ).

#### Absorbency Test

**Procedure**— Prepare a test basket, weighing not more than 3 g, from copper wire approximately 0.4 mm in diameter (No. 26 B. & S.) in the form of a cylinder approximately 5 cm in diameter and 8 cm deep, with spaces of about 2 cm between the wires. Take portions of purified cotton weighing  $1 \pm 0.05$  g from five different parts of the package by pulling, not cutting, the specimens, place the combined portions in the basket, and weigh. Hold the basket on its side approximately 12 mm above the surface of water at  $25 \pm 1^{\circ}\text{F}$ , and drop it into the water. Determine, preferably by use of a stop watch, the time in seconds required for complete submersion.

Remove the basket from the water, allow it to drain for 10 seconds in the same horizontal position, then place it immediately in a tared, covered vessel, and weigh, deducting the weight of the test basket and of the purified cotton to find the weight of water absorbed.

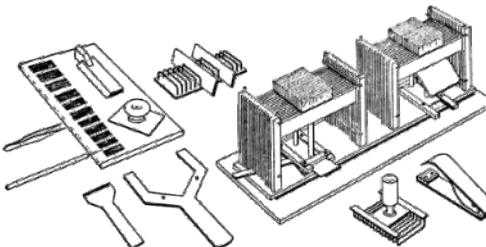

## Fiber Length

For the determination of the length and of the length distribution of cotton fibers in purified cotton use the following method:

Carry out all operations associated with the determination of fiber length of purified cotton in an atmosphere maintained at  $65 \pm 2\%$  relative humidity at  $21 \pm 1.1^{\circ}$  ( $70 \pm 2^{\circ}$  F).

These directions describe the mode of procedure that is well adapted to the sorter\* most extensively used in the United States at the present time.

Apparatus— The sorter (see [Illustration](#))

Duplex Cotton Fiber Sorter

consists of two banks of combs rigidly mounted side by side on a common base. Each bank of combs consists of at least 12 individual combs spaced 3.2 mm apart, one behind the other, and mounted in grooves so that as they are approached during the fractionating process and no longer needed, they may be dropped below the working plane. Each individual comb has a single row of accurately aligned and sharply pointed teeth, 12 mm long, consisting of needles 0.38 mm in diameter. The teeth are spaced 62 to 25 mm over an extent of approximately 50 mm.

Accessory equipment consists of fiber-sorter forceps, fiber-depressing grid, fiber-depressing smooth plate, and velvet-covered plates. The sorter forceps consist of two brass pieces approximately 75 mm long, hinged on one end and slightly curved to present a beaked aspect at the gripping end for gripping the protruding fibers close to the surfaces of the combs.

Usually, one of the gripping edges has a leather or other fibrous padding. The gripping edge is approximately 19 mm wide.

The fiber-depressing grid consists of a series of brass rods spaced 3.2 mm apart so that they may be placed between the combs to press the fibers down between the teeth. The fiber-depressing smooth plate consists of a polished brass plate approximately  $25 \times 50$  mm, with a knob or handle on the upper surface whereby the plate may be smoothed over the fibers as they are laid on the velvet surface of the array plates. The velvet-covered plates, upon which the fibers may be arrayed, are aluminum sheets approximately  $100 \text{ mm} \times 225 \text{ mm} \times 2.4 \text{ mm}$  thick, covered on both sides with high-grade velvet, preferably black.

Selection of Cotton— After unrolling the cotton, prepare a representative laboratory test specimen by taking from a package containing from 8 to 16 ounces, 32 pinches (about 75 mg each) well distributed throughout the bulk of the lap, 16 representative pinches being taken from each longitudinal half of the lap. Avoid the cut ends of the lap, and take particular care to secure portions throughout the thickness of the lap. To avoid biased selection of long or short fibers, remove all fibers of the group pinched and do not allow them to slip from between the fingers.

From packages of not more than 4 ounces in weight, take 8 pinches, and from packages weighing more than 4 ounces and not more than 8 ounces, take 16 pinches, all well distributed.

Mix the pinches in pairs promiscuously, and combine each pair by gently drawing and lapping them in the fingers. Then divide each combined pair by splitting longitudinally into two approximately equal parts and utilize one part in the further mixing. (The other part may be discarded or reserved for any further tests or checks.)

Repeat the process described in the preceding paragraph with the successive halves of the bifurcated series until only 1 pinch, the final composite test portion, results. Gently parallel and straighten the fibers of the final composite test portion by drawing and lapping them in the fingers. Take care to retain all of the fibers, including as far as possible those of the neps (specks of entangled fibers) and naps (matted masses of fibers), discarding only motes (immature seed fragments with fibers) and nonfiber foreign material such as stem, leaf, and fragments of seedcoats.

From the final composite portion described in the preceding paragraph, separate longitudinally a test portion of  $75 \pm 2$  mg, accurately weighed. Retain the residue for any check test necessary.

Procedure— With the fiber-depressing grid carefully insert the weighed test portion into one bank of combs of the cotton sorter, so that it extends across the combs at approximately right angles.

With the sorter forceps, grip by the free ends a small portion of the fibers extending through the teeth of the comb nearest to the operator; gently and smoothly draw them forward out of the combs, and transfer them to the tips of the teeth in the second bank of combs, laying them parallel to themselves, straight, and approximately at right angles to the faces of the combs, releasing the gripped ends as near to the face of the front comb as possible. With the depressor grid carefully press the transferred fibers down into the teeth of the combs. Continue the operation until all of the fibers are transferred to the second bank of combs. During this transfer of the fibers, drop the combs of the first bank in succession when and as all of the protruding fibers have been removed.

Turn the machine through  $180^{\circ}$ , and transfer the cotton fibers back to the first bank of combs in the manner described in the preceding paragraph.

Take great care in evening up the ends of the fibers during both of the above transfers, arranging them as closely as possible to the front surface of the proximal comb. Such evening out of the ends of the protruding fibers may involve drawing out straggling fibers from both the front and rear aspects of the banks of combs, and re-depositing them into and over the main bundle in the combs.

Turn the machine again through  $180^{\circ}$ . Drop successive combs if necessary to expose the ends of the longest fibers. It may be necessary to re-deposit some straggling fibers. With the forceps withdraw the few most protuberant fibers. In this way continue to withdraw successively the remaining protuberant fibers back to the front face of the proximal comb. Drop this comb and repeat the series of operations in the same manner until all of the fibers have been drawn out. In order not to disturb seriously the portion being tested, and thereby vitiate the length fractionation into length groups, make several pulls (as many as 8 to 10) between each pair of combs.

Lay the pulls on the velvet-covered plates alongside each other, as straight as possible, with the ends as clearly defined as possible, and with the distal ends arranged in a straight line, pressing them down gently and smoothly with the fiber-depressing smooth plate before releasing the pull from the forceps. Employ not fewer than 50 and not more than 100 pulls to fractionate the test portion.

Group together all of the fibers measuring 12.5 mm (about 1/2 inch) or more in length, and weigh the group to the nearest 0.3 mg. In the same manner, group together all fibers 6.25 mm (about 1/4 inch) or less in length, and weigh in the same manner. Finally, group the remaining fibers of intermediate lengths together and weigh. The sum of the three weights does not differ from the initial weight of the test portion by more than 3 mg. Divide the weight of each of the first two groups by the weight of the test portion to obtain the percentage by weight of fiber in the two ranges of length.

\* note—The method here described is especially adapted to the Suter-Webb Duplex Cotton Fiber sorting apparatus, but with more or less obvious alteration in procedure, may be carried out with two Baer sorters in tandem arrangement, or with a Johannsen or other similar apparatus.

### 696 CRYSTALLINITY DETERMINATION BY SOLUTION CALORIMETRY

#### INTRODUCTION—THE CONCEPT OF CRYSTALLINITY

The perfectly ordered crystal lattice with every molecule in its expected lattice position is an ideal that is seldom, if ever, achieved. The other extreme is the amorphous state, in which a crystal contains the maximum possible density of imperfections (defects of various dimensionalities), such that all long-range order is lost while only the short-range order, imposed by its nearest molecular neighbors, remains. Real crystals lie somewhere between these two extremes. A crystal's position on a scale bounded by these two extremes is termed its crystallinity.

All real crystals, even in the pure state, possess some lattice imperfections or defects, which increase both the energy (enthalpy under conditions of constant atmospheric pressure) and the disorder (expressed as the entropy) of the crystal lattice. A crystal with a relatively small density of imperfections is said to be highly crystalline and to possess a high crystallinity. By contrast, a particle with a relatively high density of imperfections is said to be partially amorphous and to possess a low crystallinity. A totally amorphous particle corresponds to zero crystallinity. Even amorphous particles may contain domains of somewhat ordered molecules that can act as nuclei for crystallization; such so-called amorphous particles are said to possess a small but finite crystallinity.

For a powder or a collection of particles, two models of crystallinity have been proposed: the one-state model and the two-state model. According to the one-state model, all particles in the powder possess essentially the same crystallinity. By contrast, the two-state model postulates that each particle in a powder may be either crystalline or amorphous, such that the actual crystallinity is the weighted average of these two extreme crystallinities. In reality, a powder probably contains particles with different degrees of crystallinity, just as it may contain particles with different sizes and shapes. The lower the crystallinity of a particle, the greater its enthalpy and entropy. The increase in enthalpy is never totally compensated by the increase in entropy; however, the Gibbs free energy, which reflects the balance between them, actually increases. Hence, the lower the crystallinity of a particle, and consequently the greater its amorphous character, the greater its apparent intrinsic solubility, dissolution rate, and reactivity, but the lower its stability. Because of the great relevance of these properties, crystallinity is also an important property and requires measurement by a suitable method.

Various methods are available for the measurement of crystallinity. In the present chapter, the crystallinity of a powder is measured by solution calorimetry, although other methods could be used provided they have been validated.

#### DETERMINING CRYSTALLINITY BY SOLUTION CALORIMETRY

Solution calorimetry provides a means of determining enthalpy of solution (i.e., heat of solution under constant atmospheric pressure) of a solid substance. Enthalpy of solution may be defined as the enthalpy of the substance dissolved in the solution to a defined concentration minus the enthalpy of the original solid substance. The solvent for the solution process must be such that the weight of the solid taken (25 to 100 mg) dissolves within a time frame that matches the response time of the calorimeter, as discussed below. The enthalpy of solution is, of course, proportional to the amount of solid being dissolved. This amount may be defined as one mole for molar enthalpy or as one gram for specific enthalpy. If the substance is pure and if its molecular weight is known, the molar enthalpy is preferred, otherwise the specific enthalpy must be used. The enthalpy of solution is weakly dependent on both the temperature, which is usually 25.0°, and the final concentration of the dissolved solute, which is usually on the order of 50 to 200 mg per 100 mL of solvent.

The crystallinity of the solid sample under study is given by the enthalpy of solution of the solid sample  $\Delta H^s_x$ , minus the enthalpy of solution of the chosen reference standard of the same substance,  $\Delta H^s_R$ , when determined under the same conditions. Because the reference standard is usually chosen for its perceived high crystallinity, its enthalpy of solution usually is algebraically greater (more endothermic or less exothermic) than that of the solid sample under study in the same solvent. Consequently, the crystallinity so determined is a negative quantity with the SI units, kJ/mol or J/g (J/kg is avoided because of its unwieldiness and potential for error). The preference for a negative value with respect to a highly crystalline reference standard recognizes the fact that most samples have a lower crystallinity than this reference standard.

A number of substances, including some purified by freeze-drying, may be available in an amorphous form but not in a crystalline form. With such substances, an amorphous form, prepared by a standard procedure, may be used as the reference standard. The enthalpy of solution may then be algebraically smaller than that of the chosen amorphous reference standard, in which case the crystallinity, as defined above, has a positive value.

The use of a single reference standard for each solid substance provides a single crystallinity scale, expressed in terms of energy, for each substance and recognizes that each solid drug or excipient has unique properties. Furthermore, the crystallinity can be recalculated—if the original reference standard is later replaced by a more crystalline (or more amorphous) reference standard—because enthalpies of solution are additive quantities according to Hess's Law of constant heat summation (i.e., the first law of thermodynamics).

In principle, the determination of the crystallinity of polymers may also be carried out using solution calorimetry, but this requires a defined reference standard for the polymer and a solvent in which the polymer is sufficiently soluble as discussed below.

Because the enthalpy of solution depends not only on the crystallinity of the solid but also on the various other solute–solute intermolecular interactions and on the solute–solvent and solvent–solvent intermolecular interactions, a zero value for the enthalpy of solution does not necessarily indicate zero crystallinity of the solid solute.

It is sometimes preferred to express the crystallinity,  $P_c$ , of a substance on a percentage scale, as described by Pikal et al.,<sup>1</sup> who also provide references to relevant earlier literature. This procedure requires two reference standards, namely a highly crystalline sample representing 100% crystallinity and having a measured enthalpy of solution of  $\Delta H^s_c$ , and an essentially amorphous sample representing 0% crystallinity and having a measured enthalpy of solution of  $\Delta H^s_a$ . From these values and from the measured enthalpy,  $\Delta H^s_s$ , of solution of the solid under study, the percentage crystallinity of the solid,  $P_c$ , may be calculated as follows:

$$P_c (\%) = 100(\Delta H^s_s - \Delta H^s_a)/(\Delta H^s_c - \Delta H^s_a)$$

Clearly, crystallinity expressed on a percentage scale depends on three, not two, measured values and the enthalpies of solution may be replaced by other corresponding physical

quantities that depend on crystallinity. The value of the percentage crystallinity of a solid sample, however, depends not only on the nature and method of preparation of the two reference standards, but also on the choice of the physical quantity that is measured.

The enthalpy of solution is measured at  $25.0 \pm 0.1^\circ$  either by an isoperibol (constant perimeter, i.e., jacket) solution calorimeter or by an isothermal (constant temperature) solution calorimeter using a fixed weight from 25 to 100 mg of solid sample, weighed to  $\pm 0.1$  mg, with a fixed weight of solvent from 25 to 100 g, weighed to 0.01 g (usually  $50.00 \pm 0.01$  g). The weight of solid solute and the nature of the solvent should be so chosen that the enthalpy of solution is not less than 200 mJ. At least three measurements are made with each sample, if a sufficient quantity is available, until the measured values of the heat of solution do not differ by more than 5%. The arithmetic mean of these three values is then calculated.

#### Isoperibol Solution Calorimetry

In the isoperibol solution calorimeter, the heat change during the solution process causes a corresponding change in temperature of the solvent–solute system (i.e., solution). This temperature change is measured by a temperature sensor, which is wired to an electrical circuit that records an electrical signal corresponding to the temperature change. Typically, this temperature change in an electronic form is measured at precisely defined time intervals to produce temperature–time data that are collected, analyzed by a computer, and then plotted. A blank run without addition of the solid solute to the solvent should show no discernible change in the slope of the temperature–time plot.

For isoperibol solution calorimeters, response is relatively rapid, but any heat losses to or heat gains from the bath reduce the accuracy and contribute to noise. Therefore, isoperibol solution calorimeters are more advantageous than isothermal solution calorimeters when the solution process is relatively fast. For all measurements of enthalpy of solution using isoperibol solution calorimeters, the choice of solvent and solid is critical. The nature and weight of the solvent and the weight of the solid sample allow the total heat change, corresponding to total dissolution of the solid, to proceed to completion within 10 minutes under vigorous stirring at a constant rotational speed within the range of 400 to 600 revolutions per minute. The rotational speed is checked with a stroboscope.

#### Isothermal Solution Calorimetry

In the isothermal (constant temperature) solution calorimeter, the heat change during the solution process is compensated for by an equal but opposite energy change, such that the temperature of the solvent–solute system (i.e., solution) remains constant. This equal but opposite energy change is measured and, when its sign is reversed, provides the enthalpy of solution. For isothermal calorimeters, response is relatively slow, but the compensation process eliminates the effects of heat losses to or heat gains from the bath. Therefore, isothermal calorimeters are more advantageous than isoperibol calorimetry when the solution process is relatively slow.

#### CALORIMETER CALIBRATION

To ensure the accuracy of the calorimeter, chemical calibrations must be performed daily. For an endothermic solution process, the calibration of the calorimeter is checked by measuring the heat absorbed during the dissolution of potassium chloride in distilled water at  $298.15\text{ K}$  ( $25.0^\circ$ ). The established enthalpy change in this endothermic process is  $235.5\text{ J/g}$  or  $4.196\text{ kcal/mol}$ . For an exothermic solution process, the calorimeter is checked by measuring the heat evolved during the dissolution of  $5\text{ g}$  per  $\text{L}$  of tromethamine [tris(hydroxymethyl)aminomethane, THAM] in a  $0.1\text{ mol/L}$  aqueous hydrochloric acid solution at  $298.15\text{ K}$  ( $25.0^\circ$ ). The established heat for the aforementioned process is  $-29.80\text{ kJ/mol}$  or  $-7.12\text{ kcal/mol}$ .

The effective heat capacity of the calorimeter cell and its contents is determined for every calorimeter run. This determination is accomplished by electrical heating of the contents of the calorimeter cell. The effective heat capacity is determined according to one of two protocols—either by making one determination after ampul breakage or by making one determination before and a second determination after ampul breakage and then averaging the two results. The accuracy and reliability of the electrical heating are established by the accuracy and reliability of the aforementioned chemical calibrations.

#### SAMPLE HANDLING

The thermodynamic stability of solids decreases with decreasing crystallinity. In particular, solids of low crystallinity, especially amorphous solids, tend to sorb water vapor from the atmosphere, leading to crystallization and a corresponding gain in crystallinity. For these reasons, anhydrous solid samples whose crystallinity is to be determined must be stored at zero humidity in sealed chambers containing a desiccant, preferably containing an indicator of effectiveness. If crystallinity–humidity studies are to be carried out, the solid sample should be stored in a sealed chamber containing a saturated salt solution to provide a defined relative humidity at  $25.0 \pm 0.1^\circ$ .

USP32–NF27 Page 256

Pharmacopeial Forum: Volume No. 29(1) Page 175

#### 698 DELIVERABLE VOLUME

The following tests are designed to provide assurance that oral liquids will, when transferred from the original container, deliver the volume of dosage form that is declared on the label of the article. These tests are applicable to products labeled to contain not more than 250 mL, whether supplied as liquid preparations or liquid preparations that are constituted from solids upon the addition of a designated volume of a specific diluent. They are not required for an article packaged in single-unit containers when the monograph includes the

[Uniformity of Dosage Units](#) [905](#) test.

#### TEST PREPARATIONS

For the determination of deliverable volume, select not fewer than 30 containers, and proceed as follows for the dosage form designated.

Oral Solutions, Oral Suspensions, and Other Oral Liquid Dosage Forms—Shake the contents of 10 containers individually.

Powders that are Labeled to State the Volume of Oral Liquid that Results when the Powder is Constituted with the Volume of Diluent Stated in the Labeling—Constitute 10 containers with the volume of diluent stated in the labeling, accurately measured, and shake individually.

#### PROCEDURE

Being careful to avoid the formation of air bubbles, gently pour the contents of each container into separate dry graduated cylinders of a rated capacity not exceeding two and a half times the volume to be measured, and calibrated “to contain”. Allow each container to drain for a period not to exceed 30 minutes, for multiple-unit containers and 5 seconds for single-unit containers, unless otherwise specified in the monograph. When free from air bubbles, measure the volume of each mixture. Alternatively, in the case of products of low volume packaged in single-unit containers, the volume can be computed as follows: (1) discharge the container contents into a suitable tared container (allowing drainage for not more than 5 seconds); (2) determine the weight of the contents; and (3) compute the volume after determining the density.

## ACCEPTANCE CRITERIA

Use the following criteria to determine compliance with this test.

For Multiple-Unit Containers (see [Figure 1](#))— The average volume of liquid obtained from the 10 containers is not less than 100%, and the volume of no container is less than 95% of the volume declared in the labeling. If A, the average volume is less than 100% of that declared in the labeling, but the volume of no container is less than 95% of the labeled amount, or B, the average volume is not less than 100% and the volume of not more than 1 container is less than 95%, but is not less than 90% of the labeled volume, perform the test on 20 additional containers. The average volume of liquid obtained from the 30 containers is not less than 100% of the volume declared in the labeling; and the volume of liquid obtained from not more than 1 of the 30 containers is less than 95%, but not less than 90% of that declared in the labeling.

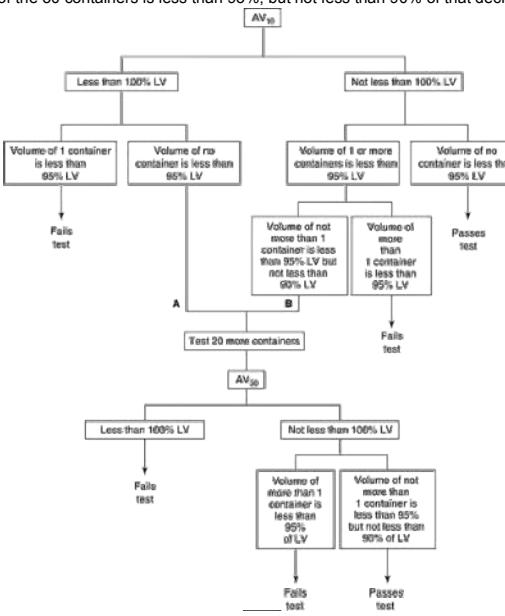

Figure 1. Decision scheme for multiple-unit containers. (AV = Average volume. LV = Labeled volume)

For Single-Unit Containers (see [Figure 2](#))— The average volume of liquid obtained from the 10 containers is not less than 100%, and the volume of each of the 10 containers lies within the range of 95% to 110% of the volume declared in the labeling. If A, the average volume is less than 100% of that declared in the labeling, but the volume of no container is outside the range of 95% to 110%, or if B, the average volume is not less than 100% and the volume of not more than 1 container is outside the range of 95% to 110%, but within the range of 90% to 115%, perform the test on 20 additional containers. The average volume of liquid obtained from the 30 containers is not less than 100% of the volume declared in the labeling; and the volume obtained from not more than 1 of the 30 containers is outside the range of 95% to 110%, but within the range of 90% to 115% of the volume declared on the labeling.

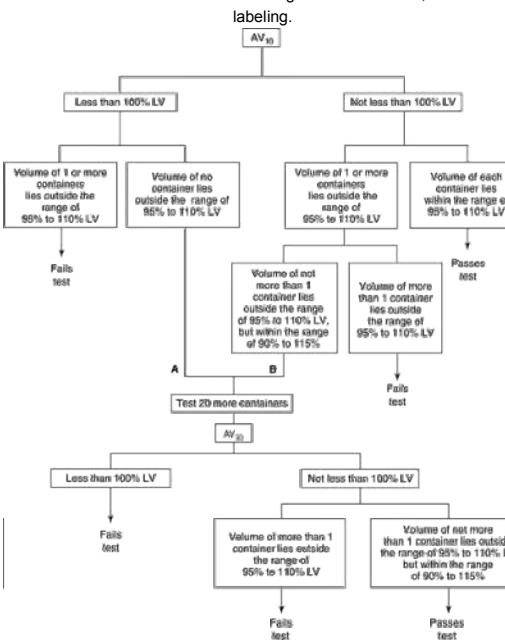

Figure 2. Decision scheme for single-unit containers. (AV = Average volume. LV = Labeled volume)

Topic/Question	Contact	Expert Committee
General Chapter	<a href="#">William E. Brown</a> Senior Scientist 1-301-816-8380	(PDF05) Pharmaceutical Dosage Forms 05

Density refers to the average spatial distribution of mass in a material. The density of solids typically is expressed in g per cm<sup>3</sup>, in contrast to fluids, where the density is commonly expressed in g per mL at a stated reference temperature.

The density of a solid particle can assume different values depending on the method used to measure the volume of the particle. It is useful to distinguish among three different possibilities.

The true density of a substance is the average mass per unit volume, exclusive of all voids that are not a fundamental part of the molecular packing arrangement. It is a property of a particular material, and hence should be independent of the method of determination. The true density of a perfect crystal can be determined from the size and composition of the unit cell.

The pycnometric density, as measured by gas pycnometry, is a convenient density measurement for pharmaceutical powders. In a gas pycnometer, the volume occupied by a known mass of powder is determined by measuring the volume of gas displaced by the powder. The quotient of the mass and volume is the pycnometric density. The pycnometric density equals the true density unless the material contains impenetrable voids, or sealed pores, that are inaccessible to the gas used in the pycnometer.

The granular density includes contributions to particle volume from open pores smaller than some limiting size. The size limit depends on the method of measurement. A common measurement technique is mercury porosimetry, where the limiting pore size depends upon the maximum intrusion pressure. Because of the additional contribution from pore volume, the granular density will never be greater than the true density. A related concept is the aerodynamic density, which is the density of the particle with a volume defined by the aerodynamic envelope of the particle in a flowing stream. Both the closed and open pores contribute to this volume, but the open pores fill with the permeating fluid. The aerodynamic density, therefore, depends on the density of the test fluid if the particle is porous.

For brevity, the pycnometric density and the true density are both referred to as density. If needed, these quantities may be distinguished based on the method of measurement.

The density of a material depends on the molecular packing. For gases and liquids, the density will depend only on temperature and pressure. For solids, the density will also vary with the crystal structure and degree of crystallinity. If the solids are amorphous, the density may further depend upon the history of preparation and treatment. Therefore, unlike fluids, the densities of two chemically equivalent solids may be different, and this difference reflects a difference in solid-state structure. The density of constituent particles is an important physical characteristic of pharmaceutical powders.

Beyond these definitions of particle density, the bulk density of a powder includes the contribution of interparticulate void volume. Hence, the bulk density depends on both the density of powder particles and the packing of powder particles.

#### GAS PYCNOMETRY FOR THE MEASUREMENT OF DENSITY

Gas pycnometry is a convenient and suitable method for the measurement of the density of powder particles. A simple schematic of one type of gas pycnometer is shown in [Figure 1](#).

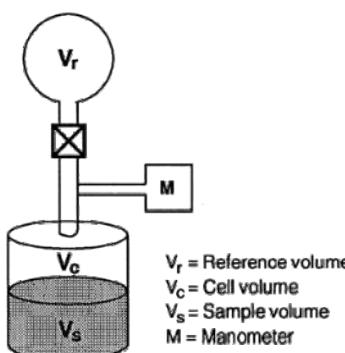

Fig. 1. Schematic of Gas Pycnometer.

The sample, with mass  $w$  and volume  $V_s$ , is placed inside a sealed test cell with an empty cell volume of  $V_c$ . The system reference pressure,  $P_r$ , is determined at the manometer while the valve that connects the reference volume with the test cell is open. The valve is closed to separate the reference volume,  $V_r$ , from the test cell. The test cell is pressurized with the measurement gas to an initial pressure,  $P_i$ . Then the valve is opened to connect the reference volume,  $V_r$ , with the test cell, and the pressure drops to the final pressure,  $P_f$ . If the measurement gas behaves ideally under the conditions of measurement, the sample volume,  $V_s$ , is given by the following expression:

$$V_s = V_c + \frac{V_r}{1 - \left[ \frac{P_i - P_r}{P_f - P_r} \right]} \quad (1)$$

The density,  $\rho$ , is given by the equation:

$$\rho = \frac{w}{V_s} \quad (2)$$

Details of the instrumental design may differ, but all gas pycnometers rely on the measurement of pressure changes as a reference volume is added to, or deleted from, the test cell.

The measured density is a volume-weighted average of the densities of individual powder particles. The density will be in error if the test gas sorbs onto the powder or if volatile contaminants are evolved from the powder during the measurement. Sorption is prevented by an appropriate choice of test gas. Helium is the common choice. Volatile contaminants in the powder are removed by degassing the powder under a constant purge of helium prior to the measurement. Occasionally, powders may have to be degassed under vacuum. Two

Consecutive readings should yield sample volumes that are equal within 0.2% if volatile contaminants are not interfering with the measurements. Because volatiles may be evolved during the measurement, the weight of the sample should be taken after the pycnometric measurement of volume.

#### Method

Ensure that the reference volume and the calibration volume have been determined for the gas pycnometer by an appropriate calibration procedure. The test gas is helium, unless another gas is specified in the individual monograph. The temperature of the gas pycnometer should be between 15° and 30° and should not vary by more than 2° during the course of the measurement. Load the test cell with the substance under examination that has been prepared according to the individual monograph. Where 699D is indicated, dry the substance under examination as directed for Loss on drying in the monograph unless other drying conditions are specified in the monograph Density of solids test. Where 699U is indicated, the substance under examination is used without drying. Use a quantity of powder recommended in the operating manual for the pycnometer. Seal the test cell in the pycnometer, and purge the pycnometer system with the test gas according to the procedure given in the manufacturer's operating instructions. If the sample must be degassed under vacuum, follow the recommendations in the individual monographs and the instructions in the operating manual for the pycnometer.

The measurement sequence above describes the procedure for the gas pycnometer shown in [Figure 1](#). If the pycnometer differs in operation or in construction from the one shown in [Figure 1](#), follow the operating procedure given in the manual for the pycnometer.

Repeat the measurement sequence for the same powder sample until consecutive measurements of the sample volume,  $V_s$ , agree to within 0.2%. Unload the test cell and measure the final powder weight,  $w$ . Calculate the pycnometric density,  $P$ , of the sample according to Equation 2.

Auxiliary Information— Please [check your question in the FAQs](#) before contacting USP.

Change to read:

701 DISINTEGRATION

This general chapter is harmonized with the corresponding texts of the European Pharmacopoeia and/or the Japanese Pharmacopoeia. The texts of these pharmacopoeias are therefore interchangeable, and the methods of the European Pharmacopoeia and/or the Japanese Pharmacopoeia may be used for demonstration of compliance instead of the present general chapter. These pharmacopoeias have undertaken not to make any unilateral change to this harmonized chapter.

Portions of the present general chapter text that are national USP text, and therefore not part of the harmonized text, are marked with symbols (♦) to specify this fact.

This test is provided to determine whether tablets or capsules disintegrate within the prescribed time when placed in a liquid medium at the experimental conditions presented below.

♦ Compliance with the limits on Disintegration stated in the individual monographs is required except where the label states that the tablets or capsules are intended for use as troches, or are to be chewed, or are designed as extended-release dosage forms or delayed-release dosage forms. Determine the type of units under test from the labeling and from observation, and apply the appropriate procedure to 6 or more dosage units.♦

For the purposes of this test, disintegration does not imply complete solution of the unit or even of its active constituent. Complete disintegration is defined as that state in which any residue of the unit, except fragments of insoluble coating or capsule shell, remaining on the screen of the test apparatus or adhering to the lower surface of the disk, if used, is a soft mass having no palpably firm core.

#### APPARATUS

The apparatus consists of a basket-rack assembly, a 1000-mL, low-form beaker, 138 to 160 mm in height and having an inside diameter of 97 to 115 mm for the immersion fluid, a thermostatic arrangement for heating the fluid between 35° and 39°, and a device for raising and lowering the basket in the immersion fluid at a constant frequency rate between 29 and 32 cycles per minute through a distance of not less than 53 mm and not more than 57 mm. The volume of the fluid in the vessel is such that at the highest point of the upward stroke the wire mesh remains at least 15 mm below the surface of the fluid and descends to not less than 25 mm from the bottom of the vessel on the downward stroke. At no time should the top of the basket-rack assembly become submerged. The time required for the upward stroke is equal to the time required for the downward stroke, and the change in stroke direction is a smooth transition, rather than an abrupt reversal of motion. The basket-rack assembly moves vertically along its axis. There is no appreciable horizontal motion or movement of the axis from the vertical.

**Basket-Rack Assembly—** The basket-rack assembly consists of six open-ended transparent tubes, each  $77.5 \pm 2.5$  mm long and having an inside diameter of 20.7 to 23 mm and a wall 1.0 to 2.8 mm thick; the tubes are held in a vertical position by two plates, each 88 to 92 mm in diameter and 5 to 8.5 mm in thickness, with six holes, each 22 to 26 mm in diameter, equidistant from the center of the plate and equally spaced from one another. Attached to the under surface of the lower plate is a woven stainless steel wire cloth, which has a plain square weave with 1.8- to 2.2-mm apertures and with a wire diameter of 0.57 to 0.66 mm. The parts of the apparatus are assembled and rigidly held by means of three bolts passing through the two plates. A suitable means is provided to suspend the basket-rack assembly from the raising and lowering device using a point on its axis.

The design of the basket-rack assembly may be varied somewhat, provided the specifications for the glass tubes and the screen mesh size are maintained. The basket-rack assembly conforms to the dimensions found in [Figure 1](#).

**Disk—** The use of disks is permitted only where specified or allowed in the monograph. If specified in the individual monograph, each tube is provided with a cylindrical disk  $9.5 \pm 0.15$  mm thick and  $20.7 \pm 0.15$  mm in diameter. The disk is made of a suitable transparent plastic material having a specific gravity of between 1.18 and 1.20. Five parallel  $2 \pm 0.1$ -mm holes extend between the ends of the cylinder. One of the holes is centered on the cylindrical axis. The other holes are centered  $6 \pm 0.2$  mm from the axis on imaginary lines perpendicular to the axis and parallel to each other. Four identical trapezoidal-shaped planes are cut into the wall of the cylinder, nearly perpendicular to the ends of the cylinder. The trapezoidal shape is symmetrical; its parallel sides coincide with the ends of the cylinder and are parallel to an imaginary line connecting the centers of two adjacent holes 6 mm from the cylindrical axis. The parallel side of the trapezoid on the bottom of the cylinder has a length of  $1.6 \pm 0.1$  mm, and its bottom edges lie at a depth of  $1.5$  to  $1.8$  mm (RB 1-Aug-2008) from the cylinder's circumference. The parallel side of the trapezoid on the top of the cylinder has a length of  $9.4 \pm 0.2$  mm, and its center lies at a depth of  $2.6 \pm 0.1$  mm from the cylinder's circumference. All surfaces of the disk are smooth. If the use of disks is specified in the individual monograph, add a disk to each tube, and operate the apparatus as directed under Procedure. The disks conform to dimensions found in [Figure 1](#).

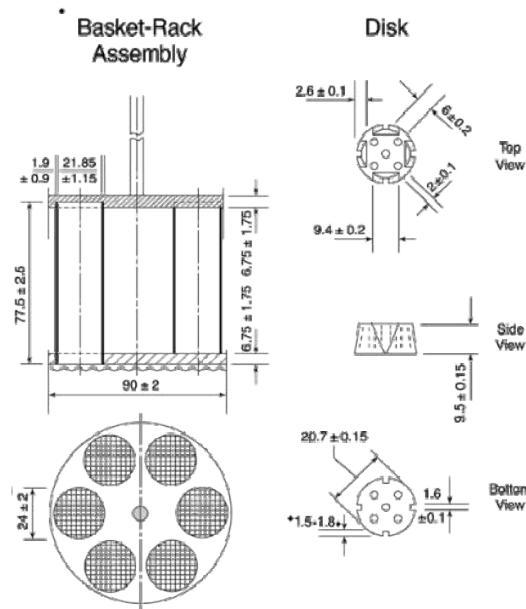

Figure 1. Disintegration apparatus. (All dimensions are expressed in mm.)\* (RB 1-Aug-2008)

## PROCEDURE

Uncoated Tablets— Place 1 dosage unit in each of the six tubes of the basket and, if prescribed, add a disk. Operate the apparatus, using water or the specified medium as the immersion fluid, maintained at  $37 \pm 2^\circ\text{C}$ . At the end of the time limit specified in the monograph, lift the basket from the fluid, and observe the tablets: all of the tablets have disintegrated completely. If 1 or 2 tablets fail to disintegrate completely, repeat the test on 12 additional tablets. The requirement is met if not fewer than 16 of the total of 18 tablets tested are disintegrated.

Plain-Coated Tablets— Apply the test for Uncoated Tablets, operating the apparatus for the time specified in the individual monograph.

Delayed-Release (Enteric-Coated) Tablets— Place 1 tablet in each of the six tubes of the basket and, if the tablet has a soluble external sugar coating, immerse the basket in water at room temperature for 5 minutes. Then operate the apparatus using simulated gastric fluid TS maintained at  $37 \pm 2^\circ\text{C}$  as the immersion fluid. After 1 hour of operation in simulated gastric fluid TS, lift the basket from the fluid, and observe the tablets: the tablets show no evidence of disintegration, cracking, or softening. Operate the apparatus, using simulated intestinal fluid TS maintained at  $37 \pm 2^\circ\text{C}$  as the immersion fluid, for the time specified in the monograph. Lift the basket from the fluid, and observe the tablets: all of the tablets disintegrate completely. If 1 or 2 tablets fail to disintegrate completely, repeat the test on 12 additional tablets: not fewer than 16 of the total of 18 tablets tested disintegrate completely.

Buccal Tablets— Apply the test for Uncoated Tablets. After 4 hours, lift the basket from the fluid, and observe the tablets: all of the tablets have disintegrated. If 1 or 2 tablets fail to disintegrate completely, repeat the test on 12 additional tablets: not fewer than 16 of the total of 18 tablets tested disintegrate completely.

Sublingual Tablets— Apply the test for Uncoated Tablets. At the end of the time limit specified in the individual monograph: all of the tablets have disintegrated. If 1 or 2 tablets fail to disintegrate completely, repeat the test on 12 additional tablets: not fewer than 16 of the total of 18 tablets tested disintegrate completely.

Hard Gelatin Capsules— Apply the test for Uncoated Tablets. Attach a removable wire cloth, which has a plain square weave with 1.8- to 2.2-mm mesh apertures and with a wire diameter of 0.60 to 0.655 mm, as described under Basket-Rack Assembly, to the surface of the upper plate of the basket-rack assembly. Observe the capsules within the time limit specified in the individual monograph: all of the capsules have disintegrated except for fragments from the capsule shell. If 1 or 2 capsules fail to disintegrate completely, repeat the test on 12 additional capsules: not fewer than 16 of the total of 18 capsules tested disintegrate completely.

Soft Gelatin Capsules— Proceed as directed under Hard Gelatin Capsules.♦

1 The use of automatic detection employing modified disks is permitted where the use of disks is specified or allowed. Such disks must comply with the requirements for density and dimension given in this chapter.

711 DISSOLUTION

This general chapter is harmonized with the corresponding texts of the European Pharmacopoeia and/or the Japanese Pharmacopoeia. These pharmacopeias have undertaken not to make any unilateral change to this harmonized chapter.

Portions of the present general chapter text that are national USP text, and therefore not part of the harmonized text, are marked with symbols (♦) to specify this fact.

This test is provided to determine compliance with the dissolution requirements ♦where stated in the individual monograph♦ for dosage forms administered orally. In this general chapter, a dosage unit is defined as 1 tablet or 1 capsule or the amount specified. ♦Of the types of apparatus described herein, use the one specified in the individual monograph. Where the label states that an article is enteric-coated, and where a dissolution or disintegration test that does not specifically state that it is to be applied to delayed-release articles is included in the individual monograph, the procedure and interpretation given for Delayed-Release Dosage Forms is applied unless otherwise specified in the individual monograph. For hard or soft gelatin capsules and gelatin-coated tablets that do not conform to the Dissolution specification, repeat the test as follows. Where water or a medium with a pH of less than 6.8 is specified as the Medium in the individual monograph, the same Medium specified may be used with the addition of purified pepsin that results in an activity of 750,000 Units or

less per 1000 mL. For media with a pH of 6.8 or greater, pancreatin can be added to produce not more than 1750 USP Units of protease activity per 1000 mL.

[USP Reference Standards](#) (11) — USP Chlorpheniramine Maleate Extended-Release Tablets RS. [USP Prednisone Tablets RS](#). [USP Salicylic Acid Tablets RS](#).

## APPARATUS

### Apparatus 1 (Basket Apparatus)

The assembly consists of the following: a vessel, which may be covered, made of glass or other inert, transparent material<sup>1</sup>; a motor; a metallic drive shaft; and a cylindrical basket. The vessel is partially immersed in a suitable water bath of any convenient size or heated by a suitable device such as a heating jacket. The water bath or heating device permits holding the temperature inside the vessel at  $37 \pm 0.5^\circ$  during the test and keeping the bath fluid in constant, smooth motion. No part of the assembly, including the environment in which the assembly is placed, contributes significant motion, agitation, or vibration beyond that due to the smoothly rotating stirring element. An apparatus that permits observation of the specimen and stirring element during the test is preferable. The vessel is cylindrical, with a hemispherical bottom and  $\blacklozenge$  with one of the following dimensions and capacities: for a nominal  $\blacklozenge$  capacity of 1 L, the height is 160 mm to 210 mm and its inside diameter is 98 mm to 106 mm;  $\blacklozenge$  for a nominal capacity of 2 L, the height is 280 mm to 300 mm and its inside diameter is 98 mm to 106 mm; and for a nominal capacity of 4 L, the height is 280 mm to 300 mm and its inside diameter is 145 mm to 155 mm  $\blacklozenge$ . Its sides are flanged at the top. A fitted cover may be used to retard evaporation.<sup>2</sup> The shaft is positioned so that its axis is not more than 2 mm at any point from the vertical axis of the vessel and rotates smoothly and without significant wobble that could affect the results. A speed-regulating device is used that allows the shaft rotation speed to be selected and maintained at the specified rate  $\blacklozenge$  given in the individual monograph,  $\blacklozenge$  within  $\pm 4\%$ .

Shaft and basket components of the stirring element are fabricated of stainless steel, type 316, or other inert material, to the specifications shown in [Figure 1](#). A basket having a gold coating of about 0.0001 inch (2.5  $\mu\text{m}$ ) thick may be used. A dosage unit is placed in a dry basket at the beginning of each test. The distance between the inside bottom of the vessel and the bottom of the basket is maintained at  $25 \pm 2$  mm during the test.

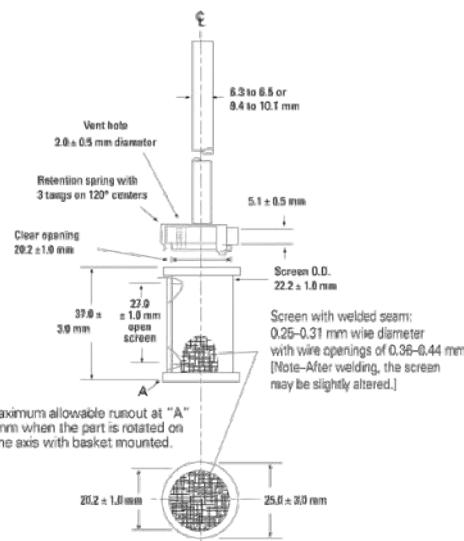

Figure 1. Basket Stirring Element

### Apparatus 2 (Paddle Apparatus)

Use the assembly from Apparatus 1, except that a paddle formed from a blade and a shaft is used as the stirring element. The shaft is positioned so that its axis is not more than 2 mm from the vertical axis of the vessel at any point and rotates smoothly without significant wobble that could affect the results. The vertical center line of the blade passes through the axis of the shaft so that the bottom of the blade is flush with the bottom of the shaft. The paddle conforms to the specifications shown in [Figure 2](#). The distance of  $25 \pm 2$  mm between the bottom of the blade and the inside bottom of the vessel is maintained during the test. The metallic or suitably inert, rigid blade and shaft comprise a single entity. A suitable two-part detachable design may be used provided the assembly remains firmly engaged during the test. The paddle blade and shaft may be coated with a suitable coating so as to make them inert. The dosage unit is allowed to sink to the bottom of the vessel before rotation of the blade is started. A small, loose piece of nonreactive material, such as not more than a few turns of wire helix, may be attached to dosage units that would otherwise float. An alternative sinker device is shown in [Figure 2a](#). Other validated sinker devices may be used.

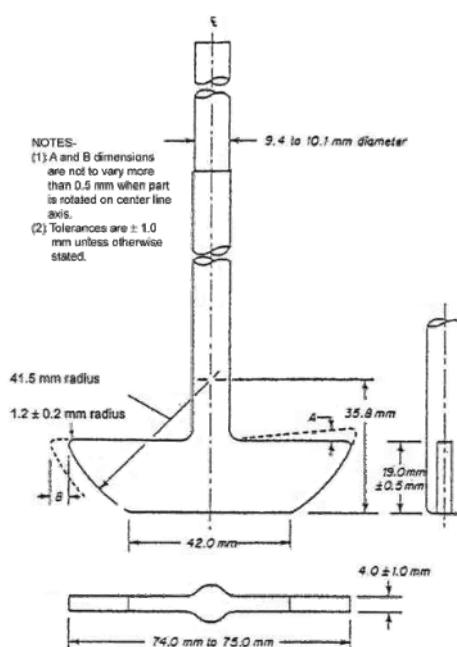

Figure 2. Paddle Stirring Element

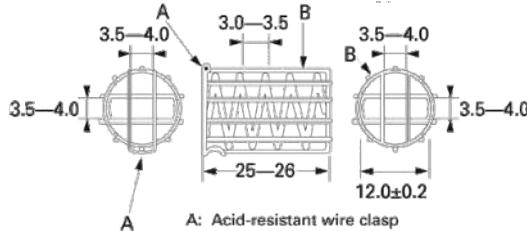

Figure 2a. Alternative sinker. All dimensions are expressed in mm.

Apparatus 3 (Reciprocating Cylinder)

not accepted by the Japanese pharmacopoeia

The assembly consists of a set of cylindrical, flat-bottomed glass vessels; a set of glass reciprocating cylinders; inert fittings (stainless steel type 316 or other suitable material), and screens that are made of suitable nonsorbing and nonreactive material and that are designed to fit the tops and bottoms of the reciprocating cylinders; and a motor and drive assembly to reciprocate the cylinders vertically inside the vessels and, if desired, index the reciprocating cylinders horizontally to a different row of vessels. The vessels are partially immersed in a suitable water bath of any convenient size that permits holding the temperature at  $37 \pm 0.5^\circ$  during the test. No part of the assembly, including the environment in which the assembly is placed, contributes significant motion, agitation, or vibration beyond that due to the smooth, vertically reciprocating cylinder. A device is used that allows the reciprocation rate to be

selected and maintained at the specified dip rate ♦given in the individual monograph♦ within  $\pm 5\%$ . An apparatus that permits observation of the specimens and reciprocating cylinders is preferable. The vessels are provided with an evaporation cap that remains in place for the duration of the test. The components conform to the dimensions shown in [Figure 3](#) unless otherwise specified ♦in the individual monograph♦.

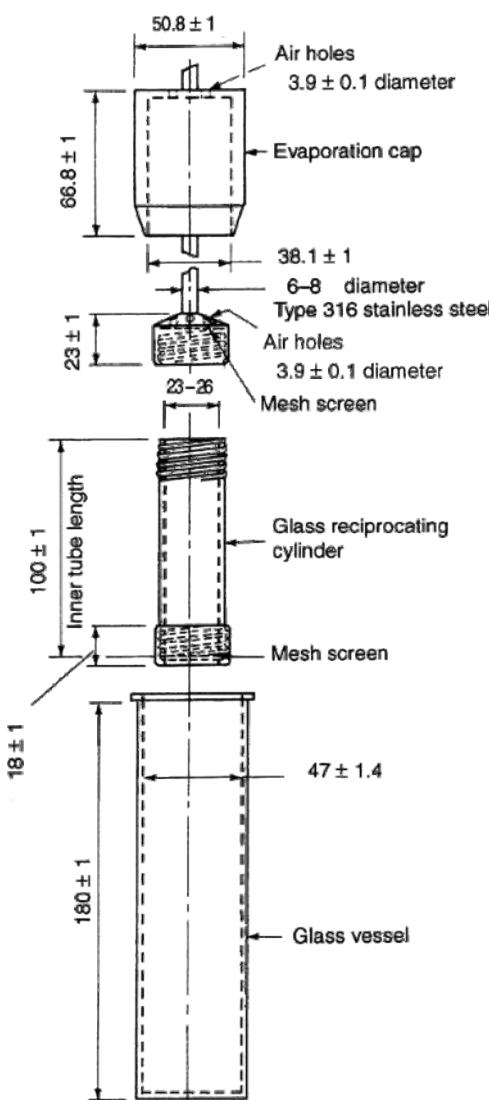

Figure 3. Apparatus 3 (reciprocating cylinder)

#### Apparatus 4 (Flow-Through Cell)

The assembly consists of a reservoir and a pump for the Dissolution Medium; a flow-through cell; and a water bath that maintains the Dissolution Medium at  $37 \pm 0.5^\circ$ . Use the specified cell size ♦ as given in the individual monograph ♦.

The pump forces the Dissolution Medium upwards through the flow-through cell. The pump has a delivery range between 240 and 960 mL per hour, with standard flow rates of 4, 8, and 16 mL per minute. It must deliver a constant flow ( $\pm 5\%$  of the nominal flow rate); the flow profile is sinusoidal with a pulsation of  $120 \pm 10$  pulses per minute.

The flow-through cell (see [Figures 4](#) and [5](#)), of transparent and inert material, is mounted vertically with a filter system (specified in the individual monograph) that prevents escape of undissolved particles from the top of the cell; standard cell diameters are 12 and 22.6 mm; the bottom cone is usually filled with small glass beads of about 1-mm diameter with one bead of about 5 mm positioned at the apex to protect the fluid entry tube; and a tablet holder (see [Figures 4](#) and [5](#)) is available for positioning of special dosage forms, for example, inlay tablets. The cell is immersed in a water bath, and the temperature is maintained at  $37 \pm 0.5^\circ$ .

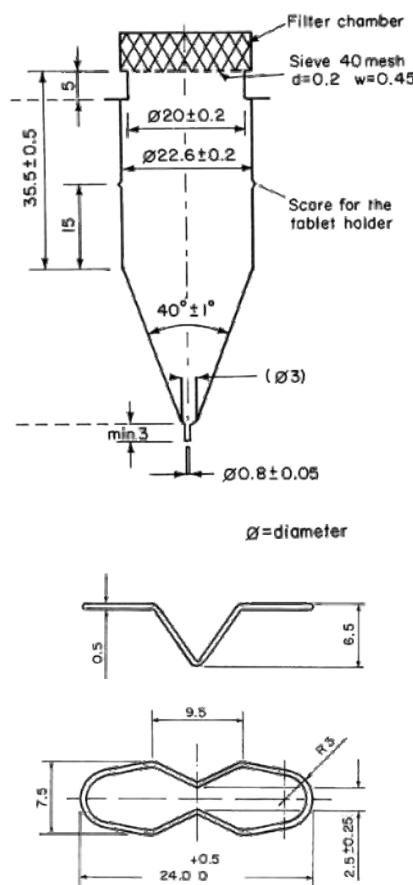

Figure 4. Large cell for tablets and capsules (top) Tablet holder for the large cell (bottom) (All measurements are expressed in mm unless noted otherwise.)

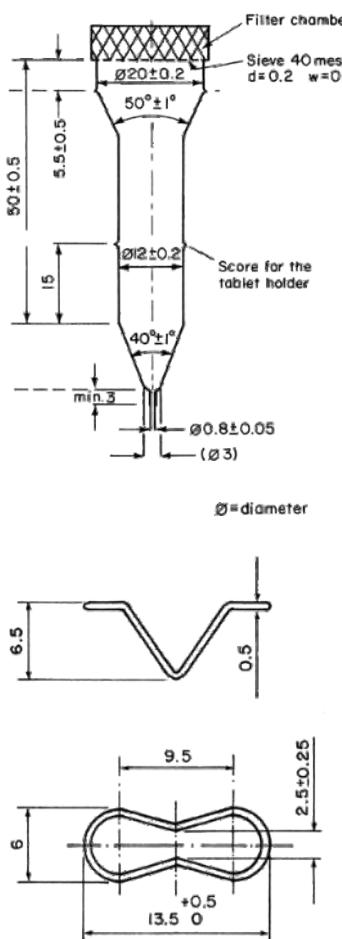

Figure 5. Small cell for tablets and capsules (top) Tablet holder for the small cell (bottom) (All measurements are expressed in mm unless noted otherwise.)

The apparatus uses a clamp mechanism and two O-rings to assemble the cell. The pump is separated from the dissolution unit in order to shield the latter against any vibrations originating from the pump. The position of the pump should not be on a level higher than the reservoir flasks. Tube connections are as short as possible. Use suitably inert tubing, such as polytef, with about 1.6-mm inner diameter and chemically inert flanged-end connections.

#### apparatus suitability

The determination of suitability of a test assembly to perform dissolution testing must include conformance to the dimensions and tolerances of the apparatus as given above. In addition, critical test parameters that have to be monitored periodically during use include volume and temperature of the Dissolution Medium, rotation speed (Apparatus 1 and Apparatus 2), dip rate (Apparatus 3), and flow rate of medium (Apparatus 4).

Determine the acceptable performance of the dissolution test assembly periodically. ♦The suitability for the individual apparatus is demonstrated by the Performance Verification Test.

Performance Verification Test, Apparatus 1 and 2— Individually test 1 tablet of the USP Prednisone Tablets RS and 1 tablet of USP Salicylic Acid Tablets RS, according to the operating conditions specified. The apparatus is suitable if the results obtained are within the acceptable range stated in the certificate for that Reference Standard tablet in the apparatus tested.

Performance Verification Test, Apparatus 3— Individually test 1 tablet of the USP Chlorpheniramine Maleate Extended-Release Tablets RS according to the operating conditions specified. The apparatus is suitable if the results obtained are within the acceptable range stated in the certificate.

Performance Verification Test, Apparatus 4— [To come.]♦

#### PROCEDURE

##### Apparatus 1 and Apparatus 2

##### immediate-release dosage forms

Place the stated volume of the Dissolution Medium ( $\pm 1\%$ ) in the vessel of the specified apparatus ♦given in the individual monograph♦, assemble the apparatus, equilibrate the Dissolution Medium to  $37 \pm 0.5^\circ$ , and remove the thermometer. Place 1 dosage unit in the apparatus, taking care to exclude air bubbles from the surface of the dosage unit, and immediately operate the apparatus at the specified rate ♦given in the individual monograph♦. Within the time interval specified, or at each of the times stated, withdraw a specimen from a zone midway between the surface of the Dissolution Medium and the top of the rotating basket or blade, not less than 1 cm from the vessel wall. [note—Where multiple sampling times are specified, replace the aliquots withdrawn for analysis with equal volumes of fresh Dissolution Medium at  $37^\circ$  or, where it can be shown that replacement of the medium is not necessary, correct for the volume change in the calculation. Keep the vessel covered for the duration of the test, and verify the temperature of the mixture under test at suitable times.] Perform the analysis ♦as directed in the individual monograph♦ using a suitable assay method.<sup>3</sup> Repeat the test with additional dosage form units.

If automated equipment is used for sampling or the apparatus is otherwise modified, verification that the modified apparatus will produce results equivalent to those obtained with the standard apparatus described in this general chapter is necessary.

Dissolution Medium— A suitable dissolution medium is used. Use the solvent specified ♦in the individual monograph♦. The volume specified refers to measurements made between  $20^\circ$  and  $25^\circ$ . If the Dissolution Medium is a buffered solution, adjust the solution so that its pH is within 0.05 unit of the specified pH ♦given in the individual monograph♦. [note—Dissolved gases can cause bubbles to form, which may change the results of the test. If dissolved gases influence the dissolution results, dissolved gases should be removed prior to

testing.<sup>4</sup>

Time— Where a single time specification is given, the test may be concluded in a shorter period if the requirement for minimum amount dissolved is met. Specimens are to be withdrawn only at the stated times within a tolerance of  $\pm 2\%$ .

◆ Procedure for a Pooled Sample for Immediate-Release Dosage Forms —Use this procedure where Procedure for a Pooled Sample is specified in the individual monograph. Proceed as directed in Procedure for Apparatus 1 and Apparatus 2 in Immediate-Release Dosage Forms. Combine equal volumes of the filtered solutions of the six or twelve individual specimens withdrawn, and use the pooled sample as the test specimen. Determine the average amount of the active ingredient dissolved in the pooled sample.◆

extended-release dosage forms

Proceed as directed for Immediate-Release Dosage Forms.

Dissolution Medium— Proceed as directed for Immediate-Release Dosage Forms.

Time— The test-time points, generally three, are expressed in hours.

delayed-release dosage forms

not accepted by the Japanese pharmacopoeia

Use Method A or Method B and the apparatus specified ◆ in the individual monograph◆. All test times stated are to be observed within a tolerance of  $\pm 2\%$ , unless otherwise specified.

Method A—

Procedure ◆(unless otherwise directed in the individual monograph)◆—

acid stage— Place 750 mL of 0.1 N hydrochloric acid in the vessel, and assemble the apparatus. Allow the medium to equilibrate to a temperature of  $37 \pm 0.5^\circ$ . Place 1 dosage unit in the apparatus, cover the vessel, and operate the apparatus at the specified rate ◆ given in the monograph◆.

After 2 hours of operation in 0.1 N hydrochloric acid, withdraw an aliquot of the fluid, and proceed immediately as directed under Buffer Stage.

Perform an analysis of the aliquot using a suitable assay method. ◆ The procedure is specified in the individual monograph.◆

buffer stage— [note—Complete the operations of adding the buffer and adjusting the pH within 5 minutes.]

With the apparatus operating at the rate specified ◆ in the monograph◆, add to the fluid in the vessel 250 mL of 0.20 M tribasic sodium phosphate that has been equilibrated to  $37 \pm 0.5^\circ$ . Adjust, if necessary, with 2 N hydrochloric acid or 2 N sodium hydroxide to a pH of  $6.8 \pm 0.05$ . Continue to operate the apparatus for 45 minutes, or for the specified time ◆ given in the individual monograph◆. At the end of the time period, withdraw an aliquot of the fluid, and perform the analysis using a suitable assay method. ◆ The procedure is specified in the individual monograph. The test may be concluded in a shorter time period than that specified for the Buffer Stage if the requirement for the minimum amount dissolved is met at an

earlier time.◆

Method B—

Procedure ◆(unless otherwise directed in the individual monograph)◆—

acid stage— Place 1000 mL of 0.1 N hydrochloric acid in the vessel, and assemble the apparatus. Allow the medium to equilibrate to a temperature of  $37 \pm 0.5^\circ$ . Place 1 dosage unit in the apparatus, cover the vessel, and operate the apparatus at the rate specified ◆ in the monograph◆. After 2 hours of operation in 0.1 N hydrochloric acid, withdraw an aliquot of the fluid, and proceed immediately as directed under Buffer Stage.

Perform an analysis of the aliquot using a suitable assay method. ◆ The procedure is specified in the individual monograph.◆

buffer stage— [note—For this stage of the procedure, use buffer that previously has been equilibrated to a temperature of  $37 \pm 0.5^\circ$ .] Drain the acid from the vessel, and add to the vessel 1000 mL of pH 6.8 phosphate buffer, prepared by mixing 0.1 N hydrochloric acid with 0.20 M tribasic sodium phosphate (3:1) and adjusting, if necessary, with 2 N hydrochloric acid or 2 N sodium hydroxide to a pH of  $6.8 \pm 0.05$ . [note—This may also be accomplished by removing from the apparatus the vessel containing the acid and replacing it with another vessel containing the buffer and transferring the dosage unit to the vessel containing the buffer.]

Continue to operate the apparatus for 45 minutes, or for the specified time ◆ given in the individual monograph◆. At the end of the time period, withdraw an aliquot of the fluid, and perform the analysis using a suitable assay method. ◆ The procedure is specified in the individual monograph. The test may be concluded in a shorter time period than that specified for the Buffer Stage if the requirement for minimum amount dissolved is met at an earlier time.◆

Apparatus 3 (Reciprocating Cylinder)

not accepted by the Japanese pharmacopoeia

immediate-release dosage forms

Place the stated volume of the Dissolution Medium in each vessel of the apparatus, assemble the apparatus, equilibrate the Dissolution Medium to  $37 \pm 0.5^\circ$ , and remove the thermometer. Place 1 dosage-form unit in each of the six reciprocating cylinders, taking care to exclude air bubbles from the surface of each dosage unit, and immediately operate the apparatus as specified ◆ in the individual monograph◆. During the upward and downward stroke, the reciprocating cylinder moves through a total distance of 9.9 to 10.1 cm. Within the time interval specified, or at each of the times stated, raise the reciprocating cylinders and withdraw a portion of the solution under test from a zone midway between the surface of the Dissolution Medium and the bottom of each vessel. Perform the analysis as directed ◆ in the individual monograph◆. If necessary, repeat the test with additional dosage-form units.

Dissolution Medium —Proceed as directed for Immediate-Release Dosage Forms under Apparatus 1 and Apparatus 2.

Time —Proceed as directed for Immediate-Release Dosage Forms under Apparatus 1 and Apparatus 2.

extended-release dosage forms

Proceed as directed for Immediate-Release Dosage Forms under Apparatus 3.

Dissolution Medium —Proceed as directed for Extended-Release Dosage Forms under Apparatus 1 and Apparatus 2.

Time —Proceed as directed for Extended-Release Dosage Forms under Apparatus 1 and Apparatus 2.

delayed-release dosage forms

Proceed as described for Delayed-Release Dosage Forms, Method B under Apparatus 1 and Apparatus 2 using one row of vessels for the acid stage media and the following row of vessels for the buffer stage media and using the volume of medium specified (usually 300 mL).

Time —Proceed as directed for Immediate-Release Dosage Forms under Apparatus 1 and Apparatus 2.

Apparatus 4 (Flow-Through Cell)

immediate-release dosage forms

Place the glass beads into the cell specified ◆ in the monograph◆. Place 1 dosage unit on top of the beads or, if specified ◆ in the monograph◆, on a wire carrier. Assemble the filter head, and fix the parts together by means of a suitable clamping device. Introduce by the pump the Dissolution Medium warmed to  $37 \pm 0.5^\circ$  through the bottom of the cell to obtain the

ow rate specified ♦ in the individual monograph♦ and measured with an accuracy of 5%. Collect the eluate by fractions at each of the times stated. Perform the analysis as directed in the individual monograph♦. Repeat the test with additional dosage-form units.

Dissolution Medium — Proceed as directed for Immediate-Release Dosage Forms under Apparatus 1 and Apparatus 2.

Time — Proceed as directed for Immediate-Release Dosage Forms under Apparatus 1 and Apparatus 2.  
extended-release dosage forms

Proceed as directed for Immediate-Release Dosage Forms under Apparatus 4.

Dissolution Medium — Proceed as directed for Immediate-Release Dosage Forms under Apparatus 4.

Time — Proceed as directed for Immediate-Release Dosage Forms under Apparatus 4.  
delayed-release dosage forms

Proceed as directed for Delayed-Release Dosage Forms under Apparatus 1 and Apparatus 2, using the specified media.

Time — Proceed as directed for Delayed-Release Dosage Forms under Apparatus 1 and Apparatus 2.

#### INTERPRETATION

##### Immediate-Release Dosage Forms

Unless otherwise specified ♦ in the individual monograph♦, the requirements are met if the quantities of active ingredient dissolved from the dosage units tested conform to Acceptance Table 1. Continue testing through the three stages unless the results conform at either S1 or S2. The quantity, Q, is the amount of dissolved active ingredient ♦ specified in the individual monograph♦, expressed as a percentage of the labeled content of the dosage unit; the 5%, 15%, and 25% values in [Acceptance Table 1](#) are percentages of the labeled content so that these values and Q are in the same terms.

Acceptance Table 1

Stage	Number Tested	Acceptance Criteria
S1	6	Each unit is not less than Q + 5%.
S2	6	Average of 12 units (S1 + S2) is equal to or greater than Q, and no unit is less than Q - 15%.
S3	12	Average of 24 units (S1 + S2 + S3) is equal to or greater than Q, not more than 2 units are less than Q - 15%, and no unit is less than Q - 25%.

♦ Immediate-Release Dosage Forms Pooled Sample — Unless otherwise specified in the individual monograph, the requirements are met if the quantities of active ingredient dissolved from the pooled sample conform to the accompanying Acceptance Table for a Pooled Sample. Continue testing through the three stages unless the results conform at either S1 or S2.

The quantity, Q, is the amount of dissolved active ingredient specified in the individual monograph, expressed as a percentage of the labeled content.

Acceptance Table for a Pooled Sample

Stage	Number Tested	Acceptance Criteria
S1	6	Average amount dissolved is not less than Q + 10%.
S2	6	Average amount dissolved (S1 + S2) is equal to or greater than Q + 5%.
S3	12	Average amount dissolved (S1 + S2 + S3) is equal to or greater than Q.

♦

##### Extended-Release Dosage Forms

Unless otherwise specified ♦ in the individual monograph♦, the requirements are met if the quantities of active ingredient dissolved from the dosage units tested conform to [Acceptance Table 2](#). Continue testing through the three levels unless the results conform at either L1 or L2. Limits on the amounts of active ingredient dissolved are expressed in terms of the percentage of labeled content. The limits embrace each value of Qi, the amount dissolved at each specified fractional dosing interval. Where more than one range is specified

♦ in the individual monograph♦, the acceptance criteria apply individually to each range.

Acceptance Table 2

Level	Number Tested	Criteria
L1	6	No individual value lies outside each of the stated ranges and no individual value is less than the stated amount at the final test time.
L2	6	The average value of the 12 units (L1 + L2) lies within each of the stated ranges and is not less than the stated amount at the final test time; none is more than 10% of labeled content outside each of the stated ranges; and none is more than 10% of labeled content below the stated amount at the final test time.
L3	12	The average value of the 24 units (L1 + L2 + L3) lies within each of the stated ranges, and is not less than the stated amount at the final test time; not more than 2 of the 24 units are more than 10% of labeled content outside each of the stated ranges; not more than 2 of the 24 units are more than 10% of labeled content below the stated amount at the final test time; and none of the units is more than 20% of labeled content outside each of the stated ranges or more than 20% of labeled content below the stated amount at the final test time.

##### Delayed-Release Dosage Forms

not accepted by the Japanese pharmacopoeia.

Acid Stage — Unless otherwise specified ♦ in the individual monograph♦, the requirements of this portion of the test are met if the quantities, based on the percentage of the labeled content, of active ingredient dissolved from the units tested conform to [Acceptance Table 3](#). Continue testing through all levels unless the results of both acid and buffer stages conform at an earlier level.

Acceptance Table 3

Level	Number Tested	Criteria
A1	6	No individual value exceeds 10% dissolved.
A2	6	Average of the 12 units (A1 + A2) is not more than 10% dissolved, and no individual unit is greater than 25% dissolved.
A3	12	Average of the 24 units (A1 + A2 + A3) is not more than 10% dissolved, and no individual unit is greater than 25% dissolved.

Buffer Stage — Unless otherwise specified ♦ in the individual monograph♦, the requirements are met if the quantities of active ingredient dissolved from the units tested conform to [Acceptance Table 4](#). Continue testing through the three levels unless the results of both stages conform at an earlier level. The value of Q in [Acceptance Table 4](#) is 75% dissolved unless otherwise specified ♦ in the individual monograph♦. The quantity, Q, ♦ specified in the individual monograph♦ is the total amount of active ingredient dissolved in both the

and Buffer Stages, expressed as a percentage of the labeled content. The 5%, 15%, and 25% values in [Acceptance Table 4](#) are percentages of the labeled content so that the values and Q are in the same terms.

Acceptance Table 4

Level	Number Tested	Criteria
B1	6	Each unit is not less than Q + 5%.
B2	6	Average of 12 units (B1 + B2) is equal to or greater than Q, and no unit is less than Q - 15%.
B3	12	Average of 24 units (B1 + B2 + B3) is equal to or greater than Q, not more than 2 units are less than Q - 15%, and no unit is less than Q - 25%.

1 The materials should not sorb, react, or interfere with the specimen being tested.

2 If a cover is used, it provides sufficient openings to allow ready insertion of the thermometer and withdrawal of specimens.

3 Test specimens are filtered immediately upon sampling unless filtration is demonstrated to be unnecessary. Use an inert filter that does not cause adsorption of the active ingredient or contain extractable substances that would interfere with the analysis.

4 One method of deaeration is as follows: Heat the medium, while stirring gently, to about 41°, immediately filter under vacuum using a filter having a porosity of 0.45 µm or less, with vigorous stirring, and continue stirring under vacuum for about 5 minutes. Other validated deaeration techniques for removal of dissolved gases may be used.

Auxiliary Information— Please [check for your question in the FAQs](#) before contacting USP.

## 721 DISTILLING RANGE

To determine the range of temperatures within which an official liquid distills, or the percentage of the material that distills between two specified temperatures, use Method I or Method II as directed in the individual monograph. The lower limit of the range is the temperature indicated by the thermometer when the first drop of condensate leaves the tip of the condenser, and the upper limit is the Dry Point, i.e., the temperature at which the last drop of liquid evaporates from the lowest point in the distillation flask, without regard to any liquid remaining on the side of the flask, or the temperature observed when the proportion specified in the individual monograph has been collected.

note—Cool all liquids that distill below 80° to between 10° and 15° before measuring the sample to be distilled.

### Method I

Apparatus— Use apparatus similar to that specified for Method II, except that the distilling flask is of 50- to 60-mL capacity, and the neck of the flask is 10 to 12 cm long and 14 to 16 mm in internal diameter. The perforation in the upper insulating board, if one is used, should be such that when the flask is set into it, the portion of the flask below the upper surface of the insulating material has a capacity of 3 to 4 mL.

Procedure— Proceed as directed for Method II, but place in the flask only 25 mL of the liquid to be tested.

### Method II

Apparatus— Use an apparatus consisting of the following parts:

Distilling Flask— A round-bottom distilling flask, of heat-resistant glass, of 200-mL capacity, and having a total length of 17 to 19 cm, and an inside neck diameter of 20 to 22 mm. Attached about midway on the neck, approximately 12 cm from the bottom of the flask, is a side-arm 10 to 12 cm long and 5 mm in internal diameter, which forms an angle of 70° to 75° with the lower portion of the neck.

Condenser— A straight glass condenser 55 to 60 cm in length with a water jacket about 40 cm in length, or a condenser of other design having equivalent condensing capacity. The lower end of the condenser may be bent to provide a delivery tube, or it may be connected to a bent adapter that serves as a delivery tube.

Insulating Boards— Two pieces of insulating board, 5 to 7 mm thick and 14 to 16 cm square, suitable for confining the heat to the lower part of the flask. Each board has a hole in its center, and the two boards differ only with respect to the diameter of the hole, i.e., the diameters are 4 cm and 10 cm, respectively. In use, the boards are placed one upon the other, and rest on a tripod or other suitable support, with the board having the larger hole on top.

Receiver— A 100-mL cylinder graduated in 1-mL subdivisions.

Thermometer— In order to avoid the necessity for an emergent stem correction, an accurately standardized, partial-immersion thermometer having the smallest practical subdivisions (not greater than 0.2°) is recommended. Suitable thermometers are available as the ASTM E-1 series 37C through 41C, and 102C through 107C (see [Thermometers](#) 21). When placed in position, the stem is located in the center of the neck, and the top of the contraction chamber (or bulb, if 37C or 38C is used) is level with the bottom of the outlet to the side-arm.

Heat Source— A small Bunsen burner or an electric heater or mantle capable of adjustment comparable to that possible with a Bunsen burner.

Procedure— Assemble the apparatus, and place in the flask 100 mL of the liquid to be tested, taking care not to allow any of the liquid to enter the side-arm. Insert the thermometer, shield the entire burner and flask assembly from external air currents, and apply heat, regulating it so that between 5 and 10 minutes elapse before the first drop of distillate falls from the condenser. Continue the distillation at a rate of 4 to 5 mL of distillate per minute, collecting the distillate in the receiver. Note the temperature when the first drop of distillate falls from the condenser, and again when the last drop of liquid evaporates from the bottom of the flask or when the specified percentage has distilled over. Unless otherwise specified in the individual monograph, apply when necessary the emergent stem correction and report the temperatures adjusting the barometric pressure by the following formula:

$$t = t_0 + [(t_0 - 10 + 0.033)(760 - p)]$$

in which t is the corrected boiling temperature, in Celsius scale;  $t_0$  is the measured boiling temperature, in Celsius scale; and p is the barometric pressure at the time of measurement, in mm Hg.

## 724 DRUG RELEASE

This test is provided to determine compliance with drug-release requirements where specified in individual monographs. Use the apparatus specified in the individual monograph. Replace the aliquots withdrawn for analysis with equal volumes of fresh Dissolution Medium at the temperature specified in the monograph or, where it can be shown that replacement of the medium is not necessary, correct for the volume change in the calculation. Keep the vessel covered for the duration of the test, and verify the temperature of the mixture under test at suitable times.

## TRANSDERMAL DELIVERY SYSTEMS—GENERAL DRUG RELEASE STANDARDS

## Apparatus 5 (Paddle over Disk)

Apparatus— Use the paddle and vessel assembly from Apparatus 2 as described under [Dissolution 711](#), with the addition of a stainless steel disk assembly<sup>1</sup> designed for holding the transdermal system at the bottom of the vessel. Other appropriate devices may be used, provided they do not sorb, react with, or interfere with the specimen being tested<sup>2</sup>. The temperature is maintained at  $32 \pm 0.5^\circ$ . A distance of  $25 \pm 2$  mm between the paddle blade and the surface of the disk assembly is maintained during the test. The vessel may be covered during the test to minimize evaporation. The disk assembly for holding the transdermal system is designed to minimize any “dead” volume between the disk assembly and the bottom of the vessel. The disk assembly holds the system flat and is positioned such that the release surface is parallel with the bottom of the paddle blade (see [Figure 1](#)).

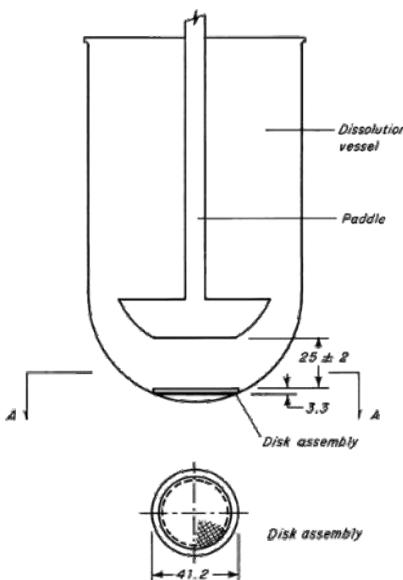

Fig. 1. Paddle Over Disk.(All measurements are expressed in mm unless noted otherwise.)

Apparatus Suitability Test and Dissolution Medium— Proceed as directed for Apparatus 2 under [Dissolution 711](#).

Procedure— Place the stated volume of the Dissolution Medium in the vessel, assemble the apparatus without the disk assembly, and equilibrate the medium to  $32 \pm 0.5^\circ$ . Apply the transdermal system to the disk assembly, assuring that the release surface of the system is as flat as possible. The system may be attached to the disk by applying a suitable adhesive<sup>3</sup> to the disk assembly. Dry for 1 minute. Press the system, release surface side up, onto the adhesive-coated side of the disk assembly. If a membrane<sup>4</sup> is used to support the system, it is applied so that no air bubbles occur between the membrane and the release surface. Place the disk assembly flat at the bottom of the vessel with the release surface facing up and parallel to the edge of the paddle blade and surface of the Dissolution Medium. The bottom edge of the paddle is  $25 \pm 2$  mm from the surface of the disk assembly.

Immediately operate the apparatus at the rate specified in the monograph. At each sampling time interval, withdraw a specimen from a zone midway between the surface of the Dissolution Medium and the top of the blade, not less than 1 cm from the vessel wall. Perform the analysis on each sampled aliquot as directed in the individual monograph, correcting for any volume losses, as necessary. Repeat the test with additional transdermal systems.

Time— The test time points, generally three, are expressed in hours. Specimens are to be withdrawn within a tolerance of  $\pm 15$  minutes or  $\pm 2\%$  of the stated time, the tolerance that results in the narrowest time interval being selected.

Interpretation— Unless otherwise specified in the individual monograph, the requirements are met if the quantities of active ingredient released from the system conform to [Acceptance Table 1](#) for transdermal drug delivery systems. Continue testing through the three levels unless the results conform at either L1 or L2.

Acceptance Table 1

Level	Number Tested	Criteria
L1	6	No individual value lies outside the stated range.
L2	6	The average value of the 12 units (L1 + L2) lies within the stated range. No individual value is outside the stated range by more than 10% of the average of the stated range.
L3	12	The average value of the 24 units (L1 + L2 + L3) lies within the stated range. Not more than 2 of the 24 units are outside the stated range by more than 10% of the average of the stated range; and none of the units is outside the stated range by more than 20% of the average of the stated range.

## Apparatus 6 (Cylinder)

Apparatus— Use the vessel assembly from Apparatus 1 as described under [Dissolution 711](#), except to replace the basket and shaft with a stainless steel cylinder stirring element and to maintain the temperature at  $32 \pm 0.5^\circ$  during the test. The shaft and cylinder components of the stirring element are fabricated of stainless steel to the specifications shown in [Figure 2](#). The dosage unit is placed on the cylinder at the beginning of each test. The distance between the inside bottom of the vessel and the cylinder is maintained at  $25 \pm 2$  mm during the test.

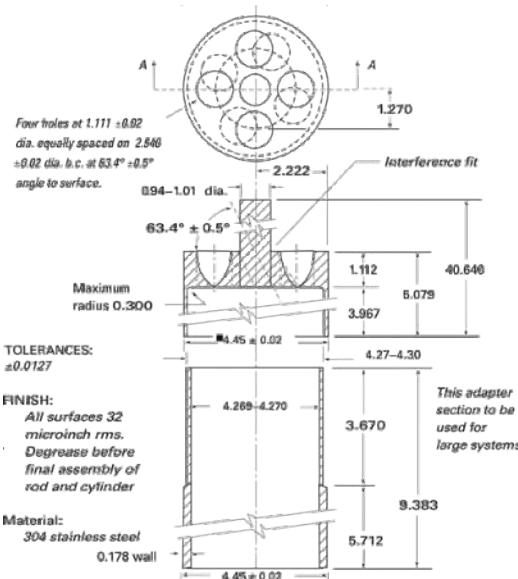

Fig. 2. Cylinder Stirring Element.<sup>5</sup> (All measurements are expressed in cm unless noted otherwise.)

Dissolution Medium— Use the medium specified in the individual monograph (see [Dissolution](#) (711)).

Procedure— Place the stated volume of the Dissolution Medium in the vessel of the apparatus specified in the individual monograph, assemble the apparatus, and equilibrate the Dissolution Medium to  $32 \pm 0.5^{\circ}\text{C}$ . Unless otherwise directed in the individual monograph, prepare the test system prior to test as follows. Remove the protective liner from the system, and place the adhesive side on a piece of Cuprophan<sup>4</sup> that is not less than 1 cm larger on all sides than the system. Place the system, Cuprophan covered side down, on a clean surface, and apply a suitable adhesive<sup>3</sup> to the exposed Cuprophan borders. If necessary, apply additional adhesive to the back of the system. Dry for 1 minute. Carefully apply the adhesive-coated side of the system to the exterior of the cylinder such that the long axis of the system fits around the circumference of the cylinder. Press the Cuprophan covering to remove trapped air bubbles. Place the cylinder in the apparatus, and immediately rotate at the rate specified in the individual monograph. Within the time interval specified, or at each of the times stated, withdraw a quantity of Dissolution Medium for analysis from a zone midway between the surface of the Dissolution Medium and the top of the rotating cylinder, not less than 1 cm from the vessel wall. Perform the analysis as directed in the individual monograph, correcting for any volume losses as necessary. Repeat the test with additional transdermal drug delivery systems.

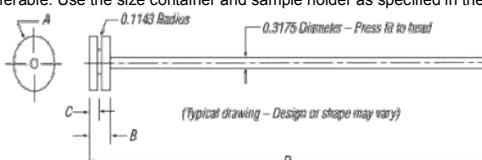

Time— Proceed as directed under Apparatus 5.

Interpretation— Unless otherwise specified in the individual monograph, the requirements are met if the quantities of active ingredient released from the system conform to [Acceptance Table 1](#) for transdermal drug delivery systems. Continue testing through the three levels unless the results conform at either L1 or L2.

#### Apparatus 7 (Reciprocating Holder)

note—This apparatus may also be specified for use with a variety of dosage forms.

Apparatus— The assembly consists of a set of volumetrically calibrated or tared solution containers made of glass or other suitable inert material<sup>6</sup>, a motor and drive assembly to reciprocate the system vertically and to index the system horizontally to a different row of vessels automatically if desired, and a set of suitable sample holders (see [Figure 3](#)<sup>7</sup> and Figures 4a–4d). The solution containers are partially immersed in a suitable water bath of any convenient size that permits maintaining the temperature, T, inside the containers at  $32 \pm 0.5^{\circ}\text{C}$  or within the allowable range, as specified in the individual monograph, during the test. No part of the assembly, including the environment in which the assembly is placed, contributes significant motion, agitation, or vibration beyond that due to the smooth, vertically reciprocating sample holder. Apparatus that permits observation of the system and holder during the test is preferable. Use the size container and sample holder as specified in the individual monograph.

Dimensions are in centimeters

System <sup>a</sup>	HEAD			ROD		O-RING (not shown)
	A (Diameter)	B	C	Material <sup>b</sup>	D	
1.6cm <sup>2</sup>	1.428	0.9525	0.4750	SS/VT	30.48	SS/P
2.5cm <sup>2</sup>	1.778	0.9525	0.4750	SS/VT	30.48	SS/P
5cm <sup>2</sup>	2.0824	0.7620	0.3810	SS/VT	8.890	SS/P
7cm <sup>2</sup>	3.1750	0.7620	0.3810	SS/VT	30.48	SS/P
10cm <sup>2</sup>	5.0292	0.6350	0.3505	SS/VT	31.01	SS/P

<sup>a</sup> Typical system sizes.

<sup>b</sup> SS/VT—Either stainless steel or virgin Teflon.

<sup>c</sup> SS/P—Either stainless steel or Plexiglas.

Fig. 3. Reciprocating Disk Sample Holder.7

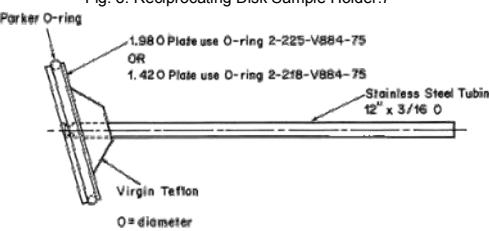

Fig. 4a. Transdermal System Holder—Angled Disk.

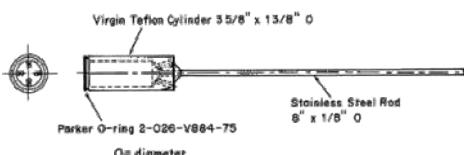

Fig. 4b. Transdermal System Holder—Cylinder.

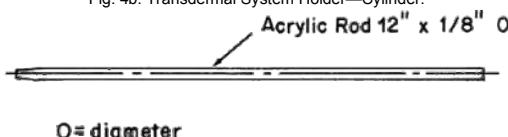

Fig. 4c. Oral Extended-Release Tablet Holder—Rod, Pointed for Gluing.

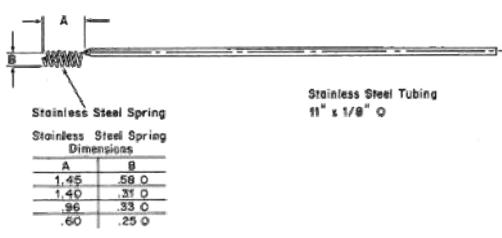

Fig. 4d. Oral Extended-Release Tablet Holder—Spring Holder.

Dissolution Medium— Use the Dissolution Medium specified in the individual monograph (see [Dissolution \(711\)](#)).

Sample Preparation A (Coated tablet drug delivery system)— Attach each system to be tested to a suitable sample holder (e.g., by gluing system edge with 2-cyano acrylate glue onto the end of a plastic rod or by placing the system into a small nylon net bag at the end of a plastic rod or within a metal coil attached to a metal rod).

Sample Preparation B (Transdermal drug delivery system)— Press the system onto a dry, unused piece of Cuprophan<sup>4</sup>, nylon netting, or equivalent with the adhesive side against the selected substrate, taking care to eliminate air bubbles between the substrate and the release surface. Attach the system to a suitable sized sample holder with a suitable O-ring such that the back of the system is adjacent to and centered on the bottom of the disk-shaped sample holder or centered around the circumference of the cylindrical-shaped sample holder. Trim the excess substrate with a sharp blade.

Sample Preparation C (Other drug delivery systems)— Attach each system to be tested to a suitable holder as described in the individual monograph.

Procedure— Suspend each sample holder from a vertically reciprocating shaker such that each system is continuously immersed in an accurately measured volume of Dissolution Medium within a calibrated container pre-equilibrated to temperature, T. Reciprocate at a frequency of about 30 cycles per minute with an amplitude of about 2 cm, or as specified in the individual monograph, for the specified time in the medium specified for each time point. Remove the solution containers from the bath, cool to room temperature, and add sufficient solution (i.e., water in most cases) to correct for evaporative losses. Perform the analysis as directed in the individual monograph. Repeat the test with additional drug delivery systems as required in the individual monograph.

Interpretation— Unless otherwise specified in the individual monograph, the requirements are met if the quantities of the active ingredients released from the system conform to Acceptance Table 2 under [Dissolution \(711\)](#) for coated tablet drug delivery systems, to [Acceptance Table 1](#) for transdermal drug delivery systems, or as specified in the individual monograph. Continue testing through the three levels unless the results conform at either L1 or L2.

1 Disk assembly (stainless support disk) may be obtained from Millipore Corp., Ashley Rd., Bedford, MA 01730.

2 A suitable device is the watchglass-patch-polytef mesh sandwich assembly available as the Transdermal SandwichTM from Hanson Research Corp., 9810 Variel Ave., Chatsworth, CA 91311.

3 Use Dow Corning, MD7-4502 Silicone Adhesive 65% in ethyl acetate, or the equivalent.

4 Use Cuprophan, Type 150 pm,  $11 \pm 0.5\text{-}\mu\text{m}$  thick, an inert, porous cellulosic material, which is available from Medicell International Ltd., 239 Liverpool Road, London NI 1LX, England.

5 The cylinder stirring element is available from Accurate Tool, Inc., 25 Diaz St., Stamford, CT 06907, or from VanKel Technology Group, 13000 Weston Parkway, Cary, NC 27513.

6 The materials should not sorb, react with, or interfere with the specimen being tested.

7 The reciprocating disk sample holder may be purchased from ALZA Corp., 1900 Charleston Road, P.O. Box 7210, Mt. View, CA 94039-7210 or VanKel Technology Group.

### 726 ELECTROPHORESIS

Electrophoresis refers to the migration of electrically charged proteins, colloids, molecules, or other particles when dissolved or suspended in an electrolyte through which an electric current is passed.

Based upon the type of apparatus used, electrophoretic methods may be divided into two categories, one called free solution or moving boundary electrophoresis and the other called zone electrophoresis.

In the free solution method, a buffered solution of proteins in a U-shaped cell is subjected to an electric current which causes the proteins to form a series of layers in order of decreasing mobility, which are separated by boundaries. Only a part of the fastest moving protein is physically separated from the other proteins, but examination of the moving boundaries using a schlieren optical system provides data for calculation of mobilities and information on the qualitative and quantitative composition of the protein mixture.

In zone electrophoresis, the sample is introduced as a narrow zone or spot in a column, slab, or film of buffer. Migration of the components as narrow zones permits their complete separation. Remixing of the separated zones by thermal convection is prevented by stabilizing the electrolyte in a porous matrix such as a powdered solid, or a fibrous material such as paper, or a gel such as starch, agar, or polyacrylamide.

Various methods of zone electrophoresis are widely employed. Gel electrophoresis, particularly the variant called disk electrophoresis, is especially useful for protein separation because of its high resolving power.

Gel electrophoresis, which is employed by the compendium, is discussed in more detail following the presentation of some theoretical principles and methodological practices, which are shared in varying degrees by all electrophoretic methods.

The electrophoretic migration observed for particles of a particular substance depends on characteristics of the particle, primarily its electrical charge, its size or molecular weight, and its shape, as well as characteristics and operating parameters of the system. These latter include the pH, ionic strength, viscosity and temperature of the electrolyte, density or cross-linking of any stabilizing matrix such as gel, and the voltage gradient employed.

**Effect of Charge, Particle Size, Electrolyte Viscosity, and Voltage Gradient**— Electrically charged particles migrate toward the electrode of opposite charge, and molecules with both positive and negative charges move in a direction dependent on the net charge. The rate of migration is directly related to the magnitude of the net charge on the particle and is inversely related to the size of the particle, which in turn is directly related to its molecular weight.

Very large spherical particles, for which Stokes' law is valid, exhibit an electrophoretic mobility,  $u_0$ , which is inversely related to the first power of the radius as depicted in the equation:

$$u_0 = \frac{v}{E} = \frac{Q}{6\pi r \eta}$$

where  $v$  is the velocity of the particle,  $E$  is the voltage gradient imposed on the electrolyte,  $Q$  is the charge on the particle,  $r$  is the particle radius, and  $\eta$  is the viscosity of the electrolyte. This idealized expression is strictly valid only at infinite dilution and in the absence of a stabilizing matrix such as paper or a gel.

Ions, and peptides up to molecular weights of at least 5000, particularly in the presence of stabilizing media, do not obey Stokes' law, and their electrophoretic behavior is best described by an equation of the type:

$$u_0 = \frac{Q}{A\pi r^2 \eta}$$

where  $A$  is a shape factor generally in the range of 4 to 6, which shows an inverse dependence of the mobility on the square of the radius. In terms of molecular weight, this implies an inverse dependence of mobility on the  $2/3$  power of the molecular weight.

**Effect of pH**— The direction and rate of migration of molecules containing a variety of ionizable functional groups, such as amino acids and proteins, depends upon the pH of the electrolyte. For instance, the mobility of a simple amino acid such as glycine varies with pH approximately as shown in [Figure 1](#).

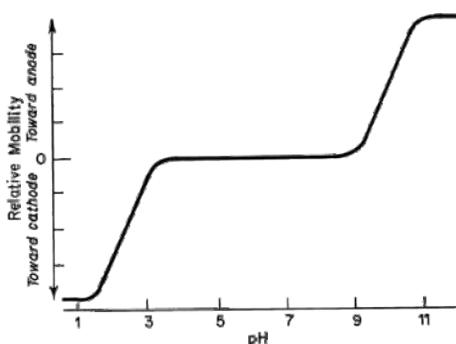

Fig. 1.

The  $pK_a$  values of 2.2 and 9.9 coincide with the inflection points of the sigmoid portions of the plot. Since the respective functional groups are 50% ionized at the pH values where  $pH = pK_a$ , the electrophoretic mobilities at these points are half of the value observed for the fully ionized cation and anion obtained at very low and very high pH, respectively. The zwitterion that exists at the intermediate pH range is electrically neutral and has zero mobility.

**Effect of Ionic Strength and Temperature**— Electrophoretic mobility decreases with increasing ionic strength of the supporting electrolyte. Ionic strength,  $\mu$ , is defined as:

$$\mu = 0.5 \sum C_i Z_i^2$$

where  $C_i$  is the concentration of an ion in moles per L and  $Z_i$  is its valence, and the sum is calculated for all ions in the solution. For buffers in which both the anion and cation are univalent, ionic strength is identical with molarity.

Ionic strengths of electrolytes employed in electrophoresis commonly range from about 0.01 to 0.10. A suitable strength is somewhat dependent on the sample composition, since the buffer capacity must be great enough to maintain a constant pH over the area of the component zones. Zones become sharper or more compact as ionic strength is increased.

Temperature affects mobility indirectly, since the viscosity,  $\eta$ , of the supporting electrolyte is temperature-dependent. The viscosity of water decreases at a rate of about 3% per  $^{\circ}\text{C}$  in the range of  $0^{\circ}$  to  $5^{\circ}$  and at a slightly lower rate in the vicinity of room temperature. Mobility, therefore, increases with increasing electrolyte temperature.

Considerable heat is evolved as a result of current passing through the supporting electrolyte. This heat increases with the applied voltage and with increasing ionic strength. Particularly in larger apparatus, despite the circulation of a coolant, this heat produces a temperature gradient across the bed which may lead to distortion of the separated zones. Therefore, practical considerations and the design of the particular apparatus dictate the choice of ionic strength and operating voltage.

effect of a Stabilizing Medium, Electroosmosis— When an electrical current is passed through an electrolyte contained in a glass tube or contained between plates of glass or plastic, bulk flow of the electrolyte toward one of the electrodes is observed. This flow is called electroosmosis. It results from the surface charge on the walls of the apparatus, which arises either from ionizable functional groups inherent in the structural material or from ions adsorbed on the cell walls from the electrolyte contacting them. The effect is usually increased when the cell is filled with a bed of porous substance, such as a gel, used to stabilize the supporting electrolyte and prevent remixing of separated zones by thermal convection or diffusion. The solution immediately adjacent to the surface builds up an electrical charge, equal but opposite to the surface charge, and the electrical field traversing the cell produces a movement of solution toward the electrode of opposite charge.

The substances commonly used as stabilizing media in zone electrophoresis develop a negative surface charge, and therefore electroosmotic flow of the electrolyte is toward the cathode. As a result, all zones, including neutral substances, are carried toward the cathode during the electrophoretic run.

The degree of electroosmosis observed varies with the stabilizing substance. It is appreciable with agar gel, while it is negligibly small with polyacrylamide gel.

Molecular Sieving— In the absence of a stabilizing medium or in cases where the medium is very porous, electrophoretic separation of molecules results from differences in the ratio of their electrical charge to their size. In the presence of a stabilizing medium, differences in adsorptive or other affinity of molecules for the medium introduces a chromatographic effect that may enhance the separation.

If the stabilizing medium is a highly cross-linked gel such that the size of the resultant pores is of the order of the dimensions of the molecules being separated, a molecular sieving effect is obtained. This effect is analogous to that obtained in separations based on gel permeation or molecular exclusion chromatography, but in gel electrophoresis the effect is superimposed on the electrophoretic separation. Molecular sieving may be visualized to result from a steric barrier to the passage of larger molecules. Small molecules pass through pores of a wide size range, and therefore their electrophoretic passage through the gel will not be impeded. As size increases, fewer pores will permit passage of the molecules, causing a retardation of the migration of substances of large molecular weight.

#### Gel Electrophoresis

Processes employing a gel such as agar, starch, or polyacrylamide as a stabilizing medium are broadly termed gel electrophoresis. The method is particularly advantageous for protein separations. The separation obtained depends upon the electrical charge to size ratio coupled with a molecular sieving effect dependent primarily on the molecular weight.

Polyacrylamide gel has several advantages that account for its extensive use. It has minimal adsorptive properties and produces a negligible electroosmotic effect. Gels of a wide range of pore size can be reproducibly prepared by varying the total gel concentration (based on monomer plus cross-linking agent) and the percentage of cross-linking agent used to form the gel. These quantities are conveniently expressed as

$$T(\%) = \frac{a + b}{V} 100$$
$$C(\%) = \frac{b}{a + b} 100$$

where T is the total gel concentration in %; C is the percentage of cross-linking agent used to prepare the gel; V is the volume, in mL, of buffer used in preparing the gel; and a and b are the weights, in g, of monomer (acrylamide) and cross-linking agent (usually N,N'-methylenebisacrylamide) used to prepare the gel. Satisfactory gels ranging in concentration (T) from about 3% to 30% have been prepared. The amount of cross-linking agent is usually about one-tenth to one-twentieth of the quantity of monomer (C = 10% to 5%), a smaller percentage being used for higher values of T.

In the preparation of the gel, the bed of the electrophoresis apparatus is filled with an aqueous solution of monomer and cross-linking agent, usually buffered to the pH desired in the later run, and polymerized in place by a free radical process. Polymerization may be initiated by a chemical process, frequently using ammonium persulfate plus N,N,N',N'-tetramethylenediamine or photochemically using a mixture of riboflavin and N,N,N',N'-tetramethylenediamine. Polymerization is inhibited by molecular oxygen and by acidic conditions. The gel composition and polymerization conditions chosen must be adhered to rigorously to ensure reproducible qualities of the gel.

Apparatus for Gel Electrophoresis— In general, the bed or medium in which electrophoresis is carried out may be supported horizontally or vertically, depending upon the design of the apparatus. A series of separations to be compared may also be carried out in several individual tubes or by placing different samples in adjacent wells, cast or cut into a single slab of gel. A vertical slab assembly such as that depicted schematically in Figure 2

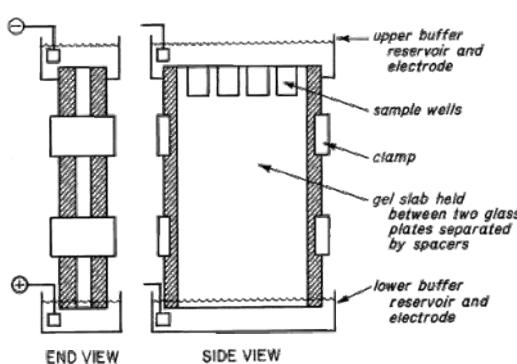

Fig. 2. Vertical Slab Gel Electrophoresis Apparatus.

is convenient for direct comparison of several samples. A particular advantage derives from the comparison of the samples in a single bed of gel which is likely to be more uniform in composition than gels cast in a series of chambers.

A feature of many types of apparatus, not illustrated in the schematic view, seals the lower buffer chamber to the base of the bed and allows the level of the buffer in the lower chamber to be made equal to that in the upper chamber, thereby eliminating hydrostatic pressure on the gel. In addition, some units provide for the circulation of coolant on one or both sides of the gel bed.

In the preparation of the gel, the base of the gel chamber is closed with a suitable device and the unit is filled with the solution of monomer, cross-linking agent, and catalyst. A comb, having teeth of an appropriate size, is inserted in the top, and polymerization is allowed to proceed to completion. Removal of the comb leaves a series of sample wells in the polymerized gel.

In simple gel electrophoresis, an identical buffer is used to fill the upper and lower buffer chambers as well as in the solution used to prepare the gel. After filling the chambers, the samples, dissolved in sucrose or other dense and somewhat viscous solution to prevent diffusion, are introduced with a syringe or micropipet into the bottoms of the sample wells, and

the electrophoresis is begun immediately thereafter.

#### disk electrophoresis

An important variant of polyacrylamide gel electrophoresis, which employs a discontinuous series of buffers and often also a discontinuous series of gel layers, is called disk electrophoresis. The name is derived from the discoid shape of the very narrow zones that result from the technique. As a result of the narrow zones produced, this technique exhibits an extremely high resolving power and is to be recommended for the characterization of protein mixtures and for the detection of contaminants that may have mobilities close to that of the major component.

The basis of disk electrophoresis is outlined in the following paragraphs with reference to an anionic system suitable for separating proteins bearing a net negative charge. To understand disk electrophoresis, it is essential to have a knowledge of the general aspects of electrophoresis and the apparatus already described.

**Basis of Disk Electrophoresis**— The high resolution obtained in disk electrophoresis depends on the use of a buffer system that is discontinuous with respect to both pH and composition. This is usually combined with a discontinuous series of two or three gels that differ in density.

A typical system is illustrated schematically in [Figure 3](#).

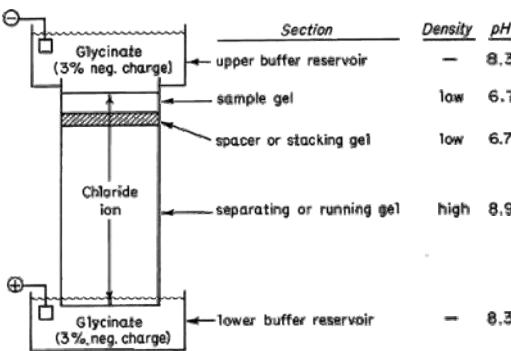

Fig. 3. Terminology, Buffer pH, and Buffer Composition for Acrylamide Gel Disk Electrophoresis.

A high density ( $T = 10\text{ to }30\%$ ) separating gel several centimeters high is polymerized in a tris-chloride buffer in the bed of the apparatus. During polymerization the buffer is overlaid with a thin layer of water to prevent fixation of a meniscus in the top of the gel. The overlayer of water is then removed and a thin layer, 3 mm to 10 mm thick, of low density ( $T = 3\%$ ) gel, called the spacer or stacking gel, is polymerized in a tris-chloride buffer on top of the separating gel. An overlayer of water is again used to ensure a flat surface.

The sample is mixed with a small amount of the spacer gel monomer solution which is applied on top of the spacer gel and allowed to polymerize. The pH of the separating gel is typically 8.9, while that of the spacer and sample gels is 6.7. All three gels are prepared using chloride as the anion.

The upper and lower buffer reservoirs are filled with a pH 8.3 buffer prepared from tris and glycine. At this pH about 3% of the glycine molecules bear a net negative charge.

When a voltage is applied across the system, the glycinate-chloride interface moves downward toward the anode. It was initially positioned at the junction of the buffer in the upper reservoir and the top of the sample gel layer. The chloride anion, by virtue of its small size, migrates faster than any of the proteins present in the sample. The pH of the sample and spacer layers was chosen to be about 3 units below the higher  $pK_a$  of glycine. Therefore, in traversing these layers, only about 0.1% of the glycine molecules bear a net negative charge. Consequently, glycine migrates more slowly than chloride. The tendency for the faster-moving chloride to move away from glycinate lowers the concentration at the interface, producing a greater voltage drop at the interface, which in turn causes the glycinate to catch up to the chloride. Under these conditions, a very sharp interface is maintained, and as it moves through the sample and spacer layers, the proteins in the sample tend to stack themselves at the interface in very thin layers in order of mobility. The process is called stacking and is the source of the disks which are separated.

When the stacked proteins reach the high-density separating gel, they are slowed down by a molecular sieving process. The higher pH encountered in the running gel also causes the glycinate to migrate faster, so that the discontinuous buffer interface overtakes the proteins and eventually reaches the bottom of the separating gel. During this period, the disks of protein continue to separate by electrophoresis and molecular sieving in the separating gel. At the end of the run, the pH of the separating gel will have risen above its original value of 8.9 to a value of about pH 9.5.

**Relative Mobility**— Bromophenol blue is often used as a standard for calculating the relative mobility of separated zones and to judge visually the progress of a run. It may be added to one of the sample wells, or mixed with the sample itself, or simply added to the buffer in the upper sample reservoir.

Relative mobility,  $M_B$ , is calculated as:

$$M_B = \frac{\text{distance from origin to sample zone}}{\text{distance from origin to bromophenol blue zone}}$$

**Visualization of Zones**— Since polyacrylamide is transparent, protein bands may be located by scanning in a densitometer with UV light. The zones may be fixed by immersing in protein precipitants such as phosphotungstic acid or 10% trichloroacetic acid. A variety of staining reagents including naphthalene black (amido black) and Coomassie brilliant blue R250 may be used. The fixed or stained zones may be conveniently viewed and photographed with transmitted light from an X-ray film illuminator.

#### safety precautions

Voltages used in electrophoresis can readily deliver a lethal shock. The hazard is increased by the use of aqueous buffer solutions and the possibility of working in damp environments.

The equipment, with the possible exception of the power supply, should be enclosed in either a grounded metal case or a case made of insulating material. The case should have an interlock that deenergizes the power supply when the case is opened, after which reactivation should be prevented until activation of a reset switch is carried out.

High-voltage cables from the power supply to the apparatus should preferably be a type in which a braided metal shield completely encloses the insulated central conductor, and the shield should be grounded. The base of the apparatus should be grounded metal or contain a grounded metal rim which is constructed in such a way that any leakage of electrolyte will produce a short which will deenergize the power supply before the electrolyte can flow beyond the protective enclosure.

If the power supply contains capacitors as part of a filter circuit, it should also contain a bleeder resistor to ensure discharge of the capacitors before the protective case is opened. A shorting bar that is activated by opening the case may be considered as an added precaution.

Because of the potential hazard associated with electrophoresis, laboratory personnel should be completely familiar with electrophoresis equipment before using it.

Auxiliary Information— Please [check for your question in the FAQs](#) before contacting USP.

## 72 CAPILLARY ELECTROPHORESIS

Electrophoresis refers to the migration of charged electrical species when dissolved or suspended in an electrolyte through which an electric current is passed. Cations migrate toward the negatively charged electrode (cathode), while anions are attracted toward the positively charged electrode (anode). Neutral particles are not attracted toward either electrode.

The use of capillaries as a migration channel in electrophoresis has enabled analysts to perform electrophoretic separations on an instrumental level comparable to that of high-performance liquid chromatography (HPLC), albeit with some distinct operational differences, advantages, and disadvantages relative to HPLC. This method of analysis is commonly known as capillary electrophoresis (CE). During typical CE operation with an uncoated capillary filled with a buffer, referred to as the "operating buffer," silanol groups present on the inner wall of the glass capillary release hydrogen ions to the buffer and the wall surface becomes negatively charged, even at a fairly low pH. Cations, or solutes having partial positive charges in the medium, are electrostatically attracted to the negatively charged wall, forming an electrical double layer. The initiation of electrophoresis by applying voltage across the length of the capillary causes the solution portion of the electrical double layer to move toward the cathode end of the capillary, drawing the bulk solution. This movement of the bulk solution under the force of the electrical field is called the electroosmotic flow (EOF). The degree of ionization of the inner-wall capillary silanol groups depends mainly on the pH of the operating buffer and on the modifiers that may have been added to the electrolyte. At low pH, the silanol groups generally have a low ionization and the EOF is low. At higher pH, silanol groups become more ionized and the EOF increases. In some cases organic solvents, such as methanol or acetonitrile, are added to the aqueous buffer to increase the solubility of the solute and other additives or to affect the degree of ionization of the sample. The addition of such organic modifiers generally causes a decrease in the EOF. The detector is located toward the cathode end of the capillary. The EOF is usually greater than the electrophoretic mobility; thus, even anions are swept toward the cathode and the detector. When an uncoated capillary containing pH 7.0 phosphate buffer is used, the usual order of appearance of solutes in an electropherogram is cationic species, neutral solutes, and anionic species.

Currently, there are five major modes of operation of CE: capillary zone electrophoresis (CZE), also referred to as free solution or free flow capillary electrophoresis; micellar electrokinetic chromatography (MEKC); capillary gel electrophoresis (CGE); capillary isoelectric focusing (CIEF); and capillary isotachophoresis (CITP).

In CZE, separations are controlled by differences in the relative electrophoretic mobilities of the individual components in the sample or test solution. The mobility differences are functions of analyte charge and size under specific method conditions. They are optimized by appropriate control of the composition of the buffer, its pH, and its ionic strength.

In MEKC, ionic surfactants are added to the operating buffer at a concentration above their critical micelle concentration. The micelles provide a pseudostationary phase with which analytes can partition. This technique is useful for the separation of neutral and ionic species.

CGE, which is analogous to gel filtration, uses gel-filled capillaries to separate molecules on the basis of relative differences in their respective molecular weight or molecular size. It was first used for the separation of proteins, peptides, and oligomers. Gels may have the advantage of decreasing the EOF and also significantly reducing protein adsorption onto the inner wall of the capillary, which can significantly reduce analyte peak tailing effects.

In CIEF, substances are separated on the basis of their relative differences in isoelectric points. This is accomplished by achieving steady-state sample zones within a buffer pH gradient, where the pH is low at the anode and high at the cathode. The gradient is established by applying a voltage across a capillary filled with a mixture of carrier components consisting of amphoteric substances having different pI values.

CITP employs two buffers that enclose the analyte zones between them. Either anions or cations can be analyzed in sharply separated zones. In addition, the analyte concentrations are the same in each zone; thus, the length of each zone is proportional to the amount of the particular analyte.

The most commonly utilized capillary electrophoresis techniques are CZE and MEKC. These are briefly discussed in the following sections. Pertinent general principles and theory, instrumental considerations, analysis, and operational considerations and parameters are discussed as well.

### PRINCIPLES OF CAPILLARY ZONE ELECTROPHORESIS

CZE makes use of the principles of electrophoresis and electroosmosis to achieve separation of charged species.

(1) The electrophoretic mobility of an ion,  $\mu_{EP}$ , is described by the equation:

$$\mu_{EP} = q / (6\pi\eta r)$$

in which  $q$  is the charge of the ion,  $\eta$  is the solution viscosity, and  $r$  is the radius of the hydrated ion. This relationship infers that small, highly charged analytes have high mobilities and large, slightly charged analytes have low mobilities.

(2) The velocity of migration,  $V_{EP}$ , in cm per second, is represented by the equation:

$$V_{EP} = \mu_{EP}(V / L)$$

in which  $\mu_{EP}$  is the electrophoretic mobility;  $V$  is the applied voltage; and  $L$ , in cm, is the total capillary length.

(3) The velocity of the EOF,  $V_{EO}$ , in cm per second, is described by the equation:

$$V_{EO} = \mu_{EO}(V / L)$$

in which  $\mu_{EO}$  is the EOF mobility (the coefficient of electroosmotic flow), and the other terms are as defined above.

(4) The time,  $t$ , in seconds, necessary for a solute to migrate the entire effective length of the capillary (from the inlet to the detector),  $l$ , is represented by the relationship:

$$t = l / E(\mu_{EP} + \mu_{EO}) = l / V(\mu_{EP} + \mu_{EO})$$

in which  $E$  is the strength of the applied electrical field, and the other terms are as defined above.

(5) Efficiency of an electrophoretic system can be related to mobility and EOF and expressed in terms of the number of theoretical plates,  $N$ , by the equation:

$$N = (\mu_{EP} + \mu_{EO})V / 2D$$

in which  $D$  is the diffusion coefficient of the solute, and the other terms are as defined above.

(6) The resolution,  $R$ , of two consecutively eluting solutes can be defined by the equation:

$$R = 0.18(\mu_{EP1} - \mu_{EP2})[V/D(\mu_{EP} + \mu_{EO})]^{1/2}$$

where  $\mu_{EP1}$  and  $\mu_{EP2}$  are the mobilities of the two solutes,

# $\mu_{EP}$

is their average, and the other terms are as defined above.

## PRINCIPLES OF MICELLAR ELECTROKINETIC CHROMATOGRAPHY

In MEKC, the supporting electrolyte medium contains a surfactant at a concentration above its critical micelle concentration (CMC). In this aqueous medium, the surfactant self-aggregates and forms micelles whose hydrophilic head groups form an outer shell and whose hydrophobic tail groups form a nonpolar core into which the solutes can partition. Generally, the micelles are anionic on their surface, and, under the applied voltage, they migrate in the opposite direction to the EOF. This type of partitioning is analogous to that in solvent extraction or reverse-phase HPLC. The differential partitioning of neutral molecules between the buffered aqueous mobile phase and the micellar pseudostationary phase is the sole basis for separation. The buffer and micelles form a two-phase system, and the analyte can partition between these two phases.

A micellar system suitable for MEKC meets the following criteria: the surfactant is highly soluble in the buffer, and the micellar solution is homogeneous and transparent when UV detection is employed. The most common surfactant for MEKC is sodium dodecyl sulfate (anionic surfactant). Others include cetyltrimethylammonium bromide (cationic surfactant) and bile salts (chiral surfactant). The selectivity of an MEKC system is mainly dependent on the nature of the surfactant. Organic solvents are often added to the MEKC buffer to adjust the capacity factors, just as in reverse-phase HPLC separations. MEKC may be used for the separation of enantiomers. For such separations, a chiral additive is added to the buffer or a chiral surfactant, such as a bile salt, is used.

A general knowledge of conventional column chromatographic principles aids in understanding MEKC principles. However, in MEKC the micelles are not truly stationary; therefore, the column chromatographic theory needs to be modified. The major modification introduced to MEKC principles is the finite nature of the separation window for neutral molecules.

(7) The migration time,  $t_R$ , for a neutral species is expressed with the following equation:

$$t_R = (1 + k')t_0 / [1 + (t_0 / t_{MC})]$$

in which  $t_0$  is the time required for an unretained substance to travel the effective length of the capillary;  $t_{MC}$  is the time required for a micelle to traverse the capillary;  $k'$  is the capacity factor; and  $t_R$  is always between  $t_0$  and  $t_{MC}$ .

(8) The capacity factor,  $k'$ , for a neutral species, is calculated by the equation:

$$k' = (t_R / t_0 - 1) / (1 - t_R / t_{MC})$$

in which the terms are as defined above.

(9) For practical purposes,  $k'$  is calculated by the equation:

$$k' = t_R / t_0 - 1$$

in which  $t_R$  is the time measured from the point of voltage application (or injection) to the peak maximum; and  $t_0$  is measured from the point of voltage application (or injection) to the leading edge of the solvent front or of an unretained substance. In contrast with CZE,  $k'$  in MEKC is significant and is a characteristic of a given solute in a given MEKC system. Further discussion of  $k'$  appears later in the System Suitability section under Operational Parameters.

(10) The resolution,  $R_S$ , for neutral species is calculated by the equation:

$$R_S = [(\sqrt{N})/4][(\alpha - 1)/\alpha][k'_2/(1 + k'_2)][(1 - (t_0/t_{MC}))/\{1 + (t_0/t_{MC})k'_1\}]$$

in which  $\alpha$  is the selectivity, defined as the ratio of  $k'_2$  to  $k'_1$ , of the operating conditions for separating two solutes. If the two solutes elute close together ( $\alpha \leq 1.1$ ), either  $k'$  may be used. The equation shows that, just as with conventional chromatography, resolution in MEKC can be improved through controlling efficiency, selectivity, retention, and the chemical nature of the resolving surfactant-medium system. The last term of the equation is due to the limited elution range. Although MEKC is particularly useful in the separation of neutral species, this technique may also be used for the separation of charged solutes. The latter procedure involves a combination of chromatographic and electrophoretic separation mechanisms. The additional interaction between charged solutes and micelle can be used to optimize a separation. Ion-pairs may form if the charges borne on the surfactant and solute are opposite; otherwise, surfactant and solute repel each other. These differences can significantly influence the separation of charged molecules.

## INSTRUMENTAL CONSIDERATIONS

A typical CE system (see [Figure 1](#)) contains a fused-silica capillary having an internal diameter of 50 to 100  $\mu\text{m}$  and a length of 20 to 100 cm. The ends of the capillary are placed in separate electrolyte reservoirs. The direct-current power supply is capable of furnishing high voltages, typically ranging from 0 to 30 kV. A detector and autosampler with some form of data-recording device complete the system. An automatic buffer replenishment system and a computer-based control and data acquisition system may also be found on the standard commercial systems. Temperature controls for both the capillary and the autosampler are also available on commercial instruments.

The primary considerations of instrumentation include capillary type and configuration, modes of sampling, power supply and detector modes.

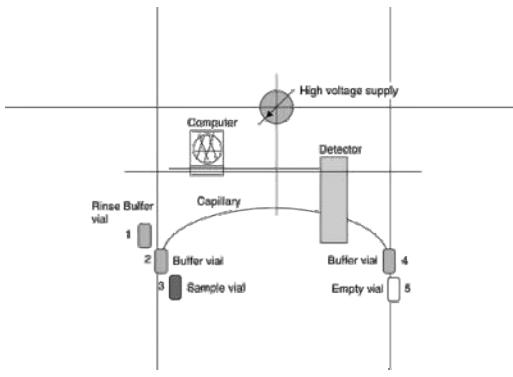

Fig. 1. Typical CE Instrument Configuration.  
Capillary Type and Configuration

Capillaries used in CZE are usually made of fused silica and with no internal coating. Some instruments are configured with a "free-swinging" style of capillary; that is, the capillary is not encased within an enclosure. In most commercial instruments, the capillary is housed in a cartridge. Both configurations offer specific advantages and disadvantages. The ability of the instrument to accommodate different types of capillaries and capillaries of various diameters and lengths is an important consideration. Capillaries with a variety of internal coatings are also available; therefore, the ability of the instrument to accommodate different capillaries is important. Internal capillary coatings may be employed to alter the magnitude or direction of EOF or to reduce sample absorption. If an internally coated capillary is to be used, then sufficient details and the indication of the supplier must be included in the method. Capillaries from an alternate supplier can be used if it is demonstrated that they are suitable.

#### Sample Introduction and Injector Technology

Modes of sample introduction onto the capillary include electromigration (electrokinetic mode) and negative- and positive-pressure injection (hydrostatic mode).

For injection via electromigration, the sample solution is electrophoresed into the capillary by inserting the capillary and electrode into the sample vials and applying a brief, high voltage. The sample enters the capillary by a combination of electrophoresis and EOF. Therefore, analytes with different mobilities are loaded into the capillary to different extents. The conductivities of the sample and standard solutes also affect the EOF and the volume injected.

Negative-pressure injectors place negative pressure at the detector end of the capillary and draw the sample solution into the injection end of the capillary. Positive-pressure injectors pressurize the sample vial, forcing the sample into the capillary. Pressure injection loads all sample components into the capillary to the same extent, and it is generally the most reproducible and the most frequently applied injection mode. The sample volume injected depends on the capillary length and internal diameter and the voltage or pressure applied. The typical sample volumes injected into the capillary are between 1 and 20 nL.

Each injection method offers specific advantages and disadvantages, depending on the sample composition, the separation mode, and the application of the method. None of the above injection modes is as reproducible as commercially available HPLC injectors. Based on the circumstances, it may be necessary to use internal standards for specific methods where high injection precision is required.

#### Power Supply

Most commercially available CE units have direct-current power supplies that are capable of furnishing power on a ramp-up or step-function mode to achieve and maintain the desired operational voltage in a smooth manner. This will help to ensure a relatively smooth baseline.

Another essential feature of the power supply is its utility in introducing a sample at the cathodic or the anodic end of the capillary. Because it is impractical to relocate the on-line detector from one end of the instrument to the other, it is beneficial to be able to specify whether the sample injection end is at the cathode or the anode.

#### Detector Modes

CE systems generally offer UV-visible absorbance and laser-induced fluorescence (LIF) detectors. Scanning UV detectors or photodiode-array detectors are also available for many commercial CE instruments.

The coupling of CE to a mass spectrometer offers the possibility of obtaining structural information in conjunction with electrophoretic migration data.

Fluorescence detection offers an enhanced sensitivity for samples containing only very small amounts of UV-active analytes. Application of fluorescent tags to non-UV-absorbing compounds can be useful. Alternately, non-UV-absorbing or nonfluorescent analytes can be detected indirectly by adding a chromophore or a fluorophore, respectively, to the buffer: the non-absorbing species are detected through the absence of expected signal from the absorbing species. Conductivity and pulsed amperometric detectors can also be used but are not generally available on commercial CE instruments.

#### ANALYTICAL CONSIDERATIONS

Several parameters, namely, capillary dimensions, voltage, ionic strength, and pH, are optimized to give adequate resolution and separation. Care should be taken to avoid changes in temperature that will affect the viscosity of the buffer and, in turn, influence both the EOF and the solute mobilities.

**Capillary Dimensions**— Variation of the capillary diameter and length can affect the electrophoretic resolution. Increasing the capillary length results in longer migration times, usually increasing resolution and generating a lower current. Increasing the capillary diameter will usually increase current and associated internal temperature gradients that decrease resolution. Conversely, a reduction in capillary diameter will result in lower heat and better resolution. However, larger capillary diameters have advantages of better mass loading and improved signal-to-noise ratio.

**Voltage Effects**— When higher voltages are applied, additional internal heating of the operating buffer occurs because of the current flow through the buffer. This heating effect, known as Joule heating, must be controlled because resistance, dielectric constant, and viscosity are temperature-dependent and alter the velocity of the EOF and solute mobilities.

In general, increasing the voltage will result in increased efficiency and resolution (up to the point where Joule heat cannot be adequately dissipated). Maximum resolution is obtained by maintaining the voltage below the level at which Joule heating and diffusion become limiting factors.

**Ionic Strength Effects**— Control of ionic strength and its manipulation allow adjustment of resolution, efficiency, and sensitivity. Increasing ionic strength will generally improve resolution, peak efficiency, and peak shape. Sensitivity may be improved because better focusing is achieved. However, because the current generated is directly proportional to the buffer concentration, more heat is produced when ionic strength of the buffer is increased, hence limiting the ionic strengths that can be utilized.

**pH Effects**— Resolution, selectivity, and peak shape can be dramatically altered by changes in pH as this parameter affects the extent of solute ionization and the level of EOF. The EOF is high at high pH and low at low pH in uncoated fused-silica capillaries.

#### OPERATIONAL PARAMETERS

The major steps in operating a CE system are system setup, capillary rinsing procedure, running a sample, system suitability testing, sample analysis, data handling, and system shutdown.

System Setup— An appropriate capillary of specific length, inner diameter, and coating is selected, with considerations made for separation and resolution, ionic strength of buffer, and pH effects. A buffer of appropriate composition, ionic strength, and pH is prepared, degassed, if necessary, and passed through an appropriate filter. All solvents, including water, are HPLC or CE grade.

Capillary Rinsing Procedure— Improved consistency of migration times and resolution may generally be obtained if a defined rinsing procedure is followed. Capillary conditioning and rinsing procedures are very specific to the analyte, matrix, and method. Therefore, these procedures are developed as part of the method and are specified in the individual monograph. Rinsing may involve the use of solutions such as 0.1 M phosphoric acid, water, and 0.1 M sodium hydroxide. Before beginning analysis of the test specimen, the capillary may be rinsed with five column volumes of the operating buffer that is to be used for the test. When changing buffer composition, it is advisable to rinse the capillary with five column volumes of each new buffer to allow the capillary to be cleansed of the previous buffer. Use of a new uncoated fused-silica capillary usually requires a regeneration procedure to activate the surface silanol groups. This procedure may include an extended rinse with a sodium hydroxide solution. Coated capillaries are rinsed according to the manufacturer's guidelines because inappropriate rinsing can remove or damage the coating. Columns may be dedicated to particular methods or buffer types to prevent cross-contamination.

Running a Sample— An appropriate capillary, electrolyte, and injection procedure are selected to achieve adequate resolution, sensitivity, and separation, with well-shaped and well-defined peaks. The required injection precision for a specific method may require use of an internal standard. The internal standard is selected with consideration of its ability to adequately separate from the analyte. The performance of the system may be improved by rinsing the capillary between injections and supplying fresh buffer to the source and destination vials used during voltage application, namely, vials 2 and 4 in [Figure 1](#). Replicate injections from the same sample vial may be performed provided that no cross-contamination occurs. If cross-contamination occurs, the capillary tip may be rinsed by briefly inserting it into a vial containing the buffer prior to inserting the capillary into the electrolyte or sample vial.

The operational parameters are specified in each individual monograph so as to minimize voltage effects, ionic strength effects, and pH effects. The instrument is set up to run with the appropriate capillary configuration and injection conditions, within the established linear dynamic range of the detector; and acceptable migration precision is ensured by appropriate choice of sample diluent, separation electrolyte, electrolyte additives, and capillary pretreatment conditions. Exercise caution to avoid overloading the capillary with sample, as this decreases efficiency and reproducibility.

System Suitability— Parameters measured may include injector reproducibility, system selectivity, system efficiency, and tailing. Resolution between the analytes and other compounds may be determined by using test mixture standards.

Parameters typically used to determine system suitability include relative standard deviation (RSD), capacity factor ( $k'$ ), the number of theoretical plates (N), sensitivity (limit of detection or quantitation), number of theoretical plates per meter (TPM), tailing factor (T), and resolution (R).

The peak shape is closely examined; ideally, the peak is symmetrical, with no shoulders and no excessive tailing. If these conditions are not met, corrective actions are taken before proceeding with the analysis. Peak integration is also closely examined to ensure that the peak response is correctly quantitated.

Replicate injections of a Standard preparation of known concentration can be used to determine the reproducibility of the CE system. Data from five or more replicate injections are used to calculate RSD. Unless otherwise specified in the individual monograph, the relative standard deviation for replicate injections is not more than 3.0%. Minimum injection precision values may be specified in specific CE methods, especially when determining trace-level components. Calculation of electrophoretic parameters in MEKC, as in other forms of CE, may involve a combination of chromatographic and electrophoretic relationships. Hence, capacity factor,  $k'$ , for neutral analyte migration in MEKC can be calculated by the equation:

$$k' = tR - t0(1 - tR / tMC)$$

in which  $tR$ ,  $t0$ , and  $tMC$  are the migration times of the analyte, the bulk solution (EOF), and the micelle, respectively.

The number of theoretical plates, N, is a measure of the efficiency of the system and is calculated by the equation:

$$N = 16(tR / W)^2 \text{ or } N = 5.54(tR / W1/2)^2$$

in which W is the analyte peak width at baseline,  $W1/2$  is the analyte peak width at half-height, and  $tR$  is the analyte migration time.

The number of theoretical plates per meter, TPM, is a measure of the efficiency of the capillary as a function of peak width at baseline and can be calculated by the equation:

$$TPM = 1600(tR / W)^2 / L$$

in which L, in cm, is the total capillary length; and the other terms are as defined above. The tailing factor, T, of the analyte peak is a measure of peak symmetry, and it represents the degree of deviation of the symmetry of the peak from an ideally symmetrical Gaussian peak. This factor can be calculated by the equation:

$$T = W0.05 / 2f$$

in which  $W0.05$  is the length of a line constructed parallel to the peak base from the leading edge to the tailing edge of the peak at 5% of peak height; and  $f$  is the distance along the same line from the leading edge of the peak, appearing to the left of the peak maximum in the electropherogram, to the intercept of a perpendicular line dropped from the peak maximum to the base. A ratio of 1.0 indicates a perfectly symmetrical peak. If electrodispersive effects occur, they can generate highly asymmetrical peaks. This can occur when high sample concentrations are used, such as those for testing of impurities. Use of highly asymmetrical peaks is acceptable provided that they are reproducible and that they do not compromise separation selectivity.

The resolution factor, R, is a measure of the ability of the capillary system to separate consecutively migrating analytes. Resolution is determined for all sample analytes of interest, with the pH of the buffer adjusted as necessary to meet system suitability requirements. It can be calculated by the equation:

$$R = 2(t2 - t1) / (W1 + W2)$$

in which  $t2$  and  $t1$  are the migration times, measured at peak maxima, for the slower migrating peak and the faster migrating peak, respectively; and  $W2$  and  $W1$  are the corresponding widths of these two peaks measured at their bases.

Sample Analysis— Once the suitability of the CE system has been established, aliquots of both the Standard preparation and the test preparation are injected. Standards are injected before or after the samples and intermittently throughout the run.

Data Handling— Time-normalized peak areas are often used in quantitative calculations. These are determined by dividing the observed integrated peak area by the migration time of the analyte. This compensates for the fact that in CE, unlike HPLC, each analyte travels through the detector at a different velocity. Unless this normalization is performed, slowly moving (later-migrating) analytes will have disproportionately large peak areas compared with those for early migrating components.

System Shutdown— After analysis, the capillary is rinsed according to the directions specified in each monograph or as recommended by the manufacturer. For example, the capillary might be rinsed with distilled water to remove buffer components and then filled with air or nitrogen by performing a rinse from an empty vial. Naturally, the destination and source vials, namely, vials 4 and 2 in [Figure 1](#), are emptied of buffer and rinsed thoroughly with deionized water.

## INTRODUCTION

Lipid injectable emulsions used in total parenteral nutrition (TPN) therapy are sterile oil-in-water emulsions of soybean oil, used to provide an ample supply of essential fatty acids, linoleic and linolenic, dispersed with the aid of an emulsifying agent in [Water for Injection](#). Alternatively, soybean oil can be mixed with other suitable oils (neutral triglycerides), such as safflower oil, medium-chain triglycerides (MCT) derived from coconut or palm kernel oils, olive oil, or a marine oil, such as menhaden oil. The size of the lipid droplets is critical: because of mechanical filtration, larger-size fat globules ( $>5 \mu\text{m}$ ) can be trapped in the lungs. The essential size characteristics of a lipid injectable emulsion for intravenous use includes the mean diameter of the lipid droplets and the range of the various droplet diameters distributed around the mean diameter, expressed as the standard deviation. In particular, the amounts of fat globules comprising the large-diameter tail of the globule size distribution are especially important with respect to infusion safety. These two regions of the globule size distribution (mean droplet size and large-diameter tail) must be controlled within specified limits.

The two methods described below are used for determination of the mean lipid droplet diameter and the distribution of large-diameter globule sizes in lipid injectable emulsions. Method I and Method II must be validated. The methods described below to assess the quality of lipid injectable emulsions are to be performed in two stages.

### METHOD I—LIGHT-SCATTERING METHOD

For the determination of the mean droplet size of lipid injectable emulsions, either of two common light-scattering techniques may be employed: (1) dynamic light scattering (DLS), also known as photon correlation spectroscopy (PCS), or (2) classical light scattering, based on Mie scattering theory. The DLS, or PCS, technique is based on analyzing the rapid temporal fluctuations in the scattered light intensity that occur due to the random Brownian motion, or diffusion, of any particles, including lipid droplets, suspended in liquid. The intensity is measured at a given angle (usually  $90^\circ$ ) by a suitable detector (e.g., photomultiplier tube) able to measure the rapidly fluctuating scattered light intensity produced by the suspended, diffusing droplets. These scattered intensity data are typically used to calculate the intensity autocorrelation function, which is a simple decaying exponential function in time for droplets of uniform size. A distribution of droplet sizes expresses itself by exponential functions of different decay times. The autocorrelation function generated by the scattered intensity data obtained from a given emulsion can be “inverted” by means of an appropriate deconvolution algorithm in order to obtain the approximate distribution of intensity-weighted diffusion coefficients. From the latter, the distribution of small-diameter droplets is calculated, using the Stokes-Einstein equation and the rules of classical (Mie) light scattering.

By contrast, classical light scattering based on Mie theory analyzes the spatial, rather than temporal, variation of the scattered light intensity by measuring the latter as a function of the scattering angle, typically over a large range of detected angles. The temporal fluctuations in the scattering intensity due to Brownian motion are averaged out in time for each angular measurement. This angular variation occurs as a consequence of the mutual interference of individual scattered waves arriving at the detector with different phases from different points within a given lipid droplet, as well as from different particles. The extent of the angular variation is significant whenever the droplet diameter is not small compared with the wavelength of the laser light (typically 635 nm). Droplets of a given size and refractive index yield a unique curve of scattering intensity vs. angle. A distribution of droplet sizes gives rise to a final angular dependence that represents the superposition, or summation, of individual (different) intensity vs. angle curves. The measured angular dependence of the scattering intensity obtained from a given emulsion sample can be inverted by means of an appropriate deconvolution algorithm and Mie scattering theory in order to obtain the approximate droplet size distribution.

Thus, light scattering, using either dynamic light scattering (i.e., temporal fluctuations due to droplet diffusion) or classical light scattering/Mie theory (i.e., average intensity vs. angle), can provide acceptable results for both the mean diameter and standard deviation of the droplet size distribution. For purposes of illustrating the method used in Method I, a dynamic light-scattering technique is described. For guidance regarding instruments employing classical Mie-theory light scattering, see [Light Diffraction Measurement of Particle Size](#) (429).

**Apparatus**—A suitable DLS/PCS instrument with or without the capability of automatic sample dilution is controlled by validated software and is used to perform the measurement, with the scattering angle typically set at  $90^\circ$ . The intensity-weighted results (mean diameter and standard deviation) are reported, provided it is clearly stated which values are given and that the necessary parameter values required for all requisite calculations are also given.

**Water**—Pass distilled water through a filter having a  $0.2\text{-}\mu\text{m}$  porosity, and degas by sonication, or use [Sterile Water for Injection](#) stored in a glass container.

**Standard Preparation**—To a pre-established volume of Water add an appropriate amount of concentrated suspension, containing NIST-traceable polystyrene latex standard particles or other suitable nanospheres. Gently mix the fluids to achieve a homogeneous suspension. The diluted suspension will be slightly turbid in appearance. If the DLS/PCS instrument is equipped with an automatic dilution system, the starting concentrated sample can be analyzed by injection directly into the instrument via a syringe, with further dilution occurring automatically to optimize the droplet concentration for analysis. Alternatively, the sample would require greater manual dilution with Water (typically by at least a factor of 10 over the first dilution), and then this sample would be instilled into a “drop-in” cuvette. The optimum dilution scheme that achieves the proper scattering intensity for the cuvette-based analysis will be determined by the instrument specifications. Thus, the concentration of latex in the final sample must be optimized for the DLS/PCS instrument used. This should be performed separately for three different size standards of approximately 100, 250, and 400 nm (triplicate analyses per size), and the corresponding results of intensity-weighted mean diameter and standard deviation should coincide with the expected values within acceptable errors.

**Test Preparation**—To a pre-established volume of Water add an appropriate volume of sample from the lipid injectable emulsion. Gently mix the fluids to achieve a homogeneous suspension. The diluted suspension will be slightly turbid in appearance. Gently mix the fluids. If the DLS/PCS instrument is equipped with an automatic dilution system, the starting concentrated sample can be analyzed by injection directly into the instrument via a syringe. Further dilution of the sample then occurs automatically to optimize the droplet concentration for analysis, ensuring that it is not so high as to cause artifacts due to multiple scattering or interdroplet interactions. Alternatively, the sample would require greater manual dilution with Water (typically by at least a factor of 10 over the first dilution), and then this sample would be instilled into a “drop-in” cuvette. The optimum dilution scheme that achieves the proper scattering intensity for the cuvette-based analysis will be determined by the instrument specifications. Thus, the concentration of lipid injectable emulsion in the final sample must be optimized for the DLS/PCS instrument used.

**System Suitability**—Using the Standard Preparation, measure the intensity-weighted mean particle diameter and the corresponding standard deviation. The system is suitable once the sample temperature has reached equilibration and the results have stabilized and triplicate mean droplet diameter measurements are obtained. The coefficient of variation (CV) should not exceed 10% of the NIST-traceable mean droplet diameter. A larger CV value indicates that the latex microspheres are not suitable as a standard because they either inherently lack uniformity or have become aggregated to an unacceptable extent. In this case, another standard latex suspension must be selected and tested.

**Procedure and Interpretation**—If the DLS/PCS instrument is equipped with an automatic dilution system, use a disposable syringe to load the Standard Preparation or Test Preparation. If no automatic dilution system is used, transfer the appropriately diluted preparation to a cuvette and place the cuvette in the spectrometer. Allow the sample to equilibrate to a preset controlled temperature close to ambient (between  $20^\circ$  and  $25^\circ$ , as in the USP definition found in the General Notices under Preservation, Packaging, Storage, and Labeling). Set the instrument scattering angle to  $90^\circ$ , and carry out the measurements. As long as the chi-square ( $\chi^2$ ) goodness-of-fit parameter remains acceptably low (per instrument specifications), the results for the Test Preparation are acceptable. Excessive values of the  $\chi^2$  parameter suggest that the droplet distribution is not normal and may indicate an unstable emulsion. The intensity-weighted mean droplet diameter (MDD) for lipid injectable emulsions must be less than 500 nm or  $0.5\text{ }\mu\text{m}$ , irrespective of the concentration of the dispersed lipid phase.

### METHOD II—MEASUREMENT OF LARGE GLOBULE CONTENT BY LIGHT OBSCURATION OR EXTINCTION METHOD

For determination of the extent of the large-diameter droplet tail ( $>5\text{ }\mu\text{m}$ ) of lipid injectable emulsions, a light obscuration (LO) or light extinction (LE) method that employs a single-particle (globule) optical sizing (SPOS) technique is used. During application of the LE/SPOS technique, passage of a droplet through a thin optical sensing zone results in blockage of a portion of the incident light beam, causing a momentary decrease in the light intensity reaching the “extinction” detector. The magnitude of this decrease in the signal is ideally proportional to the cross-sectional area of the droplet (assumed smaller than the sensing zone thickness), i.e., to the square of the droplet diameter. During optimization of the LE/SPOS instrument for a given emulsion sample, a series of dilutions should be tested to achieve an acceptably low coefficient of variation (i.e.,  $<10\%$ ) between samples. The goal is to identify a standard range of dilutions that yield consistent data and are most applicable to the formulation tested. Ideally, when comparing different emulsions, the same approximate number of globules are sized each time, and once a standard is achieved, it should be incorporated into the routine sampling plan for validation testing. As long as the fat globule concentration is below the “coincidence limit” of the sensor (determined by the flow cell and optical design), only one globule at most will pass through the sensing zone at any given time, allowing it to be counted and accurately sized (with less than 1% coincidence events). Both the coincidence limit and the optimal flow rate must be known for the LE/SPOS sensor

used. Furthermore, it is prudent to perform the large-diameter measurements at a reduced emulsion concentration such that the measurable droplet concentration (i.e., >1.8  $\mu$ m) is only approximately one-third of the nominal coincidence limit for the sensor used. The resulting single pulse heights are converted to droplet diameters using a standard calibration curve previously constructed from NIST-traceable monosized polystyrene microspheres of known diameters. For additional guidance in the use of the light obscuration methodology, see the general chapter [Particulate Matter in Injections](#) (788).

**Apparatus**— A suitable light obscuration instrument with or without the capability of automatic sample dilution and controlled by a personal computer (PC) is used for the measurement. The number- and volume-weighted particle size distribution data are reported, provided it is clearly stated which values are given and that the necessary parameter values required for all necessary calculations are also given.

Water— Pass distilled water through a filter having a 0.2- $\mu$ m porosity, and degas by sonication, or use [Sterile Water for Injection](#) stored in a glass container.

**Standard Preparation**— To a pre-established volume of Water add an appropriate amount of concentrated suspension, containing NIST-traceable polystyrene latex standard particles or other suitable microspheres. Gently mix the fluids to achieve a homogeneous suspension. If the light obscuration instrument is equipped with an automatic dilution system, the starting concentrated sample can be analyzed by injection directly into the instrument via a syringe or Teflon sample line. Further dilution of the sample then occurs automatically to optimize the particle concentration for analysis. Alternatively, the sample would require greater manual dilution with water (typically by at least a factor of 10 over the first dilution). The resulting diluted sample is then instilled in an appropriate, clean container, such as a sterile Type I glass container, before being passed through the sensor. In either case the final particle concentration is caused to lie below the coincidence limit of the sensor. The sizing and counting accuracy of the light obscuration instrument should be obtained using three different size standards of approximately 5  $\mu$ m, 10  $\mu$ m, and 25  $\mu$ m (triplicate analyses per size). The corresponding results for the mean diameter should coincide with the expected values, within a 10% acceptable error. In addition, the number of particle counts obtained per unit volume of diluted sample suspension should also agree, within a 10% acceptable error, with the concentration values certified in the documentation provided with each NIST-traceable size standard.

**Test Preparation**— To a pre-established volume of Water add an appropriate volume of sample from the lipid injectable emulsion. Gently mix the fluids to achieve a homogeneous suspension. The diluted emulsion will be slightly turbid in appearance. If the light obscuration instrument is equipped with an automatic dilution system, the starting concentrated sample can be analyzed by injection directly into the instrument via a syringe or nonreactive Teflon sample line. Further dilution then occurs automatically to optimize the droplet/globule concentration for analysis. Alternatively, the sample would require greater manual dilution with water (typically by at least a factor of 10 over the first dilution). The resulting diluted sample is then instilled in an appropriate, clean container such as a sterile Type I glass container. In either case the final droplet/globule concentration is caused to lie below the coincidence limit of the sensor.

**System Suitability**— Using the Standard Preparation, measure the number-weighted particle diameter and the corresponding standard deviation. The system is suitable once the sample has equilibrated and the results have stabilized and triplicate mean number-weighted particle diameter measurements are obtained within 10% of each other. The measured coefficient of variation (CV) for the number-weighted particle size distribution should not deviate by more than 25% from the CV value stipulated for the NIST-traceable standard. The latter value is usually very small, assuming nearly uniform-size standard particles. Therefore, in practice the measured CV value is usually considerably larger than this ideal value, being dictated instead by the resolution of the LE/SPOS sensor. The resolution of the sensor should be sufficiently good that the measured CV value does not exceed 15% of the mean diameter of the NIST-traceable standard. A larger CV value indicates that the latex microspheres are not suitable as a standard because they either inherently lack uniformity or have become aggregated to an unacceptable extent. In this case, another standard latex suspension must be selected and tested.

**Procedure and Interpretation**— If the light obscuration instrument is equipped with an automatic dilution system, use a disposable syringe or Teflon sample line to load the Standard Preparation or Test Preparation. If no automatic dilution system is used, transfer the sample to an appropriate large-volume, clean container such as a sterile Type I glass vessel containing an appropriate volume of Water. Allow the sample and Water to mix thoroughly to achieve a homogeneous suspension. Set the instrument threshold of detection at 1.8  $\mu$ m, extended to an upper limit of 50  $\mu$ m, and employ measurement times of 120, 180, and 240 seconds for each run of each replicate of the sample (n = 3 runs per sample). As long as the three measurements of the volume-weighted percentage of fat greater than 5  $\mu$ m (PFAT5) for each sample fall within 10% of each other (irrespective of run time), the results for the Test Preparation are acceptable. Values exceeding this reproducibility tolerance suggest either that the sample is unstable or that the dilution has not been optimized. The volume-weighted, large-diameter fat globule limits of the dispersed phase, expressed as the percentage of fat residing in globules larger than 5  $\mu$ m (PFAT5) for a given lipid injectable emulsion, must be less than 0.05%.

\* Polyvinyl chloride (PVC) with diethylhexylphthalate (DEHP) has been shown to induce breakdown of lipid injectable emulsions (Drug Product Problem Reporting System. USP File Access No. 11173, May 15, 1991).

### 730 PLASMA SPECTROCHEMISTRY

Plasma-based instrumental techniques that are useful for pharmaceutical analyses fall into two major categories: those based on the inductively coupled plasma, and those where a plasma is generated at or near the surface of the sample. An inductively coupled plasma (ICP) is a high-temperature excitation source that desolvates, vaporizes, and atomizes aerosol samples and ionizes the resulting atoms. The excited analyte ions and atoms can then subsequently be detected by observing their emission lines, a method termed inductively coupled plasma-atomic emission spectroscopy (ICP-AES), also known as inductively coupled plasma-optical emission spectroscopy (ICP-OES); or the excited or ground state ions can be determined by a technique known as inductively coupled plasma-mass spectrometry (ICP-MS). ICP-AES and ICP-MS may be used for either single- or multi-element analysis, and they provide good general-purpose procedures for either sequential or simultaneous analyses over an extended linear range with good sensitivity.

An emerging technique in plasma spectrochemistry is laser-induced breakdown spectroscopy (LIBS). In LIBS, a solid, liquid, or gaseous sample is heated directly by a pulsed laser, or indirectly by a plasma generated by the laser. As a result, the sample is volatilized at the laser beam contact point, and the volatilized constituents are reduced to atoms, molecular fragments, and larger clusters in the plasma that forms at or just above the surface of the sample. Emission from the atoms and ions in the sample is collected, typically using fiber optics or a remote viewing system, and measured using an array detector such as a charge-coupled device (CCD). LIBS can be used for qualitative analysis or against a working standard curve for quantitative analysis. Although LIBS is not currently in wide use by the pharmaceutical industry, it might be suited for at-line or on-line measurements in a production setting as well as in the laboratory. Because of its potential, it should be considered a viable technique for plasma spectrochemistry in the pharmaceutical laboratory. However,

because LIBS is still an emerging technique, details will not be further discussed in this general chapter.<sup>1</sup>

### SAMPLE PREPARATION

Sample preparation is critical to the success of plasma-based analysis and is the first step in performing any analysis via ICP-AES or ICP-MS. Plasma-based techniques are heavily dependent on sample transport into the plasma, and because ICP-AES and ICP-MS share the same sample introduction system, the means by which samples are prepared may be applicable to either technique. The most conventional means by which samples are introduced into the plasma is via solution nebulization. If solution nebulization is employed, solid samples must be dissolved in order to be presented into the plasma for analysis. Samples may be dissolved in any appropriate solvent. There is a strong preference for the use of aqueous or dilute nitric acid solutions, because there are minimal interferences with these solvents compared to other solvent choices. Hydrogen peroxide, hydrochloric acid, sulfuric acid, perchloric acid, combinations of acids, or various concentrations of acids can all be used to dissolve the sample for analysis. Dilute hydrofluoric acid may also be used, but great care must be taken to ensure the safety of the analyst, as well as to protect the quartz sample introduction equipment when using this acid; specifically, the nebulizer, spray chamber, and inner torch tube should be manufactured from hydrofluoric acid-tolerant materials. Additionally, alternative means of dissolving the sample can be employed. These include, but are not limited to, the use of dilute bases, straight or diluted organic solvents, combinations of acids or bases, and combinations of organic solvents.

When samples are introduced into the plasma via solution nebulization, it is important to consider the potential matrix effects and interferences that might arise from the solvent. The use of an appropriate internal standard and/or matching the standard matrix with samples should be applied for ICP-AES and ICP-MS analyses in cases where accuracy and precision are not adequate. In either event, the selection of an appropriate internal standard should consider the analyte in question, ionization energy, wavelengths or masses, and the nature of the sample matrix.

Where a sample is found not to be soluble in any acceptable solvent, a variety of digestion techniques can be employed. These include hot-plate digestion and microwave-assisted digestions, including open-vessel and closed-vessel approaches. The decision regarding the type of digestion technique to use depends on the nature of the sample being digested, as well as on the analytes of interest.

Open-vessel digestion is generally not recommended for the analysis of volatile metals, e.g., selenium and mercury. The suitability of a digestion technique, whether open-vessel or closed-vessel, should be supported by spike recovery experiments in order to verify that, within an acceptable tolerance, volatile metals have not been lost during sample preparation.

Use acids, bases, and hydrogen peroxide of ultra-high purity, especially when ICP-MS is employed. Deionized water must be at least 18 megaohm. Check diluents for interferences before they are used in an analysis. Because it is not always possible to obtain organic solvents that are free of metals, use organic solvents of the highest quality possible with regard to metal contaminants.

It is important to consider the selection of the type, material of construction, pretreatment, and cleaning of analytical labware used in ICP-AES and ICP-MS analyses. The material must be inert and, depending on the specific application, resistant to caustics, acids, and/or organic solvents. For some analyses, diligence must be exercised to prevent the adsorption of analytes onto the surface of a vessel, particularly in ultra-trace analyses. Contamination of the sample solutions from metal and ions present in the container can also lead to inaccurate results.

The use of labware that is not certified to meet Class A tolerances for volumetric flasks is acceptable if the linearity, accuracy, and precision of the method have been experimentally demonstrated to be suitable for the purpose at hand.

#### SAMPLE INTRODUCTION

There are two ways to introduce the sample into the nebulizer: by a peristaltic pump and by self-aspiration. The peristaltic pump is preferred and serves to ensure that the flow rate of sample and standard solution to the nebulizer is the same irrespective of sample viscosity. In some cases, where a peristaltic pump is not required, self-aspiration can be used.

A wide variety of nebulizer types is available, including pneumatic (concentric and cross-flow), grid, and ultrasonic nebulizers. Micronebulizers, high-efficiency nebulizers, direct-injection high-efficiency nebulizers, and flow-injection nebulizers are also available. The selection of the nebulizer for a given analysis should consider the sample matrix, analyte, and desired sensitivity. Some nebulizers are better suited for use with viscous solutions or those containing a high concentration of dissolved solids, whereas others are better suited for use with organic solutions.

Note that the self-aspiration of a fluid is due to the Bernoulli, or Venturi, effect. Not all types of nebulizers will support self-aspiration. The use of a concentric nebulizer, for example, is required for self-aspiration of a solution.

Once a sample leaves the nebulizer as an aerosol, it enters the spray chamber, which is designed to permit only the smallest droplets of sample solution into the plasma; as a result, typically only 1% to 2% of the sample aerosol reaches the ICP, although some special-purpose nebulizers have been designed that permit virtually all of the sample aerosol to enter the ICP. As with nebulizers, there is more than one type of spray chamber available for use with ICP-AES or ICP-MS. Examples include the Scott double-pass spray chamber, as well as cyclonic spray chambers of various configurations. The spray chamber must be compatible with the sample and solvent and must equilibrate and wash out in as short a time as possible. When a spray chamber is selected, the nature of the sample matrix, the nebulizer, the desired sensitivity, and the analyte should all be considered.

Gas and liquid chromatography systems can be interfaced with ICP-AES and ICP-MS for molecular speciation, ionic speciation, or other modes of separation chemistry, based on elemental emission or mass spectrometry.

Ultimately, the selection of sample introduction hardware should be demonstrated experimentally to provide sufficient specificity, sensitivity, linearity, accuracy, and precision of the analysis at hand.

In addition to solution nebulization, it is possible to analyze solid samples directly via laser ablation (LA). In such instances, the sample enters the torch as a solid aerosol. LA-ICP-AES and LA-ICP-MS are better suited for qualitative analyses of pharmaceutical compounds because of the difficulty in obtaining appropriate standards. Nonetheless, quantitative analyses can be performed if it can be demonstrated through appropriate method validation that the available standards are adequate.<sup>2</sup>

#### STANDARD PREPARATION

Single- or multi-element standard solutions, whose concentrations are traceable to primary reference standards, such as those of the National Institute of Standards and Technology (NIST), can be purchased for use in the preparation of working standard solutions. Alternatively, standard solutions of elements can be accurately prepared from standard materials and their concentrations, determined independently, as appropriate. Working standard solutions, especially those used for ultra-trace analyses, may have limited shelf life. As a general rule, working standard solutions should be retained for no more than 24 hours unless stability is demonstrated experimentally. The selection of the standard matrix is of fundamental importance in the preparation of element standard solutions. Spike recovery experiments should be conducted with specific sample matrices in order to determine the accuracy of the method. If sample matrix effects cause excessive inaccuracies, standards, blanks, and sample solutions should be matrix matched, if possible, in order to minimize matrix interferences.

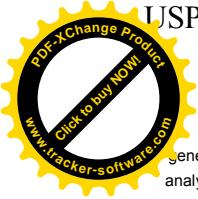

In cases where matrix matching is not possible, an appropriate internal standard or the method of standard additions should be used for ICP-AES or ICP-MS. Internal standards can also be introduced through a T connector into the sample uptake tubing. In any event, the selection of an appropriate internal standard should consider the analytes in question, their ionization and excitation energies, their chemical behavior, their wavelengths or masses, and the nature of the sample matrix. Ultimately, the selection of an internal standard should be demonstrated experimentally to provide sufficient specificity, sensitivity, linearity, accuracy, and precision of the analysis at hand.

The method of standard additions involves adding a known concentration of the analyte element to the sample at no fewer than two concentration levels plus an unspiked sample preparation. The instrument response is plotted against the concentration of the added analyte element, and a linear regression line is drawn through the data points. The absolute value of the x-intercept multiplied by any dilution factor is the concentration of the analyte in the sample.

The presence of dissolved carbon at concentrations of a small percentage in aqueous solutions enhances ionization of selenium and arsenic in an inductively coupled argon plasma. This phenomenon frequently results in a positive bias for ICP-AES and ICP-MS selenium and arsenic quantification measurements, which can be remedied by using the method of standard additions or by adding a small percentage of carbon, such as analytically pure glacial acetic acid, to the linearity standards.

#### ICP

The components that make up the ICP excitation source include the argon gas supply, torch, radio frequency (RF) induction coil, impedance-matching unit, and RF generator. Argon gas is almost universally used in an ICP. The plasma torch consists of three concentric tubes designated as the inner, the intermediate, and the outer tube. The intermediate and outer tubes are almost universally made of quartz. The inner tube can be made of quartz or alumina if the analysis is conducted with solutions containing hydrofluoric acid. The nebulizer gas flow carries the aerosol of the sample solution into and through the inner tube of the torch and into the plasma. The intermediate tube carries the intermediate (sometimes referred to as the auxiliary) gas. The intermediate gas flow helps to lift the plasma off the inner and intermediate tubes to prevent their melting and the deposition of carbon and salts on the inner tube. The outer tube carries the outer (sometimes referred to as the plasma or coolant) gas, which is used to form and sustain the toroidal plasma. The tangential flow of the coolant gas through the torch constricts the plasma and prevents the ICP from expanding to fill the outer tube, keeping the torch from melting. An RF induction coil, also called the load coil, surrounds the torch and produces an oscillating magnetic field, which in turn sets up an oscillating current in the ions and electrons produced from the argon. The impedance-matching unit serves to efficiently couple the RF energy from the generator to the load coil. The unit can be of either the active or the passive type. An active matching unit adjusts the impedance of the RF power by means of a capacitive network, whereas the passive type adjusts the impedance directly through the generator circuitry. Within the load coil of the RF

generator, the energy transfer between the coil and the argon creates a self-sustaining plasma. Collisions of the ions and electrons liberated from the argon ionize and excite the analyte atoms in the high-temperature plasma. The plasma operates at temperatures of 6,000 to 10,000 K, so most covalent bonds and analyte-to-analyte interactions have been eliminated.

#### ICP-AES

An inductively coupled plasma can use either an optical or a mass spectral detection system. In the former case, ICP-AES, analyte detection is achieved at an emission wavelength of the analyte in question. Because of differences in technology, a wide variety of ICP-AES systems are available, each with different capabilities, as well as different advantages and disadvantages. Simultaneous-detection systems are capable of analyzing multiple elements at the same time, thereby shortening analysis time and improving background detection and correction. Sequential systems move from one wavelength to the next to perform analyses, and often provide a larger number of analytical lines from which to choose. Array detectors, including charge-coupled devices and charge-injection devices, with detectors on a chip, make it possible to combine the advantages of both simultaneous and sequential systems. These types of detection devices are used in the most powerful spectrometers, providing rapid analysis and a wide selection of analytical lines.

The ICP can be viewed in either axial or radial (also called lateral) mode. The torch is usually positioned horizontally in axially viewed plasmas and is viewed end on, whereas it is positioned vertically in radially viewed plasmas and is viewed from the side. Axial viewing of the plasma can provide higher signal-to-noise ratios (better detection limits and precision); however, it also incurs greater matrix and spectral interferences. Methods validated on an instrument with a radial configuration will probably not be completely transferable to an instrument with an axial configuration, and vice versa.

Additionally, dual-view instrument systems are available, making it possible for the analyst to take advantage of either torch configuration. The selection of the optimal torch configuration will depend on the sample matrix, analyte in question, analytical wavelength(s) used, cost of instrumentation, required sensitivity, and type of instrumentation available in a given laboratory.

Regardless of torch configuration or detector technology, ICP-AES is a technique that provides a qualitative and/or quantitative measurement of the optical emission from excited atoms or ions at specific wavelengths. These measurements are then used to determine the analyte concentration in a given sample. Upon excitation, an atom or atomic ion emits an array of different frequencies of light that are characteristic of the distinct energy transition allowed for that element. The intensity of the light is generally proportional to the analyte concentration. It is necessary to correct for the background emission from the plasma. Sample concentration measurements are usually determined from a working curve of known standards over the concentration range of interest. It is, however, also possible to perform a single-point calibration under certain circumstances, such as with limit tests, if the methodology has been validated for sufficient specificity, sensitivity, linearity, accuracy, precision, ruggedness, and robustness.

Because there are distinct transitions between atomic energy levels, and because the atoms in an ICP are rather dilute, emission lines have narrow bandwidths. However, because the emission spectra from the ICP contain many lines, and because "wings" of these lines overlap to produce a nearly continuous background on top of the continuum that arises from the recombination of argon ions with electrons, a high-resolution spectrometer is required in ICP-AES. The decision regarding which spectral line to measure should include an evaluation of potential spectral interferences. All atoms in a sample are excited simultaneously; however, the presence of multiple elements in some samples can lead to spectral overlap.

Spectral interference can also be caused by background emission from the sample or plasma. Modern ICPs usually have background correction available, and a number of background correction techniques can be applied. Simple background correction typically involves measuring the background emission intensity at some point away from the main peak and subtracting this value from the total signal being measured. Mathematical modeling to subtract the interfering signal as a background correction can also be performed with certain types of ICP-AES spectrometers.

The selection of the analytical spectral line is critical to the success of an ICP-AES analysis, regardless of torch configuration or detector type. Though some wavelengths are preferred, the final choice must be made in the context of the sample matrix, the type of instrument being used, and the sensitivity required. Analysts might choose to start with the wavelengths recommended by the manufacturer of their particular instrument and select alternative wavelengths based on manufacturer recommendations or published wavelength tables.<sup>3,4,5,6,7</sup> Ultimately, the selection of analytical wavelengths should be demonstrated experimentally to provide sufficient specificity, sensitivity, linearity, accuracy, and precision of the analysis at hand.

Forward power, gas flow rates, viewing height, and torch position can all be optimized to provide the best signal. However, it must also be kept in mind that these same variables can influence matrix and spectral interferences.

In general, it is desirable to operate the ICP under robust conditions, which can be gauged on the basis of the MgII / MgI line pair at (280.270 nm / 285.213 nm). If that ratio of intensities is above 6.0 in an aqueous solution, the ICP is said to be robust, and is less susceptible to matrix interferences. A ratio of about 10.0 is generally what is sought. Note that the term robust conditions is unrelated to robustness as applied to analytical method validation. Operation of an instrument with an MgII / MgI ratio greater than 6.0 is not mandated, but is being suggested as a means of optimizing instrument parameters in many circumstances.

The analysis of the Group I elements can be an exception to this strategy. When atomic ions are formed from elements in this group, they assume a noble gas electron configuration, with correspondingly high excitation energy. Because the first excited state of these ions is extremely high, few are excited, so emission intensity is correspondingly low. This situation can be improved by reducing the fractional ionization, which can in turn be achieved by using lower forward power settings in combination with adjusted viewing height or nebulizer gas flow, or by adding an ionization suppression agent to the samples and standards.

When organic solvents are used, it is often necessary to use a higher forward power setting, higher intermediate and outer gas flows, and a lower nebulizer gas flow than would be employed for aqueous solutions, as well as a reduction in the nebulizer gas flow. When using organic solvents, it may also be necessary to bleed small amounts of oxygen into the torch to prevent carbon buildup in the torch.

#### Calibration

The wavelength accuracy for ICP-AES detection must comply with the manufacturer's applicable operating procedures. Because of the inherent differences among the types of instruments available, there is no general system suitability procedure that can be employed. Calibration routines recommended by the instrument manufacturer for a given ICP-AES instrument should be followed. These might include, but are not limited to, use of a multi-element wavelength calibration with a reference solution, internal mercury (Hg) wavelength calibration, and peak search. The analyst should perform system checks in accordance with the manufacturer's recommendations.

#### Standardization

The instrument must be standardized for quantification at time of use. However, because ICP-AES is a technique generally considered to be linear over a range of 6 to 8 orders of magnitude, it is not always necessary to continually demonstrate linearity by the use of a standard curve composed of multiple standards. Once a method has been developed and is in routine use, it is possible to calibrate with a blank and a single standard. One-point standardizations are suitable for conducting limit tests on production materials and final products if the methodology has been rigorously validated for sufficient specificity, sensitivity, linearity, accuracy, precision, ruggedness, and robustness. The use of a single-point standardization is also acceptable for qualitative ICP-AES analyses, where the purpose of the experiment is to confirm the presence or absence of elements without the requirement of an accurate quantification.

An appropriate blank solution and standards that bracket the expected range of the sample concentrations should be assayed and the detector response plotted as a function of analyte concentration, as in the case where the concentration of a known component is being determined within a specified tolerance. However, it is not always possible to employ a bracketing standard when an analysis is performed at or near the detection limit. This lack of use of a bracketing standard is acceptable for analyses conducted to demonstrate the absence or removal of elements below a specified limit. The number and concentrations of standard solutions used should be based on the purpose of the quantification, the analyte in question, the desired sensitivity, and the sample matrix. Regression analysis of the standard plot should be employed to evaluate the linearity of detector response, and individual monographs may set criteria for the residual error of the regression line. Optimally, a correlation coefficient of not less than 0.99, or as indicated in the individual monograph, should be demonstrated for the working curve. Here, too, however, the nature of the sample matrix, the analyte(s), the desired sensitivity, and the type of instrumentation available may dictate a correlation coefficient lower than 0.99. The analyst should use caution when proceeding with such an analysis, and should employ additional working standards.

To demonstrate the stability of the system's initial standardization, a solution used in the initial standard curve must be reassayed as a check standard at appropriate intervals throughout the analysis of the sample set. The reassayed standard should agree with its expected value to within  $\pm 10\%$ , or as specified in an individual monograph, for single-element analyses when analytical wavelengths are between 200 and 500 nm, or concentrations are  $>1 \mu\text{g per mL}$ . The reassayed standard should agree with its theoretical value to within

–20%, or as specified in an individual monograph, for multi-element analyses, when analytical wavelengths are <200 nm or >500 nm, or at concentrations of <1 µg per mL. In cases where an individual monograph provides different guidance regarding the reassayed check standard, the requirements of the monograph take precedence.

#### Procedure

Follow the procedure as directed in the individual monograph for the instrumental parameters. Because of differences in manufacturers' equipment configurations, the manufacturer's suggested default conditions may be used and modified as needed. The specification of definitive parameters in a monograph does not preclude the use of other suitable operating conditions, and adjustments of operating conditions may be necessary. Alternative conditions must be supported by suitable validation data, and the conditions in the monograph will take precedence for official purposes. Data collected from a single sample introduction are treated as a single result. This result might be the average of data collected from replicate sequential readings from a single solution introduction of the appropriate standard or sample solution. Sample concentrations are calculated versus the working curve generated by plotting the detector response versus the concentration of the analyte in the standard solutions. This calculation is often performed directly by the instrument.

#### ICP-MS

When an inductively coupled plasma uses a mass spectral detection system, the technique is referred to as inductively coupled plasma–mass spectrometry (ICP–MS). In this technique, analytes are detected directly at their atomic masses. Because these masses must be charged to be detected in ICP–MS, the method relies on the ability of the plasma source to both atomize and ionize sample constituents. As is the case with ICP–AES, a wide variety of ICP–MS instrumentation systems are available.

The systems most commonly in use are quadrupole-based systems. Gaining in interest is time-of-flight ICP–MS. Although still not in widespread use, this approach may see greater use in the future. Additionally, high-resolution sector field instruments are available.

Regardless of instrument design or configuration, ICP–MS provides both a qualitative and a quantitative measurement of the components of the sample. Ions are generated from the analyte atoms by the plasma. The analyte ions are then extracted from the atmospheric-pressure plasma through a sampling cone into a lower-pressure zone, ordinarily held at a pressure near 1 Torr. In this extraction process, the sampled plasma gases, including the analyte species, form a supersonic beam, which dictates many of the properties of the resulting analyte ions. A skimmer cone, located behind the sampling cone, "skims" the supersonic beam of ions as they emerge from the sampling cone. Behind the skimmer cone is a lower-pressure zone, often held near a milliTorr. Lastly, the skinned ions pass a third-stage orifice to enter a zone held near a microTorr, where they encounter ion optics and are passed into the mass spectrometer. The mass spectrometer separates the ions according to their mass-to-charge (m/z) ratios. The ICP–MS has a mass range up to 240 atomic mass units (amu). Depending on the equipment configuration, analyte adducts can form with diluents, with argon, or with their decomposition products. Also formed are oxides and multiply-charged analyte ions, which can increase the complexity of the resulting mass spectra. Interferences can be minimized by appropriate optimization of operational parameters, including gas flows (central, intermediate, and outer gas flow rates), sample-solution flow, RF power, extraction-lens voltage, etc., or by the use of collision or reaction cells, or cool plasma operation, if available on a given instrument. Unless a laboratory is generating or examining isotopes that do not naturally occur, a list of naturally occurring isotopes will provide the analyst with acceptable isotopes for analytical purposes. Isotopic patterns also serve as an aid to element identification and confirmation. Additionally, tables of commonly found interferences and polyatomic isobaric interferences and correction factors can be used.

ICP–MS generally offers considerably lower (better) detection limits than ICP–AES, largely because of the extremely low background that it generates. This ability is a major advantage of ICP–MS for determination of very low analyte concentrations or when elimination of matrix interferences is required. In the latter case, some interferences can be avoided simply by additional dilution of the sample solution. In some applications, analytes can be detected below the parts per trillion (ppt) level using ICP–MS. As a general rule, ICP–MS as a technique requires that samples contain significantly less total dissolved solids than does ICP–AES.

The selection of the analytical mass to use is critical to the success of an ICP–MS analysis, regardless of instrument design. Though some masses are often considered to be the primary ones, because of their high natural abundance, an alternative mass for a given element is often used to avoid spectral overlaps (isobaric interferences). Selection of an analytical mass must always be considered in the context of the sample matrix, the type of instrument being used, and the concentrations to be measured. Analysts might choose to start with masses recommended by the manufacturer of their particular instrument and select alternate masses based on manufacturer's recommendations or published tables of naturally occurring isotopes.<sup>2</sup>

Optimization of an ICP–MS method is also highly dependent on the plasma parameters and means of sample introduction. Forward power, gas flow rates, and torch position may all be optimized to provide the best signal. When organic solvents are used, it is often necessary to use a higher forward power setting and a lower nebulizer flow rate than would be used for aqueous solutions. Additionally, when organic solvents are used, it might be necessary to introduce small amounts of oxygen into the central or intermediate gas to prevent carbon buildup in the torch or on the sampler cone orifice. The use of a platinum-tipped sampling or skimmer cone may also be required in order to reduce cone degradation with some organic solvents.

#### Calibration

The mass spectral accuracy for ICP–MS detection must be in accordance with the applicable operating procedures. Because of the inherent differences between the types of instruments available, there is no general system suitability procedure that can be employed. Analysts should refer to the tests recommended by the instrument manufacturer for a given ICP–MS instrument. These may include, but are not limited to, tuning on a reference mass or masses, peak search, and mass calibration. The analyst should perform system checks recommended by the instrument manufacturer.

#### Standardization

The instrument must be standardized for quantification at the time of use. Because the response (signal vs. concentration) of ICP–MS is generally considered to be linear over a range of 6 to 8 orders of magnitude, it is not always necessary to continually demonstrate linearity by the use of a working curve. Once a method has been developed and is in routine use, it is common practice to calibrate with a blank and a single standard. One-point standardizations are suitable for conducting limit tests on production materials and final products, provided that the methodology has been rigorously validated for sufficient specificity, sensitivity, linearity, accuracy, precision, ruggedness, and robustness. An appropriate blank solution and standards that bracket the expected range of the sample concentrations should be assayed and the detector response plotted as a function of analyte concentration. The number and concentration of standard solutions used should be based on the analyte in question, the expected concentrations, and the sample matrix, and should be left to the discretion of the analyst. Optimally, a correlation coefficient of not less than 0.99, or as indicated in the individual monograph, should be demonstrated for the working standard curve. Here, too, however, the nature of the sample matrix, the analyte, the desired sensitivity, and the type of instrumentation available might dictate a correlation coefficient lower than 0.99.

The analyst should use caution when proceeding with such an analysis and should employ additional working standards.

To demonstrate the stability of the system since initial standardization, a solution used in the initial standard curve must be reassayed as a check standard at appropriate intervals throughout the analysis of the sample set. Appropriate intervals may be established as occurring after every fifth or tenth sample, or as deemed adequate by the analyst, on the basis of the analysis being performed. The reassayed standard should agree with its expected value to within  $\pm 10\%$  for single-element analyses when analytical masses are free of interferences and when concentrations are >1 ng per mL. The reassayed standard should agree with its expected value to within  $\pm 20\%$  for multi-element analyses, or when concentrations are <1 ng per mL. In cases where an individual monograph provides different guidance regarding the reassayed check standard, the requirements of the monograph take precedence.

The method of standard additions should be employed in situations where matrix interferences are expected or suspected. This method involves adding a known concentration of the analyte element to the sample solution at no fewer than two concentration levels. The instrument response is plotted against the concentration of the added analyte element, and a linear regression line is drawn through the data points. The absolute value of the x-intercept multiplied by any dilution factor is the concentration of the analyte in the sample.

#### Procedure

Follow the procedure as directed in the individual monograph for the detection mode and instrument parameters. The specification of definitive parameters in a monograph does not preclude the use of other suitable operating conditions, and adjustments of operating conditions may be necessary. Alternative conditions must be supported by suitable validation data, and the conditions in the monograph will take precedence for official purposes. Because of differences in manufacturers' equipment configurations, the analyst may wish to begin with the manufacturer's suggested default conditions and modify them as needed. Data collected from a single sample introduction are treated as a single result. Data collected from replicate sequential readings from a single introduction of the appropriate standard or sample solutions are averaged as a single result. Sample concentrations are calculated versus the working curve generated by plotting the detector response versus the concentration of the analyte in the standard solutions. With modern instruments, this calculation is often

performed by the instrument.

## GLOSSARY

AUXILIARY GAS: See Intermediate (or Auxiliary) Gas.

AXIAL VIEWING: A configuration of the plasma for AES in which the plasma is directed toward the spectrometer optical path, also called "end-on viewing."

CENTRAL (OR NEBULIZER) GAS: One of three argon gas flows in an ICP torch. The central gas is used to help create a fine mist of the sample solution when solution nebulization is employed. This fine mist is then directed through the central tube of the torch and into the plasma.

COLLISION CELL: A design feature of some ICP-MS instruments. Collision cells are used to reduce interferences from argon species or polyatomic ions and facilitate the analysis of elements that might be affected by those interferences.

COOL PLASMA: Plasma conditions used for ICP-MS that result in a plasma that is cooler than that normally used for an analysis. This condition is achieved by using a lower forward power setting and higher central-gas flow rate, and is used to help reduce isotopic interferences caused by argon and some polyatomic ions.

COOLANT GAS: See Outer (or Coolant or Plasma) Gas.

FORWARD POWER: The number of watts used to ignite and sustain the plasma during an analysis. Forward power requirements may vary, depending on sample matrix and analyte.

INTERMEDIATE (OR AUXILIARY) GAS: Gas used to "lift" the plasma off the surface of the torch, thereby preventing melting of the intermediate tube and the formation of carbon and salt deposits on the inner tube.

INTERNAL STANDARD: An element added to or present in the same concentration in blanks, standards, and samples to act as an intensity reference for the analysis. An internal standard should be used for ICP-AES work and must always be used for quantitative ICP-MS analyses.

LATERAL VIEWING: See Radial Viewing.

m: The ion mass of interest.

MULTIPLY-CHARGED IONS: Atoms that, when subjected to the high-ionization temperature of the ICP, can form doubly or triply charged ions ( $X^{++}$ ,  $X^{+++}$ , etc.). When detected by MS, the apparent mass of these ions will be  $\frac{1}{2}$  or  $\frac{1}{3}$  that of the atomic mass.

NEBULIZER: Used to form a consistent sample aerosol that mixes with the argon gas, which is subsequently sent into the ICP.

OUTER (OR COOLANT OR PLASMA) GAS: The main gas supply for the plasma.

PLASMA GAS: See Outer (or Coolant or Plasma) Gas.

RADIAL VIEWING: A configuration of the plasma for AES in which the plasma is viewed orthogonal to the spectrometer optic path. Also called "side-on viewing." See also Lateral Viewing.

REACTION CELL: Similar to Collision Cell, but operating on a different principle. Designed to reduce or eliminate spectral interferences.

SAMPLING CONE: A metal cone (usually nickel-, aluminum-, or platinum-tipped) with a small opening, through which ionized sample material flows after leaving the plasma.

SEQUENTIAL: A type of detector configuration for AES or MS in which discrete emission lines or isotopic peaks are observed by scanning or hopping across the spectral range by means of a monochromator or scanning mass spectrometer.

SIMULTANEOUS: A type of detector configuration for AES or MS in which all selected emission lines or isotopic peaks are observed at the same time by using a polychromator or simultaneous mass spectrometer, offering increased analysis speed for analyses of multi-element samples.

SKIMMER CONE: A metal cone through which ionized sample flows after leaving the sampling cone and before entering the high-vacuum region of an ICP-MS.

STANDARD ADDITIONS: A method used to determine the actual analyte concentration in a sample when viscosity or matrix effects might cause erroneous results.

TORCH: A series of three concentric tubes, usually manufactured from quartz, in which the ICP is formed.

### 731 LOSS ON DRYING

The procedure set forth in this chapter determines the amount of volatile matter of any kind that is driven off under the conditions specified. For substances appearing to contain water as the only volatile constituent, the procedure given in the chapter, [Water Determination](#) (921), is appropriate, and is specified in the individual monograph.

Mix and accurately weigh the substance to be tested, and, unless otherwise directed in the individual monograph, conduct the determination on 1 to 2 g. If the test specimen is in the form of large crystals, reduce the particle size to about 2 mm by quickly crushing. Tare a glass-stoppered, shallow weighing bottle that has been dried for 30 minutes under the same conditions to be employed in the determination. Put the test specimen in the bottle, replace the cover, and accurately weigh the bottle and the contents. By gentle, sidewise shaking, distribute the test specimen as evenly as practicable to a depth of about 5 mm generally, and not more than 10 mm in the case of bulky materials. Place the loaded bottle in the drying chamber, removing the stopper and leaving it also in the chamber. Dry the test specimen at the temperature and for the time specified in the monograph. [note—The temperature specified in the monograph is to be regarded as being within the range of  $\pm 2^{\circ}$  of the stated figure.] Upon opening the chamber, close the bottle promptly, and allow it to come to room temperature in a desiccator before weighing.

If the substance melts at a lower temperature than that specified for the determination of Loss on drying, maintain the bottle with its contents for 1 to 2 hours at a temperature  $5^{\circ}$  to  $10^{\circ}$

below the melting temperature, then dry at the specified temperature.

Where the specimen under test is Capsules, use a portion of the mixed contents of not fewer than 4 capsules.

Where the specimen under test is Tablets, use powder from not fewer than 4 tablets ground to a fine powder.

Where the individual monograph directs that loss on drying be determined by thermogravimetric analysis, a sensitive electrobalance is to be used.

Where drying in vacuum over a desiccant is directed in the individual monograph, a vacuum desiccator or a vacuum drying pistol, or other suitable vacuum drying apparatus, is to be used.

Where drying in a desiccator is specified, exercise particular care to ensure that the desiccant is kept fully effective by frequent replacement.

Where drying in a capillary-stoppered bottle\* in vacuum is directed in the individual monograph, use a bottle or tube fitted with a stopper having a  $225 \pm 25 \mu\text{m}$  diameter capillary, and maintain the heating chamber at a pressure of 5 mm or less of mercury. At the end of the heating period, admit dry air to the heating chamber, remove the bottle, and with the capillary stopper still in place allow it to cool in a desiccator before weighing.

\* Available as an "antibiotic moisture content flask" from Kontes, 1022 Spruce St., Vineland, NJ 08360-2841.

### 733 LOSS ON IGNITION

This procedure is provided for the purpose of determining the percentage of test material that is volatilized and driven off under the conditions specified. The procedure, as generally applied, is nondestructive to the substance under test; however, the substance may be converted to another form such as an anhydride.

Perform the test on finely powdered material, and break up lumps, if necessary, with the aid of a mortar and pestle before weighing the specimen. Weigh the specimen to be tested without further treatment, unless a preliminary drying at a lower temperature, or other special pretreatment, is specified in the individual monograph. Unless other equipment is designated in the individual monograph, conduct the ignition in a suitable muffle furnace or oven that is capable of maintaining a temperature within  $25^{\circ}\text{C}$  of that required for the test, and use a suitable crucible, complete with cover, previously ignited for 1 hour at the temperature specified for the test, cooled in a desiccator, and accurately weighed.

Unless otherwise directed in the individual monograph, transfer to the tared crucible an accurately weighed quantity, in g, of the substance to be tested, about equal to that calculated by the formula:

$$10 / L$$

in which L is the limit (or the mean value of the limits) for Loss on ignition, in percentage. Ignite the loaded uncovered crucible, and cover at the temperature ( $\pm 25^{\circ}\text{C}$ ) and for the period of time designated in the individual monograph. Ignite for successive 1-hour periods where ignition to constant weight is indicated. Upon completion of each ignition, cover the crucible, and allow it to cool in a desiccator to room temperature before weighing.

### 736 MASS SPECTROMETRY

A mass spectrometer produces ions from the substance under investigation, separates them according to their mass-to-charge ratio ( $m/z$ ), and records the relative abundance of each ionic species present. The instrument consists of three major components (see [Figure 1](#)):

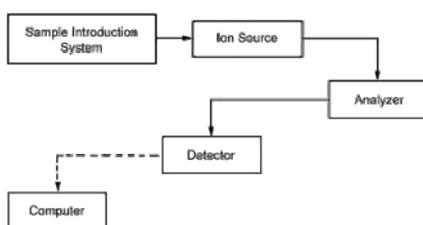

Fig. 1. Major components of a mass spectrometer.

an ion source for producing gaseous ions from the substance being studied, an analyzer for resolving the ions into their characteristic mass components according to their mass-to-charge ratios, and a detector system for detecting the ions and recording the relative abundance of each of the resolved ionic species. In addition, a sample introduction system is necessary to admit the samples to be studied to the ion source while maintaining the high vacuum requirements ( $\sim 10^{-6}$  to  $10^{-8}$  mm of mercury) of the technique; and a computer is required to control the instrument, acquire and manipulate data, and compare spectra to reference libraries.

This chapter gives an overview of the theory, construction, and use of mass spectrometers. The discussion is limited to those instruments and measurements with actual or potential application to compendial and other pharmaceutical requirements: generally, the identification and quantitation of specific compounds.

#### SAMPLE INTRODUCTION

Samples are introduced either as a gas to be ionized in the ion source, or by ejection of charged molecular species from a solid surface or solution. In some cases sample introduction and ionization take place in a single process, making a distinction between them somewhat artificial.

Substances that are gases or liquids at room temperature and atmospheric pressure can be admitted to the source as a neutral beam via a controllable leak system. Volatilizable

Compounds dissolved or adsorbed in solids or liquids can be removed and concentrated with a headspace analyzer. Vapors are flushed from the solid or liquid matrix with a stream of carrier gas and trapped on an adsorbing column. The trapped vapors are subsequently desorbed by programmed heating of the trap and introduced into the mass spectrometer by a capillary connection.

For volatilizable solids, the most frequently used method of sample introduction is the direct insertion probe. Here, the sample is placed in a small crucible at the tip of the probe, which is heated under high vacuum in close proximity to the ion source. A variation of this technique involves desorption of samples inside the ionization chamber from a rapidly heated wire or with the aid of a laser beam. Such desorption techniques, in combination with electron, chemical, or field ionization, are preferred for the analysis of heat sensitive or poorly volatile samples.

Sample introduction techniques that involve the ejection of charged molecules from the surface of solid samples include the field desorption method and various sputtering techniques, where the samples are bombarded by high energy photons, by a primary ion beam, or by a neutral particle beam. Similarly, ions can be ejected from solutions either by bombardment with a primary beam, or by one of the various spray techniques described below.

Gas and liquid chromatographs are widely used as sample inlet devices for mass spectrometers. These chromatographs provide for an initial sample purification, since only that portion of the chromatographic effluent containing the compound of interest need be admitted to the mass spectrometer. Gas chromatography/mass spectrometry (GC/MS) and liquid chromatography/mass spectrometry (LC/MS) combinations are valuable tools for the identification of unknown impurities in drugs. These combination methods have the capacity to separate complex mixtures with the opportunity to obtain structural information on the individual components.

#### Gas Chromatography/Mass Spectrometry

Gas chromatographic effluents are already in the vapor state and can be admitted directly into the mass spectrometer. Bridging the several orders of magnitude difference in the operating pressures of the two systems was initially accomplished with the use of various carrier gas separators. However, with the advent of capillary gas chromatographic columns and high capacity vacuum pumps for mass spectrometers, the gas chromatographic effluents are now fed directly into the ion source.

#### Liquid Chromatography/Mass Spectrometry

This technique is particularly useful for analyzing materials that cannot be analyzed by GC/MS, either because of thermal instability, high polarity, or high molecular weight. Compounds of biological interest such as drugs and their metabolites, polar endogenous substances, and macromolecules—including peptides, proteins, nucleic acids, and oligosaccharides—often fall into one of these categories.

Currently available LC/MS interfaces encompass a number of approaches to separating the compound of interest from the liquid chromatographic mobile phase and transforming it into an ionized species suitable for mass spectrometry. These include transport devices such as the particle beam; various spray techniques including thermospray, electrospray, and ionspray; and particle-induced desorption such as continuous-flow fast atom bombardment (CF-FAB).

#### particle beam interface

The solvent is removed from an aerosol of the liquid chromatographic effluent, and the resulting neutral analyte molecules are introduced into the ion source of the mass spectrometer where they are ionized by electron ionization (EI) or chemical ionization (CI). The resulting spectra are thus classical EI or CI spectra, the former with a wealth of structural information. There are limitations with respect to polarity, thermal lability, and molecular weight, so this technique is best suited for small organic molecules with molecular weights of less than 1000 daltons.

#### thermospray

The compound of interest in a volatile buffer mobile phase, such as ammonium acetate, is passed through heated, narrow bore tubing directly into the ion source of a mass spectrometer. The solution is vaporized in the tubing, and analyte ions desorb into the gas phase and pass into the mass analyzer. Neutral analyte molecules in the gas phase may undergo chemical ionization by reaction with gas phase buffer ions such as NH4+. Thermospray is compatible with relatively high flow rates of 1 to 2 mL per minute, solvents containing a high percentage of water, and many types of polar analytes. Thermal degradation may occur, since the analytes are exposed to relatively high temperatures during the volatilization process.

#### electrospray

The mobile phase is sprayed through a small opening (needle tip) held at a potential of several kilovolts. The charged droplets so produced are desolvated by passing through a drying gas, and the resulting ions are injected directly into the high vacuum of the analyzer through an orifice or glass capillary. Classical electrospray is limited to flow rates of 1 to 5  $\mu$ L per minute, and is therefore compatible with either microbore HPLC or post-column stream splitting techniques.

The ions may carry multiple charges, so that the  $m/z$  value of high molecular weight substances will fall into the usable range for most quadrupole or magnetic sector mass analyzers ( $m/z < 4000$ ). Analytes of up to 150,000 daltons can thus be successfully analyzed.

#### ionspray

A variant of electrospray in which nebulization with a gas flow is used to assist the formation of microdroplets of mobile phase. The technique can extend the upper limit of usable flow rates to 0.1 mL per minute. Volatile buffers must be used with both techniques.

#### desorption techniques

Microflow liquid chromatography can also be interfaced to particle induced desorption techniques such as fast atom bombardment (FAB) and liquid secondary ion mass spectroscopy (LSIMS), described in the following section on ionization techniques. Typically, column effluent flowing at a rate of 1 to 10  $\mu$ L per minute is mixed with a small percentage of nonvolatile liquid such as glycerol. The mixture is introduced via a capillary inlet onto a target within the ion source where it is bombarded with high energy (5 to 20 keV) atoms or ions. The resulting spectra are similar to FAB or LSIMS spectra but with the background from the sample matrix greatly reduced. Frit-FAB is a variant of continuous flow FAB where the sample is introduced through a porous frit target.

### IONIZATION TECHNIQUES

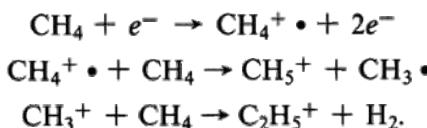

#### Electron Impact

Molecules of the sample under analysis enter the ionization chamber in the vapor state. Positive ions are produced by passing a beam of electrons, obtained from tungsten or rhenium filaments, through the vapor, which is maintained at a pressure of  $10^{-4}$  to  $10^{-6}$  mm of mercury. Provided the energy of the electron beam is greater than the ionization potential of the sample, the sample is ionized and/or fragmented, as represented by the following equation:

#### Chemical Ionization (CI)

In this process, a reagent gas at a pressure between 0.1 to 10 mm of mercury is admitted to the source and ionized by a high energy electron beam or discharge. At these pressures, ion-molecule reactions occur and the primary reagent gas ions react further. The most commonly used reagent gases are methane, isobutane, and ammonia. Typical reactions for methane are shown in the following equations:

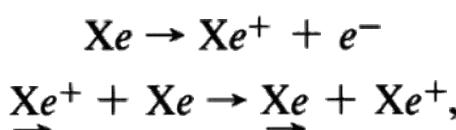

The  $\text{CH}_5^+$  species is a strong Bronsted acid and readily transfers a proton to most organic compounds

In the case of methane, the protonated ion ( $MH^+$ ) initially formed may be sufficiently energetic to dissociate further.

#### Fast Atom Bombardment (FAB)

The sample is ionized by bombardment with a beam of high speed xenon atoms, produced by exchange with highly accelerated xenon ions in a collision cell. The process is summarized as follows:

where the subscript arrows indicate the fast-moving particles.

FAB is a surface analysis technique, and care must be taken during sample preparation to optimize the condition of the surface. When the sample is coated on a probe by evaporation of a solution, the sample ion beam obtained is often transitory. Molecular adducts with alkali metals, such as ( $M + Na$ ) and ( $M + K$ ), favor ion formation. This phenomenon is used to assist in the ionization of biological molecules. Thus, treatment of the sample surface with sodium chloride solution may enhance the yield of adduct ions. Heating the sample during analysis may also increase the ion yield.

The declining yield of sample ions during analysis is probably due to destruction of the sample surface. The surface can, in effect, be continuously replaced by dissolving the sample in a suitable nonvolatile liquid and by coating the mixture onto the top of the probe. Using this approach, the lifetime of samples in the source has been extended to more than 1 hour and the range of compounds amenable to FAB analysis expanded dramatically. The long sample lifetimes and higher sensitivities so achieved make FAB an important mass spectral technique for biochemical analysis, providing the elemental formula of the sample through accurate mass determination. A further advantage of FAB, unlike CI, is the presence of fragment ions within the spectra, which aid in structural elucidation.

Recently, neutral atom bombardment has been replaced by cesium ion bombardment. Although this technique is still referred to as FAB, it is more correctly described as liquid secondary ion mass spectrometry (LSIMS).

Negative and positive ions are formed in the various ionization processes described above, and both are readily analyzed by modern mass spectrometers. Samples with a high electron capture cross section, notably those containing halide atoms, yield an abundance of negative ions. For this reason, halide derivatives of compounds to be studied are often prepared. Negative ion mass spectrometry has been successfully applied to the analysis of pesticide residues, since the structures of these compounds are well suited to the technique.

#### ANALYZERS

Mass analyzers separate the charged species in the ionized sample according to their  $m/z$  ratios, thus permitting the mass and abundance of each species to be determined. Four commonly used analyzers are the magnetic sector, the quadrupole, the time-of-flight, and the Fourier transform analyzers.

##### Magnetic Sector Analyzers

Ions generated in the ion source are collimated into a beam through the focusing action of a magnetic field and a slit assembly. After exiting the source, ions are subjected to a magnetic field perpendicular to the direction of the beam. Each ion experiences a force at right angles to both its direction of travel and the direction of the magnetic field, thereby deflecting the beam. The motion of each ion is given by

$$m/z = H^2 r^2 / 2V$$

where  $m$  is the mass in atomic mass units,  $z$  is the number of electronic charges,  $H$  is the magnetic field strength in gauss,  $r$  is the radius of the ion trajectory in centimeters, and  $V$  is the accelerating voltage. The mass spectrum is scanned by varying the strength of the magnetic field and detecting those ions passing through an exit slit as they come into "focus."

The magnetic sector mass spectrometer affords spatial resolution of ions, giving a unique trajectory at a given field strength for each value of  $m/z$ .

##### Quadrupole Analyzers

The instrument is based on four parallel rods in a square array. The ion beam is focused down the axis of the array and an electrical potential of fixed (DC) and radio frequency (RF) components is applied to diagonally opposed rods. For a given combination of DC and RF components, ions of one specific  $m/z$  ratio have a stable path down the axis. All others are deflected to the sides and lost. Mass scanning is achieved by changing the DC and RF components of the voltage, while maintaining a fixed ratio. The quadrupole analyzer is a mass filter because it separates ions on the basis of their  $m/z$  ratio.

##### Ion-trap Analyzer

This quadrupole-type device is composed of a ring electrode placed between two end cap electrodes. Depending upon the commercial version employed, the end caps are either held at ground potential or have an RF voltage applied to them, while an RF voltage is placed on the ring electrode. As a result of these potentials, the hyperbolic surfaces of the three elements form a three-dimensional quadrupole analyzer.

Both ionization and mass analysis take place within the three-dimensional quadrupole field. In the ionization step, the RF voltage on the ring electrode is set low enough so that the ions within the mass range of interest are trapped within the device. Following ionization, mass analysis is accomplished through use of the "mass selective instability" mode of operation. That is, by raising the RF voltage on the ring electrode, ions of successively higher mass are ejected from the ion trap into an electron multiplier detector. In its most common application, the ion-trap analyzer is used in conjunction with a gas chromatograph and covers the mass range of 10 to 560 daltons. However, recent advances in ion-trap technology have extended the workable mass range to many thousands of daltons.

##### Time-of-flight Analyzers

In separation is based on the principle that ions of different masses, possessing equal kinetic energy, have different velocities. If there is a fixed distance for the ions to travel, the time of travel will vary with their mass, the lighter ions traveling faster and reaching the detector in a shorter period of time. The time-of-flight is given by

$$t_f = k \sqrt{m/z}$$

where  $t_f$  is the time-of-flight in seconds. Thus, the time-of-flight of the various ions is simply proportional to the square root of the mass-to-charge ratio of the ions. To measure the time-of-flight, ions are introduced into the mass spectrometer in discrete packets so that a starting point for the timing process can be established. Ion packets are generated either through a pulsed ionization process or through a gating system in which ions are produced continuously, but are introduced only at given times into the flight tube.

#### Fourier Transform Analyzers

In a magnetic field of flux density  $B$ , ions move in circular orbits. The angular frequency,  $\omega$ , of the orbital motion is given by

$$\omega = (z/m)B$$

In this type of mass spectrometer, the orbits are varied by subjecting the ions to a resonant alternating electric field. When the frequency of the alternating field matches the orbital frequency, the ions are steadily accelerated to larger and larger orbits in coherent motion, developing a high level of kinetic energy. After the alternating electric field is turned off, the orbiting ions give rise to an alternating image current on the electrodes. A frequency analysis of this signal yields the mass of the ions involved. Thus, the Fourier transform of the time domain transient signal yields the corresponding frequency spectrum from which the mass spectrum is computed. This is a high resolution technique, yielding  $m/z$  ratios accurate to about one thousandth of a dalton.

#### TANDEM MASS SPECTROMETRY

Two mass spectrometers connected in series (MS/MS), tandem mass spectrometry, refers to the use of two or more sequential mass analysis steps. In its simplest form MS/MS (Figure 2)

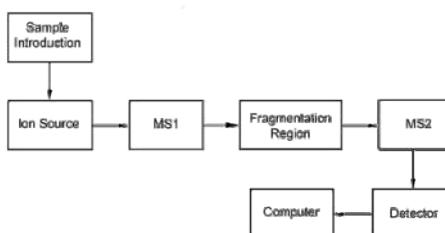

Fig. 2. Tandem Mass Spectrometry.

consists of two mass spectrometers linked in such a way that ions preselected by the first mass analyzer (MS1) are chemically or energetically modified and the results analyzed by the second mass analyzer (MS2).

The basic concept of MS/MS involves the ability to determine the mass relationship between a precursor ion in MS1 and a product ion in MS2. Different mass relationships can be probed depending on how MS1 and MS2 are scanned. These include fragmentation of a precursor and measurement of all its fragments (a product scan), selection of multiple precursors and testing for a common fragment (a precursor scan), or scanning to see if a number of precursors all lose the same neutral species (a constant neutral loss scan).

Fragmentation of the precursor ion can be induced by momentum transfer through collision with gas molecules and/or solid surfaces or by electronic excitation using lasers. These techniques are known as collision-induced dissociation, surface-induced dissociation, or laser-induced dissociation, respectively. Allowing the ion to fragment without additional activation is known as metastable decomposition.

There are many applications of MS/MS to pharmaceutical problems. Product scans can be used to obtain qualitative information from precursor ions of drug substances, impurities, and contaminants. This can aid in the identification of unknowns. The method can also be used to determine the amino acid sequence of peptides and protein fragments.

MS/MS has advantages for mixture analysis. Even when the mass spectrometer is coupled to a separation device such as a liquid or gas chromatograph, the resulting signals may be a result of overlapping or unresolved components. MS/MS can be employed to select the precursor ion from one component and obtain structural information without interference from the others.

Selected reaction monitoring is used to reduce the interference encountered during quantitative analysis for low levels of drugs in biological matrices, as in pharmacokinetic studies. If analysis is for a drug specific ion, interfering signals from other compounds in the matrix can mask the desired signal. Interference is reduced if a drug-specific fragment is selected with MS1 and a structure-specific fragment with MS2. The odds of another molecule producing the same mass relationship are diminishingly small.

MS/MS can also be used in metabolism studies to search for molecules with common structural features such as metabolites related to the drug substance. All of the metabolites might contain the same functional group that is lost as a neutral fragment. In this case a constant-neutral-loss scan will show all of these species. For instance, carboxylic acids will all lose neutral carbon dioxide. If the common functionality is lost as an ionic fragment, then a precursor scan will show all of the molecules that produce that fragment ion.

#### DATA ANALYSIS AND INTERPRETATION

The mass spectral experiment yields information on the molecular weight of ions derived from the sample and the relative abundance of each of these ions. Spectra are often complex, and not all of the ions may be separated by the mass spectrometer. The ability of the instrument to separate ions is called the resolving power, commonly described by the "10% valley" definition. This states that the resolving power is the highest mass number at which two peaks differing by one molecular weight unit and of equal height have a valley between them that is equal to 10% of the peak height. For low, medium, and high resolution mass spectrometers, this value is between 100 and 2000, 2000 and 10,000, and greater than 10,000, respectively.

If one electron is removed or added to a neutral molecule, a molecular ion of essentially the same molecular weight as the parent molecule results. It is often possible to determine the

mass of this ion with sufficient precision to enable the empirical formula of the compound to be calculated. Molecular masses may be determined accurately by using high resolution instruments or by peak-matching measurements using reference compounds.

Fragment ions are those produced from the molecular ion by various bond cleavage processes. Numerous papers in the literature relate bond cleavage patterns (fragmentation patterns) to molecular structure.

In addition to measurement of the mass of a molecular ion and its associated fragment ions, mass spectrometers are also used to quantitate compounds with a high degree of selectivity, precision, and accuracy. Compounds are introduced into the mass spectrometer either via direct insertion probe, gas inlet, or, as is more common, via gas or liquid chromatographic interfaces, which provide sample purification. Ionization may be by EI, CI, FAB, thermospray, or electrospray and mass separation by magnetic sector, quadrupole, or quadrupole ion-trap mass spectrometers. Quantitative mass spectrometry involves measuring the abundance of a specific ion, or set of ions, and relating the response to a known standard. External or internal standards may be used, but the latter are preferred for greater accuracy.

For mass spectrometry, internal standards may be either structural or stable isotope analogs. The former have the advantage of lower cost and availability while precision and accuracy are typically achieved by use of a stable isotope (2H, 13C, 15N) labeled analog of the analyte. The only requirements for labeling the analyte are that the ion monitored for the internal standard must retain an isotopic label after ionization and the label must not be exchangeable under the sampling, separation, or ionization conditions. Stable isotope internal standards are often required for acceptable quantitation, particularly with FAB and LC/MS techniques such as thermospray and electrospray.

Relative abundances of the analyte and internal standard ions are typically determined by selected ion monitoring, by which only specific ions due to the analyte and the internal standard are monitored. This technique has the advantage over scanning the full mass range in that more time is spent integrating the ion current at a selected mass-to-charge ratio, thereby increasing sensitivity. Chromatographic peak area or amount of analyte in a sample is calculated from the ratio of analyte to internal standard peak area (or height) and the regression parameters as determined by a calibration curve, using standard techniques.

### 741 MELTING RANGE OR TEMPERATURE

For Pharmacopeial purposes, the melting range, melting temperature, or melting point is defined as those points of temperature within which, or the point at which, the first detectable liquid phase is detected to the temperature at which no solid phase is apparent, except as defined otherwise for Classes II and III below. A melting transition may be instantaneous for a highly pure material, but usually a range is observed from the beginning to the end of the process. Factors influencing this transition include the sample size, the particle size, the efficiency of heat diffusion, and the heating rate, among other variables, that are controlled by procedure instructions. In some articles, the melting process is accompanied by simultaneous decomposition, which is visually evidenced as a side event like darkening of the material, charring, bubbling, or other incident. The visual impact of this side reaction frequently obscures the end of the melting process, which it may be impossible to accurately determine. In those circumstances, only the beginning of the melting can be accurately established; and it is to be reported as the melting temperature. The accuracy of the apparatus to be used as described below should be checked at suitable intervals by the use of one or more of the six USP Melting Point Reference Standards, preferably those that melt nearest the melting temperatures of the compounds being tested (see [USP Reference Standards](#) (11)).

Five procedures for the determination of melting range or temperature are given herein, varying in accordance with the nature of the substance. When no class is designated in the monograph, use the procedure for Class Ia for crystalline or amorphous substances and the procedure for Class II for waxy substances.

The procedure known as the mixed-melting point determination, whereby the melting range or temperature of a solid under test is compared with that of an intimate mixture of equal parts of the solid and an authentic specimen of it, e.g., the corresponding USP Reference Standard, if available, may be used as a confirmatory identification test. Agreement of the observations on the original and the mixture constitutes reliable evidence of chemical identity.

Apparatus I—An example of a suitable melting range Apparatus I consists of a glass container for a bath of transparent fluid, a suitable stirring device, an accurate thermometer (see [Thermometers](#) (21)); and a controlled source of heat. The bath fluid is selected with a view to the temperature required, but light paraffin is used generally and certain liquid silicones are well adapted to the higher temperature ranges. The fluid is deep enough to permit immersion of the thermometer to its specified immersion depth so that the bulb is still about 2 cm above the bottom of the bath. The heat may be supplied by an open flame or electrically. The capillary tube is about 10 cm long and 0.8 to 1.2 mm in internal diameter with walls 0.2 to 0.3 mm in thickness.

Apparatus II—An instrument may be used in the procedures for Classes I, Ia, and Ib. An example of a suitable melting range Apparatus II consists of a block of metal that may be heated at a controlled rate, its temperature being monitored by a sensor. The block accommodates the capillary tube containing the test substance and permits monitoring of the melting process, typically by means of a beam of light and a detector. The detector signal may be processed by a microcomputer to determine and display the melting point or range, or the detector signal may be plotted to allow visual estimation of the melting point or range.

Procedure for Class I, Apparatus I—Reduce the substance under test to a very fine powder, and, unless otherwise directed, render it anhydrous when it contains water of hydration by drying it at the temperature specified in the monograph, or, when the substance contains no water of hydration, dry it over a suitable desiccant for not less than 16 hours.

Charge a capillary glass tube, one end of which is sealed, with a sufficient amount of the dry powder to form a column in the bottom of the tube 2.5 to 3.5 mm high when packed down as closely as possible by moderate tapping on a solid surface.

Heat the bath until the temperature is about 30° below the expected melting point. Remove the thermometer, and quickly attach the capillary tube to the thermometer by wetting both with a drop of the liquid of the bath or otherwise, and adjust its height so that the material in the capillary is level with the thermometer bulb. Replace the thermometer, and continue the heating, with constant stirring, sufficiently to cause the temperature to rise at a rate of about 3° per minute. When the temperature is about 3° below the lower limit of the expected melting range, reduce the heating so that the temperature rises at a rate of about 1° to 2° per minute. Continue heating until melting is complete.

The temperature at which the column of the substance under test is observed to collapse definitely against the side of the tube at any point indicates the beginning of melting, and the temperature at which the test substance becomes liquid throughout corresponds to the end of melting or the melting point. The two temperatures fall within the limits of the melting range. If melting occurs with decomposition, the melting temperature corresponding to the beginning of the melting is within the range specified.

Procedure for Class Ia, Apparatus I—Prepare the test substance and charge the capillary as directed for Class I, Apparatus I. Heat the bath until the temperature is about 10° below the expected melting point and is rising at a rate of  $1 \pm 0.5$ ° per minute. Insert the capillary as directed under Class I, Apparatus I when the temperature is about 5° below the lower limit of the expected melting range, and continue heating until melting is complete. Record the melting range as directed for Class I, Apparatus I.

Procedure for Class Ib, Apparatus I—Place the test substance in a closed container and cool to 10°, or lower, for at least 2 hours. Without previous powdering, charge the cooled material into the capillary tube as directed for Class I, Apparatus I, then immediately place the charged tube in a vacuum desiccator and dry at a pressure not exceeding 20 mm of mercury for 3 hours. Immediately upon removal from the desiccator, fire-seal the open end of the tube, and as soon as practicable proceed with the determination of the melting range

as follows: Heat the bath until a temperature  $10 \pm 1^\circ$  below the expected melting range is reached, then introduce the charged tube, and heat at a rate of rise of  $3 \pm 0.5^\circ$  per minute until melting is complete. Record the melting range as directed for Class I, Apparatus I.

If the particle size of the material is too large for the capillary, pre-cool the test substance as above directed, then with as little pressure as possible gently crush the particles to fit the capillary, and immediately charge the tube.

Procedure for Class I, Apparatus II— Prepare the substance under test and charge the capillary tube as directed for Class I, Apparatus I. Operate the apparatus according to the manufacturer's instructions. Heat the block until the temperature is about  $30^\circ$  below the expected melting point. Insert the capillary tube into the heating block, and continue heating at a rate of temperature increase of about  $1^\circ$  to  $2^\circ$  per minute until melting is complete.

The temperature at which the detector signal first leaves its initial value indicates the beginning of melting, and the temperature at which the detector signal reaches its final value corresponds to the end of melting, or the melting point. The two temperatures fall within the limits of the melting range. In the event of dispute, only the melting range or temperature obtained as directed for Class I, Apparatus I, is definitive. If melting occurs with decomposition, the melting temperature corresponding to the beginning of the melting is within the range specified. In the event of dispute, only the melting range or temperature obtained as directed for Class I, Apparatus I, is definitive.

Procedure for Class II— Carefully melt the material to be tested at as low a temperature as possible, and draw it into a capillary tube, which is left open at both ends, to a depth of about 10 mm. Cool the charged tube at  $10^\circ$ , or lower, for 24 hours, or in contact with ice for at least 2 hours. Then attach the tube to the thermometer by suitable means, adjust it in a water bath so that the upper edge of the material is 10 mm below the water level, and heat as directed for Class I, Apparatus I except, within  $5^\circ$  of the expected melting temperature, to regulate the rate of rise of temperature to  $0.5^\circ$  to  $1.0^\circ$  per minute. The temperature at which the material is observed to rise in the capillary tube is the melting temperature.

Procedure for Class III— Melt a quantity of the test substance slowly, while stirring, until it reaches a temperature of  $90^\circ$  to  $92^\circ$ . Remove the source of the heat and allow the molten substance to cool to a temperature of  $8^\circ$  to  $10^\circ$  above the expected melting point. Chill the bulb of a suitable thermometer (see [Thermometers](#) 21) to  $5^\circ$ , wipe it dry, and while it is still cold dip it into the molten substance so that approximately the lower half of the bulb is submerged. Withdraw it immediately, and hold it vertically away from the heat until the wax surface dulls, then dip it for 5 minutes into a water bath having a temperature not higher than  $16^\circ$ .

Fix the thermometer securely in a test tube so that the lower point is 15 mm above the bottom of the test tube. Suspend the test tube in a water bath adjusted to about  $16^\circ$ , and raise the temperature of the bath at the rate of  $2^\circ$  per minute to  $30^\circ$ , then change to a rate of  $1^\circ$  per minute, and note the temperature at which the first drop of melted substance leaves the thermometer. Repeat the determination twice on a freshly melted portion of the test substance. If the variation of three determinations is less than  $1^\circ$ , take the average of the three as the melting point. If the variation of three determinations is  $1^\circ$  or greater than  $1^\circ$ , make two additional determinations and take the average of the five.

#### 751 METAL PARTICLES IN OPHTHALMIC OINTMENTS

The following test is designed to limit to a level considered to be unobjectionable the number and size of discrete metal particles that may occur in ophthalmic ointments.

Procedure— Extrude, as completely as practicable, the contents of 10 tubes individually into separate, clear, flat-bottom, 60-mm Petri dishes that are free from scratches. Cover the dishes, and heat at  $85^\circ$  for 2 hours, increasing the temperature slightly if necessary to ensure that a fully fluid state is obtained. Taking precautions against disturbing the melted sample, allow each to cool to room temperature and to solidify.

Remove the covers, and invert each Petri dish on the stage of a suitable microscope adjusted to furnish 30 times magnification and equipped with an eye-piece micrometer disk that has been calibrated at the magnification being used. In addition to the usual source of light, direct an illuminator from above the ointment at a  $45^\circ$  angle. Examine the entire bottom of the Petri dish for metal particles. Varying the intensity of the illuminator from above allows such metal particles to be recognized by their characteristic reflection of light.

Count the number of metal particles that are  $50 \mu\text{m}$  or larger in any dimension: the requirements are met if the total number of such particles in all 10 tubes does not exceed 50, and if not more than 1 tube is found to contain more than 8 such particles. If these results are not obtained, repeat the test on 20 additional tubes: the requirements are met if the total number of metal particles that are  $50 \mu\text{m}$  or larger in any dimension does not exceed 150 in all 30 tubes tested, and if not more than 3 of the tubes are found to contain more than 8 such particles each.

#### 755 MINIMUM FILL

The following tests and specifications apply to articles such as creams, gels, jellies, lotions, ointments, pastes, powders, and aerosols, including pressurized and nonpressurized topical sprays that are packaged in containers in which the labeled content is not more than 150 g or 150 mL.

PROCEDURE FOR DOSAGE FORMS OTHER THAN AEROSOLS— For containers labeled by weight, select a sample of 10 filled containers, and remove any labeling that might be altered in weight during the removal of the container contents. Thoroughly cleanse and dry the outside of the containers by a suitable means, and weigh individually. Quantitatively remove the contents from each container, cutting the latter open and washing with a suitable solvent, if necessary, taking care to retain the closure and other parts of each container. Dry, and again weigh each empty container together with its corresponding parts. The difference between the two weights is the net weight of the contents of the container. For containers labeled by volume, pour the contents of 10 containers into 10 suitable graduated cylinders, and allow to drain completely. Record the volume of the contents of each of the 10 containers. The average net content of the 10 containers is not less than the labeled amount, and the net content of any single container is not less than 90% of the labeled amount where the labeled amount is 60 g or 60 mL or less, or not less than 95% of the labeled amount where the labeled amount is more than 60 g or 60 mL but not more than 150 g or 150 mL. If this requirement is not met, determine the content of 20 additional containers. The average content of the 30 containers is not less than the labeled amount, and the net content of not more than 1 of the 30 containers is less than 90% of the labeled amount where the labeled amount is 60 g or 60 mL or less, or less than 95% of the labeled amount where the

labeled amount is more than 60 g or 60 mL but not more than 150 g or 150 mL.

PROCEDURE FOR AEROSOLS— Select a sample of 10 filled containers, and remove any labeling that might be altered in weight during the removal of the container contents. Thoroughly cleanse and dry the outsides of the containers by suitable means, and weigh individually. Remove the contents from each container by employing any safe technique (e.g., chill to reduce the internal pressure, remove the valve, and pour). Remove any residual contents with suitable solvents, then rinse with a few portions of methanol. Retain as a unit the container, the valve, and all associated parts, and heat them at 100° for 5 minutes. Cool, and again weigh each of the containers together with its corresponding parts. The difference between the original weight and the weight of the empty aerosol container is the net fill weight. Determine the net fill weight for each container tested. The requirements are met if the net weight of the contents of each of the 10 containers is not less than the labeled amount.

### 761 NUCLEAR MAGNETIC RESONANCE

Nuclear magnetic resonance (NMR) spectroscopy is an analytical procedure based on the magnetic properties of certain atomic nuclei. It is similar to other types of spectroscopy in that absorption or emission of electromagnetic energy at characteristic frequencies provides analytical information. NMR differs in that the discrete energy levels between which the transitions take place are created artificially by placing the nuclei in a magnetic field.

Atomic nuclei are charged and behave as if they were spinning on the nuclear axis, thus creating a magnetic dipole of moment  $\mu$  along this axis. The angular momentum of the spinning nucleus is characterized by a spin quantum number ( $I$ ). If the mass number is odd,  $I$  is  $1/2$  or an integer plus  $1/2$ ; otherwise, it has a value of 0 or a whole number.

Nuclei having a spin quantum number,  $I \neq 0$ , when placed in an external uniform static magnetic field of strength,  $H_0$ , align with respect to the field in  $(2I + 1)$  possible orientations. Thus, for nuclei with  $I = 1/2$ , which include most isotopes of analytical significance ([Table 1](#)), there are two possible orientations, corresponding to two different energy states. A nuclear resonance is the transition between these states, by absorption or emission of the corresponding amount of energy. In a static magnetic field the nuclear magnetic axis precesses (Larmor precession) about the external field axis. The precessional angular velocity,  $\omega_0$ , is related to the external magnetic field strength through the equation:

$$\omega_0 = \gamma H_0$$

in which  $\gamma$  is the magnetogyric ratio and is a constant for all nuclei of a given isotope. If energy from an oscillating radio-frequency field is introduced, the absorption of radiation takes place according to the relationship:

$$\Delta E = h\nu = \mu H_0 / I$$

where  $h$  is Planck's constant, and

$$\nu = \omega_0 / 2\pi = \gamma H_0 / 2\pi$$

Thus, when the frequency ( $\nu$ ) of the external energy field ( $E = h\nu$ ) is the same as the precessional angular velocity, resonance is achieved.

Table 1. Properties of Some Nuclei Amenable to NMR Study

Nucleus	I	Natural Abundance, %	Sensitivity	Resonance Frequency (MHz) at		
				1.4093 T*	2.3488 T	4.6975 T
1H	1/2	99.98	1.00	60.000	100.000	200.000
13C	1/2	1.108	0.0159	15.087	25.144	50.288
19F	1/2	100	0.83	56.446	94.077	188.154
31P	1/2	100	0.0663	24.289	40.481	80.961
11B	(3/2)	80.42	0.17	19.250	32.084	64.167

\* T = tesla: 1.4093 T = 14.093 kilogauss.

The energy difference between the two levels corresponds to electromagnetic radiation in the radio-frequency range. It is a function of  $\gamma$ , which is a property of the nucleus, and  $H_0$ , the external field strength. As shown in [Table 1](#), the resonance frequency of a nucleus increases with the increase of the magnetic field strength.

NMR is a technique of high specificity but relatively low sensitivity. The basic reason for the low sensitivity is the comparatively small difference in energy between the excited and the ground states (0.02 calories at 15 to 20 kilogauss field strength), which results in a population difference between the two levels of only a few parts per million. Another important aspect of the NMR phenomenon, with negative effects on the sensitivity, is the long lifetime of most nuclei in the excited state, which affects the design of the NMR analytical test, especially in pulsed repetitive experiments. Simultaneous acquisition of the entire spectrum instead of frequency-swept spectra can give sensitivity enhancement.

#### Apparatus

The distinctive components of an NMR spectrometer are a magnet and a source of radio frequency. The instruments are described by the approximate resonance frequency of the analytical nucleus, e.g., 1H NMR. More recently, instruments are being referred to by their field strengths. Some spectrometers are dedicated to the analysis of one type of nucleus; others are designed to obtain spectra of different nuclei.

There are two types of commercial NMR spectrometers: the classical continuous wave (CW) instruments and the more modern pulse Fourier-transform (FT) instruments. The CW spectrometers use a technique similar to that of classical optical spectrometers: a slow scan of radio frequency (at fixed magnetic field) or of the magnetic field (at fixed radio frequency) over a domain corresponding to the resonance of the nuclei being studied. The signal generated by the absorption of energy is detected, amplified, and recorded.

Various instrument configurations are possible. The arrangement of a typical double-coil spectrometer, as one might see in the lower resolution 60-MHz and 100-MHz CW instruments, is illustrated in [Figure 1](#).

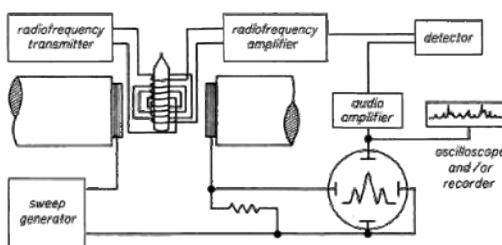

Fig. 1. Block diagram of a typical NMR spectrometer.

The limitations of the CW spectrometers are low sensitivity and long analysis time. In pulsed NMR spectrometers, a single pulse of radio frequency energy is used to simultaneously activate all nuclei. The excited nuclei returning to the lower energy level generate a free induction decay (FID) signal that contains in a time domain all the information obtained in a frequency domain with a CW spectrometer. The time domain and the frequency domain responses form a pair of FTs; the mathematical operation is performed by a computer after analog-to-digital conversion. After a delay allowing for relaxation of the excited nuclei, the pulse experiment (transient) may be repeated and the response coherently added in the computer memory, with random noise being averaged out. (A similar signal-to-noise increase can be obtained by combining CW spectrometers with computers that average transients.)

The block diagram of a typical high-resolution pulsed spectrometer is shown in [Figure 2](#).

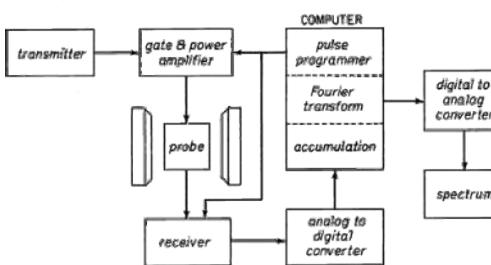

Fig. 2. Block diagram of a typical pulsed FT-NMR spectrometer.

It is a typical configuration of the high-resolution spectrometer that uses a superconducting (cryogenic) solenoid as the source of the magnetic field. Introduction of the pulsed NMR spectrometer has made the acquisition of spectra of many nuclei, other than protons, routine. It has also allowed proton spectra to be obtained in much less time, and with smaller amounts of specimen, as compared to CW techniques.

NMR spectrometers have strict stability and homogeneity requirements. Stability is often achieved by a field-frequency locking system that "locks" the magnetic field to the resonance frequency of a reference signal. The lock signal can be homonuclear or heteronuclear. In the latter case, the reference resonance is usually a deuterium signal from a deuterated solvent. On older spectrometers, using deuterium as a locking nucleus permits noise decoupling of protons to be carried out while studying nuclei like  $^{13}\text{C}$ . While internal homonuclear locks are still used in CW proton spectrometers (where tetramethylsilane at about 0.5% provides a convenient lock), they are hardly ever used in pulsed FT spectrometers.

No type of magnet is capable of producing a homogeneous field over the space occupied by the specimen. Two techniques are usually employed to compensate for this lack of homogeneity: specimen spinning and the use of additional (shim) coils. Because of design, particularly probe design, the spinning in the case of the electromagnet or permanent magnet is perpendicular to the basic field. In the superconducting magnet, the axis of rotation can only be parallel to the basic magnetic field. The spin rate should be sufficient to produce averaging of the field, but not fast enough to produce an extended vortex in the specimen tube. A vortex extended near the region exposed to the radio-frequency coils decreases resolution. The shim coils are adjusted by the operator until instrumental contributions to the observed line width are minimized.

An electronic integrator is a feature of most NMR spectrometers. On a CW instrument (1H and 19F) the integrator, connected to the spectrometer output stage, determines the relative areas of the resonance peaks and presents these areas as a series of stepped horizontal lines when a sweep is made in the integration mode. On FT-NMR spectrometers, an integration algorithm is included in the spectrometer software, and the resonance peak areas may be presented graphically as stepped lines or tabulated as numeric values. The use of computer-generated tabulated/numeric integration data should not be accepted without a specific demonstration of precision and accuracy on the spectrometer in question.

#### The Spectrum

The signals (peaks) in an NMR spectrum are characterized by four attributes: resonance frequency, multiplicity, line width, and relative intensity. The analytical usefulness of the NMR technique resides in the fact that the same types of nuclei, when located in different molecular environments, exhibit different resonance frequencies. The reason for this difference is that the effective field experienced by a particular nucleus is a composite of the external field provided by the instrument and the field generated by the circulation of the surrounding electrons. (The latter is generally opposed to the external field and the phenomenon is called "shielding.") In contrast with other spectroscopic methods, it is not possible to measure accurately the absolute values of transition frequencies. However, it is possible to measure accurately the difference in frequencies between two resonance signals. The position of a signal in an NMR spectrum is described by its separation from another resonance signal arbitrarily taken as standard. This separation is called chemical shift.

The chemical shift, being the difference between two resonance frequencies, is directly proportional to the magnetic field strength (or to the frequency of the oscillator). However, the ratio between the chemical shift, in frequency units, and the instrument frequency is constant. This allows definition of a dimensionless chemical shift parameter ( $\delta$ ) that is independent of the instrument frequency:

$$\delta = \frac{(\nu_s - \nu_r)}{\nu_o} + \delta_r$$

in which  $\nu_s$  is the test substance line frequency,  $\nu_r$  is the reference line frequency,  $\nu_o$  is the instrument frequency, in mHz, and  $\delta_r$  is the chemical shift of the reference.

By employing the above equation, it is possible to use (with appropriate caution) the chemical shift of any known species (such as the residual  $^1\text{H}$ -containing species in deuterated solvent) as a chemical shift reference. The above equation, now in common use, is applicable to nearly all methods except in the relatively rare cases where extremely precise chemical shift values must be determined, and is readily adaptable to nuclei where non-zero reference standards are the only practical method of chemical shift determinations.

For CW instruments, tetramethylsilane (TMS) is the most widely used chemical shift reference for proton and carbon spectra. It is chemically inert, exhibits only one line, which is at a higher field than most signals, and is volatile, thus allowing for ready specimen recovery. Sodium 3-(trimethylsilyl)propionate (TSP) or sodium 2,2-dimethyl-2-silapentane-5-sulfonate (DSS) are used as NMR references for aqueous solutions. The resonance frequency of the TSP or DSS methyl groups closely approximate that of the TMS signal; however, DSS has the disadvantage of showing a number of methylene multiplets that may interfere with signals from the test substance. Where the use of an internal NMR reference material is not desirable, an external reference may be used.

Conventional NMR spectra are shown with the magnetic field strength increasing from left to right. Nuclei that resonate at high magnetic field strengths (to the right) are said to be more shielded (greater electron density) than those that resonate at lower magnetic field strengths: these are said to be de-shielded (lower electron density).

[Figure 3](#) shows the proton NMR spectrum of 2,3-dimethyl-2-butene methyl ether. This compound contains protons in a methylene group (marked d in the graphic formula) and in four methyl groups (a, a, b, and c). Methyl groups b and c are situated in distinctly different molecular environments than the two a methyl groups. Three different methyl proton resonances are observed as spectral peaks in addition to the peak corresponding to methylene proton resonance. The two a methyl groups, being in very similar environments, have the same chemical shift. Interaction between magnetically active nuclei situated within a few bond lengths of each other leads to coupling, which results in a mutual splitting of the respective signals into sets of peaks or multiplets.

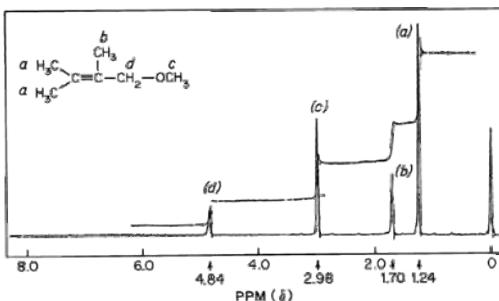

Fig. 3. NMR spectrum of 2,3-dimethyl-2-butene methyl ether (15% in  $\text{CCl}_4$ ) showing four nonequivalent, apparently uncoupled protons with a normal integral trace (peak area ratio from low H0 to high H0 of 2:3:3:6). (Tetramethylsilane, the NMR Reference, appears at 0 ppm.) The system of units represented by  $\delta$  is defined under The Spectrum, in this chapter.

The coupling between two nuclei may be described in terms of the spin-spin coupling constant,  $J$ , which is the separation (in hertz) between the individual peaks of the multiplet. Where two nuclei interact and cause reciprocal splitting, the measured coupling constants in the two resulting multiplets are equal. Furthermore,  $J$  is independent of magnetic field strength.

In a first-order, comparatively noncomplex spin system, the number of individual peaks that are expected to be present in a multiplet and the relative peak intensities are predictable. The number of peaks is determined by  $2n + 1$ , where  $n$  is the number of nuclei in adjacent groups that are active in splitting. For protons this becomes  $(n + 1)$  peaks. In general, the relative intensity of each peak in the multiplet follows the coefficient of the binomial expansion  $(a + b)^n$ . These coefficients may conveniently be found by use of Pascal's triangle, which produces the following relative areas for the specified multiplets: doublet, 1:1; triplet, 1:2:1; quartet, 1:3:3:1; quintet, 1:4:6:4:1; sextet, 1:5:10:10:5:1; and septet, 1:6:15:20:15:6:1. This orderly arrangement, generally referred to as first-order behavior, may be expected when the ratio of  $\Delta\delta$  to  $J$  is greater than about 10;  $\Delta\delta$  is the chemical shift difference between two nuclei or two groups of equivalent nuclei. Two examples of idealized spectra arising from first-order coupling are shown in [Figure 4](#).

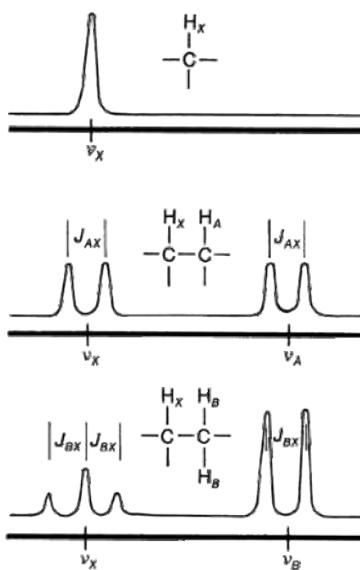

Fig. 4. Diagrammatic representation of simple first-order coupling of adjacent protons.

[Figure 5](#) shows a spectrum displaying triplet signals resulting from the mutual splitting of two adjacent methylene groups.

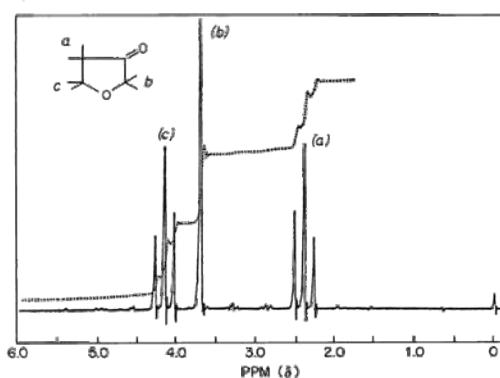

Fig. 5. NMR spectrum of 3-keto-tetrahydrofuran (10% in  $\text{CCl}_4$ ) showing three nonequivalent protons, with a normal integral trace (peak area ratio from low  $\text{H}_0$  to high  $\text{H}_0$  of 1:1:1). Note two sets of methylene groups coupled to each other at 4.2 and 2.4 ppm. (Tetramethylsilane, the NMR Reference, appears at 0 ppm.)

Coupling may occur between  $1\text{H}$  and other nuclei, such as  $19\text{F}$ ,  $13\text{C}$ , and  $31\text{P}$ . In some cases, e.g., in the CW mode, the coupling constants may be large enough so that part of the multiplet is off scale at either the upfield or downfield end. This type of coupling may occur over the normal “three-bond distance,” as for  $1\text{H}$ - $1\text{H}$  coupling.

Magnetically active nuclei with  $I \geq 1$ , such as  $14\text{N}$ , possess an electrical quadrupole moment, which produces line-broadening of the signal due to neighboring nuclei.

Another characteristic of the signal, its relative intensity, has wide analytical applications. In carefully designed experiments (see the section General Method), the area or intensity of a signal is directly proportional to the number of protons giving rise to the signal. As a result, it is possible to determine the relative ratio of the different kinds of protons or other nuclei in a specimen or to perform NMR assays with the aid of an internal standard.

The NMR spectra may contain extraneous signals due to the inhomogeneity of the magnetic field throughout the specimen. These artifacts, called spinning side bands, appear as minor lines symmetrically located around each signal. The presence of large spinning side bands indicates that the non-spinning shims require adjustment. The separation is equal to the frequency of the specimen tube spin rate or some integral multiple of that frequency. Thus, spinning side bands are readily identifiable.

#### General Method

Inadequate specimen preparation or incorrect instrumental adjustments and parameters may lead to poor resolution, decreased sensitivity, spectral artifacts, and erroneous data. It is preferable that the operator be familiar with the basic theory of NMR, the properties of the specimen, and the operating principles of the instruments. Strict adherence to the instruction manuals provided by the manufacturer and frequent checks of the performance of the instrument are essential.

The method and procedures discussed here refer specifically to  $1\text{H}$  (proton) and  $19\text{F}$  NMR. They are applicable, with modification, to other nuclei. The discussion presumes that the NMR spectra are obtained from liquid test substances or solutions in suitable solvents.

**Selection of Solvent**— In addition to having good solubility properties, suitable solvents do not exhibit resonance peaks that obscure resonance peaks of the specimen being analyzed. The most commonly used solvents for proton and carbon NMR are listed in Table 2. Deuterated solvents also provide the signal for the heteronuclear system lock. If solvent peaks might interfere with any signals from the specimen, then the isotopic purity of the solvent should be as high as possible. Deuterium ( $I = 1$ ) does not exhibit resonance under  $1\text{H}$  conditions but may cause  $J$ -coupling to be observed. The residual protons generate solvent peaks whose chemical shifts are shown in Table 2.

Table 2. Solvents Commonly Used for Proton NMR

Solvent	Residual Proton Signal, $\delta$ <sup>a</sup>
$\text{CCl}_4$ <sup>b</sup>	—
$\text{CS}_2$ <sup>b</sup>	—
$\text{SO}_2$ (liquid)	—
$(\text{CF}_3)_2\text{CO}$	—
$\text{CDCl}_3$	7.27
$\text{CD}_3\text{OD}$	3.35, 4.8 <sup>c</sup>
$(\text{CD}_3)_2\text{CO}$	2.05
$\text{D}_2\text{O}$	4.7 <sup>c</sup>
$\text{DMSO-d}_6$ <sup>d</sup>	2.50
$\text{C}_6\text{D}_6$	7.20
p-Dioxane-d <sub>8</sub>	3.55
$\text{CD}_3\text{CO}_2\text{D}$	2.05, 8.5 <sup>c</sup>
$\text{DMF-d}_7$ <sup>e</sup>	2.77, 2.93, 8.05

<sup>a</sup>  $\delta$  in ppm relative to tetramethylsilane arbitrarily taken as 0 $\delta$  or 0 ppm.

<sup>b</sup> Spectrophotometric grade.

<sup>c</sup> Highly variable; depends on solute and temperature.

<sup>d</sup> Dimethyl sulfoxide-d<sub>6</sub>.

<sup>e</sup> N,N-Dimethylformamide-d<sub>7</sub> per Aldrich, Alfa, Fluka, and Sigma catalogs.

Some solvents (e.g.,  $\text{D}_2\text{O}$  or  $\text{CD}_3\text{OD}$ ) enter into fast exchange reactions with protons and may eliminate resonance signals from  $-\text{COOH}$ ,  $-\text{OH}$ , and  $-\text{NH}_2$  structural groups. The protons in alcohols and amines do not take part in rapid exchange unless catalyzed by small concentrations of acid or base, except in the presence of  $\text{D}_2\text{O}$  and some other solvents (e.g.,  $\text{CD}_3\text{OD}$ ).

For  $19\text{F}$  NMR, most solvents used in proton NMR may be employed, the most common ones being  $\text{CHCl}_3$ ,  $\text{CCl}_4$ ,  $\text{H}_2\text{O}$ ,  $\text{CS}_2$ , aqueous acids and bases, and dimethylacetamide. In general, any nonfluorinated solvent may be used, provided that it is of spectral quality. Obviously, there is no interference from the protonated functional groups of the solvent. However, unless they are decoupled, protonated functional groups on the  $19\text{F}$ -containing specimen will provide  $J$ -coupling.

**Specimen Preparation**— Directions are usually given in individual monographs. The solute concentration depends on the objective of the experiment and on the type of instrument. Detection of minor contaminants may require higher concentrations. The solutions are prepared in separate vials and transferred to the NMR specimen tube. The volume required depends on the size of the specimen tube and on the geometry of the instrument. The level of the solution in the tube must be high enough to extend beyond the coils when the tube is

inserted in the instrument probe and spun.

The NMR specimen tubes must meet narrow tolerance specifications in diameter, wall thickness, concentricity, and camber. The most widely used tubes have a 5- or 10-mm outside diameter and a length of between 15 and 20 cm. Microtubes are available for the analysis of small amounts of specimen.

Procedure— The specimen tube is placed in a probe located in the magnetic field. The probe contains electronic circuitry including the radio-frequency coil(s), and is provided with attachments for the air supply that spins the specimen tubes.

Instrument adjustments are made before each experiment. The spinning rate of the specimen tube is adjusted so that spinning side bands do not interfere with the peaks of interest and the vortex does not extend beyond the coils in the probe. To optimize the instrument performance, the magnetic shim gradients on FT-NMR spectrometers are adjusted. In adjusting resolution on CW spectrometers, a good indicator is the definite "ringing" of the TMS peak. The phenomenon of ringing is the oscillation of the recorder trace after the magnetic field has passed through a resonance frequency. Ringing, evident on a number of the peaks in Figures 5 and 6, arises during rapid scans and decays exponentially to the baseline value.

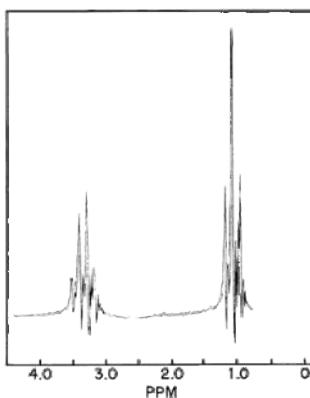

Fig. 6. Continuous wave proton spectrum of ethyl ether.

Figure 7 clearly indicates the absence, in an FT experiment, of the ringing phenomenon. Ringing will not appear because the spectrum obtained is the result of analysis of the FID by Fourier transformation and not a magnetic field or frequency sweep through the individual resonance positions.

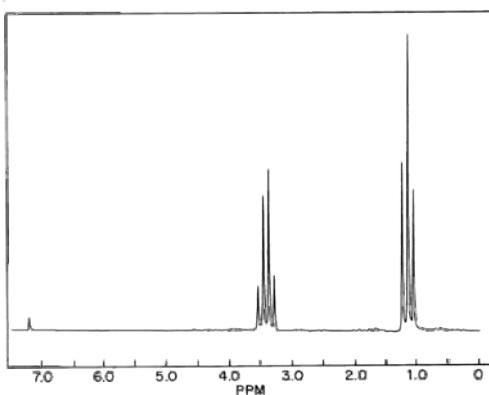

Fig. 7. Proton NMR spectrum of ethyl ether in deuterated chloroform.

With proton CW instruments the spectrum is scanned from 0 ppm to about 10 ppm with a scan time of about 1 to 5 minutes. The amplification is adjusted so that all peaks remain on scale. If the response is low at reasonable amplitude, the radio-frequency power is increased to obtain the highest possible peak response without peak broadening. After the initial scan, the presence of peaks downfield of 10 ppm is quickly checked by off-setting the instrument response by about 5 ppm. With CW instrumentation, it is common for the TMS peak to shift slightly during an extended scan. The extent of the shift is usually obtained by comparing the relative positions of another peak in the initial scan with the same peak in the offset scan.

The operation of an FT-NMR spectrometer is a much more elaborate experiment. The computer serves to control the spectrometer, to program the experiment, and to store and process the data. Programming the experiment involves setting values for a large number of variables including the spectral width to be examined, the duration ("width") of the excitation pulse, the time interval over which data will be acquired, the number of transients to be accumulated, and the delay between one acquisition and the next. The analysis time for one transient is in the order of seconds. The number of transients is a function of the specimen concentration, the type of nucleus, and the objective of the experiment. At the end of the experiment, the FID signal is stored in digitized form in the computer memory and is displayed on the video screen. The signal can be processed mathematically to enhance either the resolution or the sensitivity, and it can be Fourier-transformed into a frequency-domain spectrum. The instrument provides a plot of the spectrum. The integration routine, accessed through keyboard commands, results in a stepped-line plot. Considerably more accurate integrals are obtained if the signals or regions of interest are separately integrated.

FT-NMR spectrometers may yield qualitative and quantitative data from the same experiment, but this is seldom done in practice. In quantitative FT experiments, special precautions must be taken for the signal areas to be proportional to the number of protons. The delays between pulses must be long enough to allow complete relaxation of all excited nuclei. This results in a considerable increase in analysis time and in some loss of resolution. Qualitative analysis is usually performed in nonquantitative conditions, with the design of the experiment directed to fast analysis with maximum resolution or sensitivity.

#### Qualitative and Quantitative Analysis

NMR spectroscopy has been used for a wide range of applications such as structure elucidation; thermodynamic, kinetic, and mechanistic studies; and quantitative analysis. Some of these applications are beyond the scope of compendial methods.

All five characteristics of the signal—chemical shift, multiplicity, line width, coupling constants, and relative intensity—contribute analytical information.

Qualitative Applications— Comparison of a spectrum from the literature or from an authentic specimen with that of a test specimen may be used to confirm the identity of a compound and to detect the presence of impurities that generate extraneous signals. The NMR spectra of simple structures can be adequately described by the numeric value of the chemical shifts and coupling constants, and by the number of protons under each signal. (The software of modern instruments includes programs that generate simulated spectra using these data.) Experimental details, such as the solvent used, the specimen concentration, and the chemical shift reference, must also be provided.

For unknown specimens, NMR analysis, usually coupled with other analytical techniques, is a powerful tool for structure elucidation. Chemical shifts provide information on the chemical environment of the nuclei. Extensive literature is available with correlation charts and rules for predicting chemical shifts. The multiplicity of the signals provides important stereochemical information. Mutual signal splitting of functional groups indicates close proximity. The magnitude of the coupling constant,  $J$ , between residual protons on substituted

aromatic, olefinic, or cycloalkyl structures is used to identify the relative position of the substituents.

Several special techniques (double resonance, chemical exchange, use of shift reagents, two-dimensional analysis, etc.) are available to simplify some of the more complex spectra, to identify certain functional groups, and to determine coupling correlations.

Double resonance, or spin decoupling, is a technique that removes the coupling between nuclei and thus simplifies the spectrum and identifies the components in a coupling relationship. For example, in a simple two-proton system, generally designated an AX system (see Figure 4), each proton appears as a doublet. If a strong radio-frequency field is introduced at the frequency of X, while the normal radio-frequency field is maintained at the frequency that causes A to resonate, the coupling between A and X is removed (homonuclear decoupling). A is no longer split, but instead appears as a singlet. Routine  $^{13}\text{C}$  spectra are obtained under proton decoupling conditions that remove all heteronuclear  $^{13}\text{C}$ - $^1\text{H}$  couplings. As a result of this decoupling, the carbon signals appear as singlets, unless other nuclei that are not decoupled are present (e.g.,  $^{19}\text{F}$ ,  $^{31}\text{P}$ ).

Functional groups containing exchangeable protons bound to hetero-atoms such as  $-\text{OH}$ ,  $-\text{NH}_2$ , or  $-\text{COOH}$  groups may be identified by taking advantage of the rapid exchange of these protons with  $\text{D}_2\text{O}$ . To determine the presence and position of these groups, scan the test substance in  $\text{CDCl}_3$  or  $\text{DMSO-d}_6$ , then add a few drops of  $\text{D}_2\text{O}$  to the specimen tube, shake, and scan again. The resonance peaks from these groups collapse in the second scan and are replaced by the  $\text{HDO}$  singlet between 4.7 and 5.0 ppm.

This chemical exchange is an example of the effect of intermolecular and intramolecular rate processes on NMR spectra. If a proton can experience different environments by virtue of such a process (tautomerism, rotation about a bond, exchange equilibria, ring inversion, etc.), the appearance of the spectrum will be a function of the rate of the process. Slow processes (on an NMR time scale) result in more than one signal, fast processes average these signals to one line, and intermediate processes produce broad signals.

The software of modern FT-NMR spectrometers allows for sequences of pulses much more complex than the repetitive accumulation of transients described above. Such experiments include homonuclear or heteronuclear two-dimensional analysis, which determines the correlation of couplings and may simplify the interpretation of otherwise complex spectra.

**Quantitative Applications**— If appropriate instrument settings for quantitative analysis have been made, the areas (or intensities) of two signals are proportional to the total number of protons generating the signals.

$$\frac{A_1}{A_2} = \frac{N_1}{N_2} \quad (1)$$

If the two signals originate from two functional groups of the same molecule, the equation can be simplified to

$$\frac{A_1}{A_2} = \frac{n_1}{n_2} \quad (2)$$

in which  $n_1$  and  $n_2$  are the number of protons in the respective functional groups.

If the two signals originate from different molecular species,

$$\frac{A_1}{A_2} = \frac{n_1 m_1}{n_2 m_2} = \frac{n_1 W_1 / M_1}{n_2 W_2 / M_2} \quad (3)$$

where  $m_1$  and  $m_2$  are the numbers of moles;  $W_1$  and  $W_2$  are the masses; and  $M_1$  and  $M_2$  are the molecular weights of compounds 1 and 2, respectively.

Examination of Equations 2 and 3 shows that NMR quantitative analysis can be performed in an absolute or relative manner. In the absolute method, an internal standard is added to the specimen and a resonance peak area arising from the test substance is compared with a resonance peak area from the internal standard. If both test substance and internal standard are accurately weighed, the absolute purity of the substance may be calculated. A good internal standard has the following properties: it presents a reference resonance peak, preferably a singlet, at a field position removed from all specimen peaks; it is soluble in the analytical solvent; its proton equivalent weight, i.e., the molecular weight divided by the number of protons giving rise to the reference peak, is low; and it does not interact with the compound being tested. Typical examples of useful standards are 1,2,4,5-tetrachlorobenzene, 1,4-dinitrobenzene, benzyl benzoate, and maleic acid. The choice of a standard will be dictated by the spectrum of the specimen.

The relative method may be used to determine the molar fraction of an impurity in a test substance (or of the components in a mixture) as calculated by Equation 3.

Quantitative analysis, as well as detection of trace impurities, is markedly improved with modern instrumentation. Stronger magnetic fields and the ability to accumulate and/or average signals over long periods of time greatly enhance the sensitivity of the method.

**Absolute Method of Quantitation**— Where the individual monograph directs that the Absolute Method of Quantitation be employed, proceed as follows.  
**Solvent, Internal Standard, and NMR Reference**— Use as directed in the individual monograph.

**Test Preparation**— Transfer an accurately weighed quantity of the test substance, containing about 4.5 proton mEq, to a glass-stoppered, graduated centrifuge tube. Add about 4.5 proton mEq of Internal Standard, accurately weighed, and 3.0 mL of Solvent, insert the stopper, and shake. When dissolution is complete, add about 30  $\mu\text{L}$  (30 mg if a solid) of NMR Reference, provided that it does not interfere with subsequent measurements, and shake.

**Procedure**— Transfer an appropriate amount (0.4 to 0.8 mL) of Test Preparation to a standard 5-mm NMR spinning tube, and record the spectrum, adjusting the spin rate so that no spinning side bands interfere with the peaks of interest. Measure the area under each of the peaks specified in the individual monograph by integrating not fewer than five times.

Record the average area of the Internal Standard peak as AS and that of the Test Preparation peak as AU.

Calculate the quantity, in mg, of the analyte in the Test Preparation by the formula:

$$W_S (A_U / A_S) (E_U / E_S)$$

in which  $W_S$  is the weight, in mg, of Internal Standard taken; and  $E_U$  and  $E_S$  are the proton equivalent weights (i.e., the molecular weights divided by the number of protons giving rise to the reference peak) of the analyte and the Internal Standard, respectively.

**Relative Method of Quantitation**— Where the individual monograph directs that the Relative Method of Quantitation be employed, proceed as follows.  
**Solvent, NMR Reference, and Test Preparation**— Use as directed under Absolute Method of Quantitation.

**Procedure**— Transfer an appropriate amount (0.4 to 0.8 mL) of Test Preparation to a standard 5-mm NMR spinning tube, and record the spectrum, adjusting the spin rate so that no spinning side bands interfere with the peaks of interest. Measure the area or intensity under each of the peaks specified in the individual monograph by integrating not fewer than five times. Record the average area or intensity resulting from the resonances of the groups designated in the individual monograph as  $A_1$  and  $A_2$ .

Calculate the quantity, in mole percent, of the analyte in the Test Preparation by the formula:

$$100 (A_1 / n_1) / [(A_1 / n_1) + (A_2 / n_2)]$$

in which  $n_1$  and  $n_2$  are, respectively, the numbers of protons in the designated groups.

### 771 OPHTHALMIC OINTMENTS

**Added Substances**— Suitable substances may be added to ophthalmic ointments to increase stability or usefulness, unless proscribed in the individual monograph, provided they are harmless in the amounts administered and do not interfere with the therapeutic efficacy or with the responses to the specified assays and tests. No coloring agent may be added, solely for the purpose of coloring the finished preparation, to an article intended for ophthalmic use (see also [Added Substances under General Notices](#) and under [Antimicrobial Effectiveness Testing](#) (51)).

A suitable substance or mixture of substances to prevent the growth of microorganisms must be added to ophthalmic ointments that are packaged in multiple-use containers, regardless of the method of sterilization employed, unless otherwise directed in the individual monograph, or unless the formula itself is bacteriostatic. Such substances are used in concentrations that will prevent the growth of or kill microorganisms in the ophthalmic ointments (see also [Antimicrobial Effectiveness Testing](#) (51)) and [Antimicrobial Agents—Content](#) (341)). Sterilization processes are employed for the finished ointment or for all ingredients, if the ointment is manufactured under rigidly aseptic conditions, even though such substances are used (see also [Parenteral and Topical Preparations](#) in the section [Added Substances](#), under General Notices, and [Sterilization and Sterility Assurance of Compendial Articles](#) (121)). Ophthalmic ointments that are packaged in single-use containers are not required to contain antibacterial agents; however, they meet the requirements for [Sterility Tests](#) (71).

**Containers**— Containers, including the closures, for ophthalmic ointments do not interact physically or chemically with the preparation in any manner to alter the strength, quality, or purity beyond the official requirements under the ordinary or customary conditions of handling, shipment, storage, sale, and use.

**Metal Particles**— Follow the Procedure set forth under [Metal Particles in Ophthalmic Ointments](#) (751).

**Leakage**— Select 10 tubes of the Ointment, with seals applied when specified. Thoroughly clean and dry the exterior surfaces of each tube with an absorbent cloth. Place the tubes in a horizontal position on a sheet of absorbent blotting paper in an oven maintained at a temperature of  $60 \pm 3^\circ$  for 8 hours. No significant leakage occurs during or at the completion of the test (disregard traces of ointment presumed to originate externally from within the crimp of the tube or from the thread of the cap). If leakage is observed from one, but not more than one, of the tubes, repeat the test with 20 additional tubes of the Ointment. The requirement is met if no leakage is observed from the first 10 tubes tested, or if leakage is observed from not more than one of 30 tubes tested.

Auxiliary Information— Please [check for your question in the FAQs](#) before contacting USP.

### 776 OPTICAL MICROSCOPY

Optical microscopy for particle characterization can generally be applied to particles 1  $\mu\text{m}$  and greater. The lower limit is imposed by the resolving power of the microscope. The upper limit is less definite and is determined by the increased difficulty associated with the characterization of larger particles. Various alternative techniques are available for particle characterization outside the applicable range of optical microscopy. Optical microscopy is particularly useful for characterizing particles that are not spherical. This method may also serve as a base for the calibration of faster and more routine methods that may be developed.

**Apparatus**— Use a microscope that is stable and protected from vibration. The microscope magnification (product of the objective magnification, ocular magnification, and additional magnifying components) must be sufficient to allow adequate characterization of the smallest particles to be classified in the test specimen. The greatest numerical aperture of the objective should be sought for each magnification range. Polarizing filters may be used in conjunction with suitable analyzers and retardation plates. Color filters of relatively narrow spectral transmission should be used with achromatic objectives, are preferable with apochromats, and are required for appropriate color rendition in photomicrography. Condensers corrected at least for spherical aberration should be used in the microscope substage and with the lamp. The numerical aperture of the substage condenser should match that of the objective under the conditions of use and is affected by the actual aperture of the condenser diaphragm and by the presence of immersion oils.

**Adjustment**— The precise alignment of all elements of the optical system and proper focusing are essential. The focusing of the elements should be done in accordance with the recommendations of the microscope manufacturer. Critical axial alignment is recommended.

**Illumination**— A requirement for good illumination is a uniform and adjustable intensity of light over the entire field of view; Kohler illumination is preferred. With colored particles, choose the color of the filters used so as to control the contrast and detail of the image.

**Visual Characterization**— The magnification and numerical aperture should be sufficiently high to allow adequate resolution of the images of the particles to be characterized. Determine the actual magnification using a calibrated stage micrometer to calibrate an ocular micrometer. Errors can be minimized if the magnification is sufficient that the image of the particle is at least 10 ocular divisions. Each objective must be calibrated separately. To calibrate the ocular scale, the stage micrometer scale and the ocular scale should be aligned. In this way, a precise determination of the distance between ocular stage divisions can be made. Several different magnifications may be necessary to characterize materials having a wide particle size distribution.

**Photographic Characterization**— If particle size is to be determined by photographic methods, take care to ensure that the object is sharply focused at the plane of the photographic emulsion. Determine the actual magnification by photographing a calibrated stage micrometer, using photographic film of sufficient speed, resolving power, and contrast. Exposure and processing should be identical for photographs of both the test specimen and the determination of magnification. The apparent size of a photographic image is influenced by the exposure, development, and printing processes as well as by the resolving power of the microscope.

**Preparation of the Mount**— The mounting medium will vary according to the physical properties of the test specimen. Sufficient but not excessive contrast between the specimen and the mounting medium is required to ensure adequate detail of the specimen edge. The particles should rest in one plane and be adequately dispersed to distinguish individual particles of interest. Furthermore, the particles must be representative of the distribution of sizes in the material and must not be altered during preparation of the mount. Care should be taken to ensure that this important requirement is met. Selection of the mounting medium must include a consideration of the analyte solubility.

**Crystallinity Characterization**— The crystallinity of a material may be characterized to determine compliance with the crystallinity requirement where stated in the individual monograph of a drug substance. Unless otherwise specified in the individual monograph, mount a few particles of the specimen in mineral oil on a clean glass slide. Examine the mixture using a polarizing microscope: the particles show birefringence (interference colors) and extinction positions when the microscope stage is revolved.

**Limit Test of Particle Size by Microscopy**— Weigh a suitable quantity of the powder to be examined (for example, 10 to 100 mg), and suspend it in 10 mL of a suitable medium in which the powder does not dissolve, adding, if necessary, a wetting agent. A homogeneous suspension of particles can be maintained by suspending the particles in a medium of similar or matching density and by providing adequate agitation. Introduce a portion of the homogeneous suspension into a suitable counting cell, and scan under a microscope an area corresponding to not less than 10  $\mu\text{g}$  of the powder to be examined. Count all the particles having a maximum dimension greater than the prescribed size limit. The size limit and the permitted number of particles exceeding the limit are defined for each substance.

**Particle Size Characterization**— The measurement of particle size varies in complexity depending on the shape of the particle, and the number of particles characterized must be sufficient to ensure an acceptable level of uncertainty in the measured parameters. Additional information on particle size measurement, sample size, and data analysis is available, for example, in ISO 9276. For spherical particles, size is defined by the diameter. For irregular particles, a variety of definitions of particle size exist. In general, for irregularly shaped particles, characterization of particle size must also include information on the type of diameter measured as well as information on particle shape. Several commonly used measurements of particle size are defined below (see [Figure 1](#)):

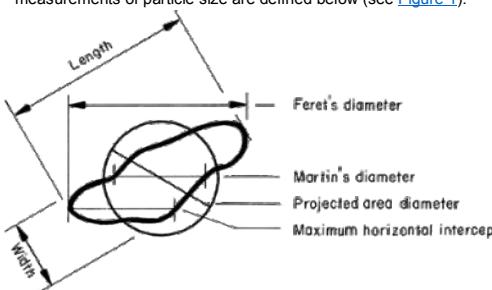

Fig. 1. Commonly used measurements of particle size.

**Feret's Diameter**— The distance between imaginary parallel lines tangent to a randomly oriented particle and perpendicular to the ocular scale.

**Martin's Diameter**— The diameter of the particle at the point that divides a randomly oriented particle into two equal projected areas.

**Projected Area Diameter**— The diameter of a circle that has the same projected area as the particle.

**Length**— The longest dimension from edge to edge of a particle oriented parallel to the ocular scale.

**Width**— The longest dimension of the particle measured at right angles to the length.

**Particle Shape Characterization**— For irregularly shaped particles, characterization of particle size must also include information on particle shape. The homogeneity of the powder should be checked using appropriate magnification. The following defines some commonly used descriptors of particle shape (see [Figure 2](#)):

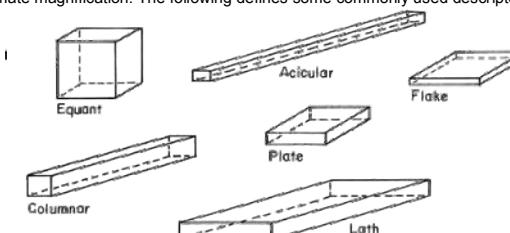

Fig. 2. Commonly used descriptions of particle shape.

**Acicular**— Slender, needle-like particle of similar width and thickness.

**Columnar**— Long, thin particle with a width and thickness that are greater than those of an acicular particle.

**Flake**— Thin, flat particle of similar length and width.

**Plate**— Flat particles of similar length and width but with greater thickness than flakes.

**Lath**— Long, thin, and blade-like particle.

**Equant**— Particles of similar length, width, and thickness; both cubical and spherical particles are included.

**General Observations**— A particle is generally considered to be the smallest discrete unit. A particle may be a liquid or semisolid droplet; a single crystal or polycrystalline; amorphous or an agglomerate. Particles may be associated. This degree of association may be described by the following terms:

**Lamellar**— Stacked plates.

**Aggregate**— Mass of adhered particles.

**Agglomerate**— Fused or cemented particles.

**Conglomerate**— Mixture of two or more types of particles.

**Spherulite**— Radial cluster.

**Drusy**— Particle covered with tiny particles.

Particle condition may be described by the following terms:

**Edges**— Angular, rounded, smooth, sharp, fractured.

**Optical**— Color (using proper color-balancing filters), transparent, translucent, opaque.

**Defects**— Occlusions, inclusions.

Surface characteristics may be described as:

Cracked— Partial split, break, or fissure.

Smooth— Free of irregularities, roughness, or projections.

Porous— Having openings or passageways.

Rough— Bumpy, uneven, not smooth.

Pitted— Small indentations.

### 781 OPTICAL ROTATION

Many pharmaceutical substances are optically active in the sense that they rotate an incident plane of polarized light so that the transmitted light emerges at a measurable angle to the plane of the incident light. This property is characteristic of some crystals and of many pharmaceutical liquids or solutions of solids. Where the property is possessed by a liquid or by a solute in solution, it is generally the result of the presence of one or more asymmetric centers, usually a carbon atom with four different substituents. The number of optical isomers is  $2^n$ , where n is the number of asymmetric centers. Polarimetry, the measurement of optical rotation, of a pharmaceutical article may be the only convenient means for distinguishing optically active isomers from each other and thus is an important criterion of identity and purity.

Substances that may show optical rotatory power are chiral. Those that rotate light in a clockwise direction as viewed towards the light source are dextrorotatory, or (+) optical isomers. Those that rotate light in the opposite direction are called levorotatory or (-) optical isomers. (The symbols d- and l-, formerly used to indicate dextro- and levorotatory isomers, are no longer sanctioned owing to confusion with d- and l-, which refer to configuration relative to d-glyceraldehyde. The symbols R and S and  $\alpha$  and  $\beta$  are also used to indicate configuration, the arrangement of atoms or groups of atoms in space.)

The physicochemical properties of nonsuperimposable chiral substances rotating plane polarized light in opposite directions to the same extent, enantiomers, are identical, except for this property and in their reactions with other chiral substances. Enantiomers often exhibit profound differences in pharmacology and toxicology, owing to the fact that biological receptors and enzymes themselves are chiral. Many articles from natural sources, such as amino acids, proteins, alkaloids, antibiotics, glycosides, and sugars, exist as chiral compounds. Synthesis of such compounds from nonchiral materials results in equal numbers of the enantiomers, racemates. Racemates have a net null optical rotation, and their physical properties may differ from those of the component enantiomers. Use of stereoselective or stereospecific synthetic methods or separation of racemic mixtures can be used to obtain individual optical isomers.

Measurement of optical rotation is performed using a polarimeter.<sup>1</sup> The general equation used in polarimetry is:

$$[\alpha]_{\lambda}^t = \frac{100a}{lc}$$

where  $[\alpha]$  is the specific rotation at wavelength  $\lambda$ , t is the temperature, a is the observed rotation in degrees ( $^{\circ}$ ), l is the pathlength in decimeters, and c is the concentration of the analyte in g per 100 mL. Thus,  $[\alpha]$  is 100 times the measured value, in degrees ( $^{\circ}$ ), for a solution containing 1 g in 100 mL, measured in a cell having a pathlength of 1.0 decimeter under defined conditions of incident wavelength of light and temperature. For some Pharmacopeial articles, especially liquids such as essential oils, the optical rotation requirement is expressed in terms of the observed rotation, a, measured under conditions defined in the monograph.

Historically, polarimetry was performed using an instrument where the extent of optical rotation is estimated by visual matching of the intensity of split fields. For this reason, the d-line of the sodium lamp at the visible wavelength of 589 nm was most often employed. Specific rotation determined at the d-line is expressed by the symbol:

$$[\alpha]_D^{25} \text{ or } [\alpha]_D^{20}$$

and much of the data available are expressed in this form. Use of lower wavelengths, such as those available with the mercury lamp lines isolated by means of filters of maximum transmittance at approximately 578, 546, 436, 405, and 365 nm in a photoelectric polarimeter, has been found to provide advantages in sensitivity with a consequent reduction in the concentration of the test compound. In general, the observed optical rotation at 436 nm is about double and at 365 nm about three times that at 589 nm. Reduction in the concentration of the solute required for measurement may sometimes be accomplished by conversion of the substance under test to one that has a significantly higher optical rotation. Optical rotation is also affected by the solvent used for the measurement, and this is always specified.

It is now common practice to use other light sources, such as xenon or tungsten halogen, with appropriate filters, because these may offer advantages of cost, long life, and broad wavelength emission range, over traditional light sources.

Specific Rotation— The reference [Specific rotation](#) in a monograph signifies that specific rotation is to be calculated from observed optical rotations in the Test solution obtained as directed therein. Unless otherwise directed, measurements of optical rotation are made at 589 nm at  $25^{\circ}$ . Where a photoelectric polarimeter is used, a single measurement, corrected for the solvent blank, is made. Where a visual polarimeter is employed, the average of no fewer than five determinations, corrected for the reading of the same tube with a solvent blank, is used. Temperature, which applies to the solution or the liquid under test, should be maintained within  $0.5^{\circ}$  of the stated value. Use the same cell for sample and blank. Maintain the same angular orientation of the cell in each reading. Place the cell so that the light passes through it in the same direction each time. Unless otherwise specified, specific rotation is calculated on the dried basis where Loss on drying is specified in the monograph or on the anhydrous basis where Water is specified.

Optical rotation of solutions should be determined within 30 minutes of preparation. In the case of substances known to undergo racemization or mutarotation, care should be taken to standardize the time between adding the solute to the Solvent and introduction of the solution into the polarimeter tube.

Angular Rotation— The reference [Angular rotation](#) in a monograph signifies, unless otherwise directed, that the optical rotation of the neat liquid is measured in a 1.0-dm tube at 589 nm at  $25^{\circ}$ , corrected for the reading of the dry empty tube.

\* Suitable calibrators are available from the Office of Standard Reference Materials, National Institute of Standards and Technology (NIST), Gaithersburg, MD 20899, as current lots of

Standard Reference Materials, Dextrose and Sucrose. Alternatively, calibration may be checked using a Polarization Reference Standard, which consists of a plate of quartz mounted in a holder perpendicular to the light path. These standards are available, traceable to NIST, from Rudolph Research Analytical, 354 Route 206, Flanders, NJ 07836, or from Rudolph Instruments, Inc., 40 Pier Lane, Fairfield, NJ 07004-2113.

## 785 OSMOLALITY AND OSMOLARITY

### INTRODUCTION

Osmotic pressure plays a critical role in all biological processes that involve diffusion of solutes or transfer of fluids through membranes. Osmosis occurs when solvent but not solute molecules cross a semipermeable membrane from regions of lower to higher concentrations to produce equilibrium. The knowledge of osmotic pressures is important for practitioners in determining whether a parenteral solution is hypo-osmotic, iso-osmotic, or hyperosmotic. A quantitative measure of osmotic pressure facilitates the dilution required to render a solution iso-osmotic relative to whole blood.

### OSMOTIC PRESSURE

The osmotic pressure of a solution depends on the number of particles in solution, and is therefore referred to as a colligative property. A particle can be a molecule or an ion or an aggregated species (e.g., a dimer) that can exist discretely in solution. A solution exhibits ideal behavior when no interaction occurs between solutes and solvent, except where solvent molecules are bound to solutes by hydrogen bonding or coordinate covalency. For such a solution containing a nondissociating solute, the osmotic pressure ( $\pi$ ) is directly proportional to its molality (number of moles of solute per kilogram of the solvent):

$$\pi = (P RT/1000)m,$$

where  $P$  is the density of the solvent at the temperature  $T$  (in the absolute scale);  $R$  is the universal gas constant; and  $m$  is the molality of the solution. For a real solution containing more than one solute, the osmotic pressure is given by the formula:

$$\pi = (P RT/1000)\sum \pi_i m_i \phi_{m,i}$$

where  $\pi_i$  is the number of particles formed by the dissociation of one molecule of the  $i$ th solute;  $\pi_i = 1$  for nonionic (nondissociating) solutes;  $m_i$  is the molality of the  $i$ th solute; and  $\phi_{m,i}$  is the molal osmotic coefficient of the  $i$ th solute. The molal osmotic coefficient takes into account the deviation of a solution from ideal behavior. Its value depends upon the concentration of the solute(s) in solution, its chemical properties, and ionic characteristics. The value of the molal osmotic coefficient of a solute can be determined experimentally by measuring the freezing point depression at different molal concentrations. At concentrations of pharmaceutical interest, the value of the molal osmotic coefficient is less than one. The molal osmotic coefficient decreases with the increase in concentration of the solute ([Table 1](#)).

### OSMOLALITY

The osmolality of a solution  $\bar{\pi}_m$  is given by

$$\bar{\pi}_m = \sum \pi_i m_i \phi_{m,i}$$

The osmolality of a real solution corresponds to the molality of an ideal solution containing nondissociating solutes and is expressed in osmoles or milliosmoles per kilogram of solvent (Osmol per kg or mOsmol per kg, respectively), a unit that is similar to the molality of the solution. Thus, osmolality is a measure of the osmotic pressure exerted by a real solution across a semipermeable membrane. Like osmotic pressure, other colligative properties of a solution, such as vapor pressure lowering, boiling point elevation, and freezing point depression, are also directly related to the osmolality of the solution. Indeed, the osmolality of a solution is typically determined most accurately and conveniently by measuring freezing point depression ( $\Delta T_f$ ):

$$\Delta T_f = k_f \bar{\pi}_m$$

where  $k_f$  is the molal cryoscopic constant, which is a property of the solvent. For water, the value of  $k_f$  is  $1.860^{\circ}$  per Osmol. That is, 1 Osmol of a solute added to 1 kg of water lowers the freezing point by  $1.860^{\circ}$ .

### OSMOLARITY

Osmolarity of a solution is a theoretical quantity expressed in osmoles per L (Osmol per L) of a solution and is widely used in clinical practice because it expresses osmoles as a function of volume. Osmolarity cannot be measured but is calculated theoretically from the experimentally measured value of osmolality.

Sometimes, osmolarity ( $\bar{\pi}_c$ ) is calculated theoretically from the molar concentrations:

$$\bar{\pi}_c = \sum \pi_i c_i$$

where  $\pi_i$  is as defined above, and  $c_i$  is the molar concentration of the  $i$ th solute in solution. For example, the osmolarity of a solution prepared by dissolving 1 g of vancomycin in 100 mL of 0.9% sodium chloride solution can be calculated as follows:

$$[3 \times 10 \text{ g/L}/1449.25(\text{mol. wt. of vancomycin}) + 2 \times 9 \text{ g/L}/58.44(\text{mol. wt. of sodium chloride})] \times 1000 = 329 \text{ mOsmol/L}$$

The results suggest that the solution is slightly hyperosmotic because the osmolality of blood ranges between 285 and 310 mOsmol per kg. However, the solution is found to be hypo-osmotic and has an experimentally determined osmolality of 255 mOsmol per kg.<sup>1</sup> The example illustrates that osmolarity values calculated theoretically from the concentration of a solution should be interpreted cautiously and may not represent the osmotic properties of infusion solutions.

The discrepancy between theoretical (osmolarity) and experimental (osmolality) results is, in part, due to the fact that osmotic pressure is related to osmolality and not osmolarity. More significantly, the discrepancy between experimental results and the theoretical calculation is due to the fact that the osmotic pressure of a real solution is less than that of an ideal solution because of interactions between solute molecules or between solute and solvent molecules in a solution. Such interactions reduce the pressure exerted by solute molecules on a semipermeable membrane, reducing experimental values of osmolality compared to theoretical values. This difference is related to the molal osmotic coefficient ( $\phi_{m,i}$ ). The example also illustrates the importance of determining the osmolality of a solution experimentally, rather than calculating the value theoretically.

### MEASUREMENT OF OSMOLALITY

The osmolality of a solution is commonly determined by the measurement of the freezing point depression of the solution.

Apparatus— The apparatus, an osmometer for freezing point depression measurement, consists of the following: a means of cooling the container used for the measurement; a resistor sensitive to temperature (thermistor), with an appropriate current- or potential-difference measurement device that may be graduated in temperature change or in osmolality; and a means of mixing the sample.

Osmometers that measure the vapor pressures of solutions are less frequently employed. They require a smaller volume of specimen (generally about 5  $\mu$ L), but the accuracy and precision of the resulting osmolality determination are comparable to those obtained by the use of osmometers that depend upon the observed freezing points of solutions.

Standard Solutions— Prepare Standard Solutions as specified in [Table 1](#), as necessary.

Table 1. Standard Solutions for Osmometer Calibration<sup>2</sup>

Standard Solutions (Weight in g of sodium chloride per kg of water)	Osmolality (mOsmol/kg) ( $\bar{m}$ )	Molal Osmotic Coefficient ( $\phi_m$ , NaCl)	Freezing Point Depression ( $^\circ$ ) $\Delta T_f$
3.087	100	0.9463	0.186
6.260	200	0.9337	0.372
9.463	300	0.9264	0.558
12.684	400	0.9215	0.744
15.916	500	0.9180	0.930
19.147	600	0.9157	1.116
22.380	700	0.9140	1.302

2. Adapted from the European Pharmacopoeia, 4th Edition, 2002, p. 50.

Test Solution— For a solid for injection, constitute with the appropriate diluent as specified in the instructions on the labeling. For solutions, use the sample as is. [note—A solution can be diluted to bring it within the range of measurement of the osmometer, if necessary, but the results must be expressed as that of the diluted solution and must NOT be multiplied by a dilution factor to calculate the osmolality of the original solution, unless otherwise indicated in the monograph. The molal osmotic coefficient is a function of concentration. Therefore, it changes with dilution.]

Procedure— First, calibrate the instrument by the manufacturer's instructions. Confirm the instrument calibration with at least two solutions from Table 1 such that the osmolalities of the Standard Solutions span the expected range of osmolality of the Test Solution. The instrument reading should be within  $\pm 2$  mOsmol/kg from the Standard Solution (over the standard range of 100 to 700 mOsmol/kg). Introduce an appropriate volume of each Standard Solution into the measurement cell as per the manufacturer's instructions, and start the cooling system. Usually, the mixing device is programmed to operate at a temperature below the lowest temperature expected from the freezing point depression. The apparatus indicates when the equilibrium is attained. Calibrate the osmometer using an appropriate adjustment device such that the reading corresponds to either the osmolality or freezing point depression value of the Standard Solution shown in Table 1. [note—Some instruments indicate osmolality and some others show freezing point depression.] Before each measurement, rinse the measurement cell at least twice with the solution to be tested. Repeat the procedure with each Test Solution. Read the osmolality of the Test Solution directly, or calculate it from the measured freezing point depression.

Assuming that the value of the osmotic coefficient is essentially the same whether the concentration is expressed in molality or molarity, the experimentally determined osmolality of a solution can be converted to osmolarity in the same manner in which the concentration of a solution is converted from molality to molarity. Unless a solution is very concentrated, the osmolarity of a solution ( $\bar{c}$ ) can be calculated from its experimentally determined osmolality ( $\bar{m}$ ):

$$\bar{c} = 1000 \bar{m} / (1000 / \rho + \sum w_i V_i)$$

where  $w_i$  is the weight in g; and  $V_i$  is the partial specific volume, in mL per g, of the  $i$ th solute. The partial specific volume of a solute is the change in volume of a solution when an additional 1 g of solute is dissolved in the solution. This volume can be determined by the measurement of densities of the solution before and after the addition of the solute. The partial specific volumes of salts are generally very small, around 0.1 mL per g. However, those of other solutes are generally higher. For example, the partial specific volumes of amino acids are in the range of 0.6–0.9 mL per g. It can be shown from the above equation correlating osmolarity with osmolality that,

$$\bar{c} = \bar{m} (\rho - c)$$

where  $\rho$  is the density of the solution, and  $c$  is the total solute concentration, both expressed in g per mL. Thus, alternatively, the osmolarity can also be calculated from experimentally determined osmolality from the measurement of density of the solution by a suitable method and the total weight of the solute, after correction for water content, dissolved per mL of the solution.

#### 786 PARTICLE SIZE DISTRIBUTION ESTIMATION BY ANALYTICAL SIEVING

Sieving is one of the oldest methods of classifying powders and granules by particle size distribution. When using a woven sieve cloth, the sieving will essentially sort the particles by their intermediate size dimension (i.e., breadth or width). Mechanical sieving is most suitable where the majority of the particles are larger than about 75  $\mu$ m. For smaller particles, the light weight provides insufficient force during sieving to overcome the surface forces of cohesion and adhesion that cause the particles to stick to each other and to the sieve, and thus cause particles that would be expected to pass through the sieve to be retained. For such materials, other means of agitation such as air-jet sieving or sonic sifting may be more appropriate. Nevertheless, sieving can sometimes be used for some powders or granules having median particle sizes smaller than 75  $\mu$ m where the method can be validated. In pharmaceutical terms, sieving is usually the method of choice for classification of the coarser grades of single powders or granules. It is a particularly attractive method in that powders and granules are classified only on the basis of particle size, and in most cases the analysis can be carried out in the dry state.

Among the limitations of the sieving method are the need for an appreciable amount of sample (normally at least 25 g, depending on the density of the powder or granule, and the diameter of test sieves) and difficulty in sieving oily or other cohesive powders or granules that tend to clog the sieve openings. The method is essentially a two-dimensional estimate of size because passage through the sieve aperture is frequently more dependent on maximum width and thickness than on length.

This method is intended for estimation of the total particle size distribution of a single material. It is not intended for determination of the proportion of particles passing or retained on one or two sieves.

Estimate the particle size distribution as described under Dry Sieving Method, unless otherwise specified in the individual monograph. Where difficulty is experienced in reaching the endpoint (i.e., material does not readily pass through the sieves) or when it is necessary to use the finer end of the sieving range (below 75  $\mu$ m), serious consideration should be given

to the use of an alternative particle-sizing method.

Sieving should be carried out under conditions that do not cause the test sample to gain or lose moisture. The relative humidity of the environment in which the sieving is carried out should be controlled to prevent moisture uptake or loss by the sample. In the absence of evidence to the contrary, analytical test sieving is normally carried out at ambient humidity.

Any special conditions that apply to a particular material should be detailed in the individual monograph.

**Principles of Analytical Sieving**— Analytical test sieves are constructed from a woven-wire mesh, which is of simple weave that is assumed to give nearly square apertures and is sealed into the base of an open cylindrical container. The basic analytical method involves stacking the sieves on top of one another in ascending degrees of coarseness, and then placing the test powder on the top sieve.

The nest of sieves is subjected to a standardized period of agitation, and then the weight of material retained on each sieve is accurately determined. The test gives the weight percentage of powder in each sieve size range.

This sieving process for estimating the particle size distribution of a single pharmaceutical powder is generally intended for use where at least 80% of the particles are larger than 75  $\mu\text{m}$ . The size parameter involved in determining particle size distribution by analytical sieving is the length of the side of the minimum square aperture through which the particle will pass.

#### TEST SIEVES

Test sieves suitable for pharmacopeial tests conform to the most current edition of International Organization for Standardization Specification ISO 3310-1: Test Sieves—Technical Requirements and Testing (see [Table 1](#)). Unless otherwise specified in the monograph, use those ISO sieves listed as principal sizes in [Table 1](#). Unless otherwise specified in the monograph, use those ISO sieves listed in [Table 1](#) as recommended in the particular region.

	40 $\mu\text{m}$					
		38 $\mu\text{m}$			38	391

Sieves are selected to cover the entire range of particle sizes present in the test specimen. A nest of sieves having a  $\sqrt{2}$  progression of the area of the sieve openings is recommended. The nest of sieves is assembled with the coarsest screen at the top and the finest at the bottom. Use micrometers or millimeters in denoting test sieve openings. [note—Mesh numbers are provided in the table for conversion purposes only.] Test sieves are made from stainless steel or, less preferably, from brass or other suitable nonreactive wire.

Calibration and recalibration of test sieves is in accordance with the most current edition of ISO 3310-1. Sieves should be carefully examined for gross distortions and fractures, especially at their screen frame joints, before use. Sieves may be calibrated optically to estimate the average opening size, and opening variability, of the sieve mesh. Alternatively, for the evaluation of the effective opening of test sieves in the size range of 212 to 850  $\mu\text{m}$ , Standard Glass Spheres are available. Unless otherwise specified in the individual monograph, perform the sieve analysis at controlled room temperature and at ambient relative humidity.

**Cleaning Test Sieves**— Ideally, test sieves should be cleaned using only an air jet or a liquid stream. If some apertures remain blocked by test particles, careful gentle brushing may be used as a last resort.

**Test Specimen**— If the test specimen weight is not given in the monograph for a particular material, use a test specimen having a weight between 25 and 100 g, depending on the bulk density of the material, and test sieves having a 200-mm diameter. For 76-mm sieves, the amount of material that can be accommodated is approximately 1/7th that which can be accommodated on a 200-mm sieve. Determine the most appropriate weight for a given material by test sieving accurately weighed specimens of different weights, such as 25, 50, and 100 g, for the same time period on a mechanical shaker. [note—If the test results are similar for the 25-g and 50-g specimens, but the 100-g specimen shows a lower percentage through the finest sieve, the 100-g specimen size is too large.] Where only a specimen of 10 to 25 g is available, smaller diameter test sieves conforming to the same mesh specifications may be substituted, but the endpoint must be redetermined. The use of test samples having a smaller mass (e.g., down to 5 g) may be needed. For materials with low apparent particle density, or for materials mainly comprising particles with a highly isodiametrical shape, specimen weights below 5 g for a 200-mm screen may be necessary to avoid excessive blocking of the sieve. During validation of a particular sieve analysis method, it is expected that the problem of sieve blocking will have been addressed.

If the test material is prone to picking up or losing significant amounts of water with varying humidity, the test must be carried out in an appropriately controlled environment. Similarly, if the test material is known to develop an electrostatic charge, careful observation must be made to ensure that such charging is not influencing the analysis. An antistatic agent, such as colloidal silicon dioxide and/or aluminum oxide, may be added at a 0.5 percent (m/m) level to minimize this effect. If both of the above effects cannot be eliminated, an alternative particle-sizing technique must be selected.

**Agitation Methods**— Several different sieve and powder agitation devices are commercially available, all of which may be used to perform sieve analyses. However, the different methods of agitation may give different results for sieve analyses and endpoint determinations because of the different types and magnitude of the forces acting on the individual particles under test. Methods using mechanical agitation or electromagnetic agitation, and that can induce either a vertical oscillation or a horizontal circular motion, or tapping or a combination of both tapping and horizontal circular motion are available. Entrainment of the particles in an air stream may also be used. The results must indicate which agitation method was used and the agitation parameters used (if they can be varied), because changes in the agitation conditions will give different results for the sieve analysis and endpoint determinations, and may be sufficiently different to give a failing result under some circumstances.

**Endpoint Determination**— The test sieving analysis is complete when the weight on any of the test sieves does not change by more than 5% or 0.1 g (10% in the case of 76-mm sieves) of the previous weight on that sieve. If less than 5% of the total specimen weight is present on a given sieve, the endpoint for that sieve is increased to a weight change of not more than 20% of the previous weight on that sieve.

If more than 50% of the total specimen weight is found on any one sieve, unless this is indicated in the monograph, the test should be repeated, but with the addition to the sieve nest of a more coarse sieve, intermediate between that carrying the excessive weight and the next coarsest sieve in the original nest, i.e., addition of the ISO series sieve omitted from the nest of sieves.

#### SIEVING METHODS

##### Mechanical Agitation

**Dry Sieving Method**— Tare each test sieve to the nearest 0.1 g. Place an accurately weighed quantity of test specimen on the top (coarsest) sieve, and replace the lid. Agitate the nest of sieves for 5 minutes. Then carefully remove each from the nest without loss of material. Reweigh each sieve, and determine the weight of material on each sieve. Determine the weight of material in the collecting pan in a similar manner. Reassemble the nest of sieves, and agitate for 5 minutes. Remove and weigh each sieve as previously described. Repeat these steps until the endpoint criteria are met (see Endpoint Determination under Test Sieves). Upon completion of the analysis, reconcile the weights of material. Total losses must not exceed 5% of the weight of the original test specimen.

Repeat the analysis with a fresh specimen, but using a single sieving time equal to that of the combined times used above. Confirm that this sieving time conforms to the requirements

endpoint determination. When this endpoint has been validated for a specific material, then a single fixed time of sieving may be used for future analyses, providing the particle size distribution falls within normal variation.

If there is evidence that the particles retained on any sieve are aggregates rather than single particles, the use of mechanical dry sieving is unlikely to give good reproducibility, and a different particle size analysis method should be used.

#### Air Entrainment Methods

Air Jet and Sonic Sifter Sieving— Different types of commercial equipment that use a moving air current are available for sieving. A system that uses a single sieve at a time is referred to as air jet sieving. It uses the same general sieving methodology as that described under the Dry Sieving Method, but with a standardized air jet replacing the normal agitation mechanism. It requires sequential analyses on individual sieves starting with the finest sieve to obtain a particle size distribution. Air jet sieving often includes the use of finer test sieves than those used in ordinary dry sieving. This technique is more suitable where only oversize or undersize fractions are needed.

In the sonic sifting method, a nest of sieves is used, and the test specimen is carried in a vertically oscillating column of air that lifts the specimen and then carries it back against the mesh openings at a given number of pulses per minute. It may be necessary to lower the sample amount to 5 g, when sonic sifting is employed.

The air jet sieving and sonic sieving methods may be useful for powders or granules when mechanical sieving techniques are incapable of giving a meaningful analysis.

These methods are highly dependent upon proper dispersion of the powder in the air current. This requirement may be hard to achieve if the method is used at the lower end of the sieving range (i.e., below 75  $\mu$ m), when the particles tend to be more cohesive, and especially if there is any tendency for the material to develop an electrostatic charge. For the above reasons endpoint determination is particularly critical, and it is very important to confirm that the oversize material comprises single particles and is not composed of aggregates.

#### INTERPRETATION

The raw data must include the weight of test specimen, the total sieving time, and the precise sieving methodology and the set values for any variable parameters, in addition to the weights retained on the individual sieves and in the pan. It may be convenient to convert the raw data into a cumulative weight distribution, and if it is desired to express the distribution in terms of a cumulative weight undersize, the range of sieves used should include a sieve through which all the material passes. If there is evidence on any of the test sieves that the material remaining on it is composed of aggregates formed during the sieving process, the analysis is invalid.

#### 788 PARTICULATE MATTER IN INJECTIONS

This general chapter is harmonized with the corresponding texts of the European Pharmacopoeia and/or the Japanese Pharmacopoeia. These pharmacopeias have undertaken not to make any unilateral change to this harmonized chapter. Portions of the present general chapter text that are national USP text, and therefore not part of the harmonized text, are marked with symbols (♦♦) to specify this fact.

Particulate matter in injections and parenteral infusions consists of mobile undissolved particles, other than gas bubbles, unintentionally present in the solutions.

For the determination of particulate matter, two procedures, Method 1 (Light Obscuration Particle Count Test) and Method 2 (Microscopic Particle Count Test), are specified hereinafter. When examining injections and parenteral infusions for subvisible particles, Method 1 is preferably applied. However, it may be necessary to test some preparations by the Light Obscuration Particle Count Test followed by the Microscopic Particle Count Test to reach a conclusion on conformance to the requirements.

Not all parenteral preparations can be examined for subvisible particles by one or both of these methods. When Method 1 is not applicable, e.g., in the case of preparations having reduced clarity or increased viscosity, the test should be carried out according to Method 2. Emulsions, colloids, and liposomal preparations are examples. Similarly, products that produce air or gas bubbles when drawn into the sensor may also require microscopic particle count testing. If the viscosity of the preparation to be tested is sufficiently high so as to preclude its examination by either test method, a quantitative dilution with an appropriate diluent may be made to decrease viscosity, as necessary, to allow the analysis to be performed.

The results obtained in examining a discrete unit or group of units for particulate matter cannot be extrapolated with certainty to other units that remain untested. Thus, statistically sound sampling plans must be developed if valid inferences are to be drawn from observed data to characterize the level of particulate matter in a large group of units.

#### METHOD 1 LIGHT OBSCURATION PARTICLE COUNT TEST

Use a suitable apparatus based on the principle of light blockage that allows for an automatic determination of the size of particles and the number of particles according to size. The definition for particle-free water is provided in Reagent Specifications under Reagents, Indicators and Solutions.

The apparatus is calibrated using dispersions of spherical particles of known sizes between 10  $\mu$ m and 25  $\mu$ m. These standard particles are dispersed in particle-free water. Care must be taken to avoid aggregation of particles during dispersion. ♦System suitability can be verified by using the [USP Particle Count RS](#).♦

##### General Precautions

The test is carried out under conditions limiting particulate matter, preferably in a laminar flow cabinet.

Very carefully wash the glassware and filtration equipment used, except for the membrane filters, with a warm detergent solution, and rinse with abundant amounts of water to remove all traces of detergent. Immediately before use, rinse the equipment from top to bottom, outside and then inside, with particle-free water.

Take care not to introduce air bubbles into the preparation to be examined, especially when fractions of the preparation are being transferred to the container in which the determination is to be carried out.

In order to check that the environment is suitable for the test, that the glassware is properly cleaned, and that the water to be used is particle-free, the following test is carried out: determine the particulate matter in 5 samples of particle-free water, each of 5 mL, according to the method described below. If the number of particles of 10  $\mu$ m or greater size exceeds 25 for the combined 25 mL, the precautions taken for the test are not sufficient. The preparatory steps must be repeated until the environment, glassware, and water are suitable for the test.

##### Method

Mix the contents of the sample by slowly inverting the container 20 times successively. If necessary, cautiously remove the sealing closure. Clean the outer surfaces of the container opening using a jet of particle-free water and remove the closure, avoiding any contamination of the contents. Eliminate gas bubbles by appropriate measures such as allowing to stand for 2 minutes or sonicating.

For large-volume parenterals, single units are tested. For small-volume parenterals less than 25 mL in volume, the contents of 10 or more units are combined in a cleaned container to obtain a volume of not less than 25 mL; the test solution may be prepared by mixing the contents of a suitable number of vials and diluting to 25 mL with particle-free water or with an

appropriate particle-free solvent when particle-free water is not suitable. Small-volume parenterals having a volume of 25 mL or more may be tested individually.

Powders for parenteral use are reconstituted with particle-free water or with an appropriate particle-free solvent when particle-free water is not suitable.

The number of test specimens must be adequate to provide a statistically sound assessment. For large-volume parenterals or for small-volume parenterals having a volume of 25 mL or more, fewer than 10 units may be tested, using an appropriate sampling plan.

Remove four portions, not less than 5 mL each, and count the number of particles equal to or greater than 10  $\mu\text{m}$  and 25  $\mu\text{m}$ . Disregard the result obtained for the first portion, and calculate the mean number of particles for the preparation to be examined.

#### Evaluation

For preparations supplied in containers with a nominal volume of more than 100 mL, apply the criteria of Test 1.A.

For preparations supplied in containers with a nominal volume of less than 100 mL, apply the criteria of Test 1.B.

For preparations supplied in containers with a nominal volume of 100 mL, apply the criteria of Test 1.B. [note—Test 1.A is used in the Japanese Pharmacopeia.]

If the average number of particles exceeds the limits, test the preparation by the Microscopic Particle Count Test.

Test 1.A (Solutions for parenteral infusion or solutions for injection supplied in containers with a nominal content of more than 100 mL)—The preparation complies with the test if the average number of particles present in the units tested does not exceed 25 per mL equal to or greater than 10  $\mu\text{m}$  and does not exceed 3 per mL equal to or greater than 25  $\mu\text{m}$ .

Test 1.B (Solutions for parenteral infusion or solutions for injection supplied in containers with a nominal content of less than 100 mL)—The preparation complies with the test if the average number of particles present in the units tested does not exceed 6000 per container equal to or greater than 10  $\mu\text{m}$  and does not exceed 600 per container equal to or greater than 25  $\mu\text{m}$ .

### METHOD 2 MICROSCOPIC PARTICLE COUNT TEST

Use a suitable binocular microscope, a filter assembly for retaining particulate matter, and a membrane filter for examination.

The microscope is adjusted to  $100 \pm 10$  magnifications and is equipped with an ocular micrometer calibrated with an objective micrometer, a mechanical stage capable of holding and traversing the entire filtration area of the membrane filter, and two suitable illuminators to provide episcopic illumination in addition to oblique illumination.

The ocular micrometer is a circular diameter graticule (see [Figure 1](#))

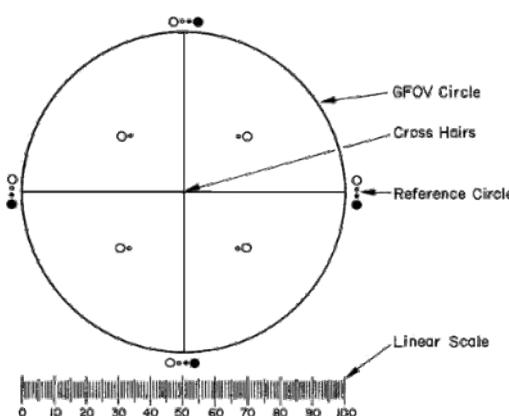

Fig. 1. Circular diameter graticule. The large circle divided by crosshairs into quadrants is designated the graticule field of view (GFOV). Transparent and black circles having 10- $\mu\text{m}$  and 25- $\mu\text{m}$  diameters at 100 $\times$  are provided as comparison scales for particle sizing.

and consists of a large circle divided by crosshairs into quadrants, transparent and black reference circles 10  $\mu\text{m}$  and 25  $\mu\text{m}$  in diameter at 100 magnifications, and a linear scale graduated in 10- $\mu\text{m}$  increments. It is calibrated using a stage micrometer that is certified by either a domestic or international standard institution. A relative error of the linear scale of the graticule within  $\pm 2\%$  is acceptable. The large circle is designated the graticule field of view (GFOV).

Two illuminators are required. One is an episcopic brightfield illuminator internal to the microscope, the other is an external, focusable auxiliary illuminator that can be adjusted to give reflected oblique illumination at an angle of 10° to 20°.

The filter assembly for retaining particulate matter consists of a filter holder made of glass or other suitable material, and is equipped with a vacuum source and a suitable membrane filter.

The membrane filter is of suitable size, black or dark gray in color, nongridded or gridded, and 1.0  $\mu\text{m}$  or finer in nominal pore size.

#### General Precautions

The test is carried out under conditions limiting particulate matter, preferably in a laminar flow cabinet.

Very carefully wash the glassware and filter assembly used, except for the membrane filter, with a warm detergent solution, and rinse with abundant amounts of water to remove all traces of detergent. Immediately before use, rinse both sides of the membrane filter and the equipment from top to bottom, outside and then inside, with particle-free water.

In order to check that the environment is suitable for the test, that the glassware and the membrane filter are properly cleaned, and that the water to be used is particle-free, the following test is carried out: determine the particulate matter of a 50-mL volume of particle-free water according to the method described below. If more than 20 particles 10  $\mu\text{m}$  or larger in size or if more than 5 particles 25  $\mu\text{m}$  or larger in size are present within the filtration area, the precautions taken for the test are not sufficient. The preparatory steps must be repeated until the environment, glassware, membrane filter, and water are suitable for the test.

#### Method

Mix the contents of the samples by slowly inverting the container 20 times successively. If necessary, cautiously remove the sealing closure. Clean the outer surfaces of the container opening using a jet of particle-free water and remove the closure, avoiding any contamination of the contents.

For large-volume parenterals, single units are tested. For small-volume parenterals less than 25 mL in volume, the contents of 10 or more units are combined in a cleaned container; the test solution may be prepared by mixing the contents of a suitable number of vials and diluting to 25 mL with particle-free water or with an appropriate particle-free solvent when particle-free water is not suitable. Small-volume parenterals having a volume of 25 mL or more may be tested individually.

Powders for parenteral use are constituted with particle-free water or with an appropriate particle-free solvent when particle-free water is not suitable.

The number of test specimens must be adequate to provide a statistically sound assessment. For large-volume parenterals or for small-volume parenterals having a volume of 25 mL or more, fewer than 10 units may be tested, using an appropriate sampling plan.

Wet the inside of the filter holder fitted with the membrane filter with several mL of particle-free water. Transfer to the filtration funnel the total volume of a solution pool or of a single unit, and apply a vacuum. If needed, add stepwise a portion of the solution until the entire volume is filtered. After the last addition of solution, begin rinsing the inner walls of the filter holder by using a jet of particle-free water. Maintain the vacuum until the surface of the membrane filter is free from liquid. Place the membrane filter in a Petri dish, and allow the membrane filter to air-dry with the cover slightly ajar. After the membrane filter has been dried, place the Petri dish on the stage of the microscope, scan the entire membrane filter under the reflected light from the illuminating device, and count the number of particles that are equal to or greater than 10  $\mu\text{m}$  and the number of particles that are equal to or greater than 25  $\mu\text{m}$ . Alternatively, partial membrane filter count and determination of the total filter count by calculation is allowed. Calculate the mean number of particles for the preparation to be examined.

The particle sizing process with the use of the circular diameter graticule is carried out by estimating the equivalent diameter of the particle in comparison with the 10  $\mu\text{m}$  and 25  $\mu\text{m}$  reference circles on the graticule. Thereby the particles are not moved from their initial locations within the graticule field of view and are not superimposed on the reference circles for comparison. The inner diameter of the transparent graticule reference circles is used to size white and transparent particles, while dark particles are sized by using the outer diameter of the black opaque graticule reference circles.

In performing the Microscopic Particle Count Test, do not attempt to size or enumerate amorphous, semiliquid, or otherwise morphologically indistinct materials that have the appearance of a stain or discoloration on the membrane filter. These materials show little or no surface relief and present a gelatinous or film-like appearance. In such cases, the interpretation of enumeration may be aided by testing a sample of the solution by the Light Obscuration Particle Count Test.

#### Evaluation

For preparations supplied in containers with a nominal volume of more than 100 mL, apply the criteria of Test 2.A.

For preparations supplied in containers with a nominal volume of less than 100 mL, apply the criteria of Test 2.B.

For preparations supplied in containers with a nominal volume of 100 mL, apply the criteria of Test 2.B. [note—Test 2.A is used in the Japanese Pharmacopeia.]

Test 2.A (Solutions for parenteral infusion or solutions for injection supplied in containers with a nominal content of more than 100 mL)—The preparation complies with the test if the average number of particles present in the units tested does not exceed 12 per mL equal to or greater than 10  $\mu\text{m}$  and does not exceed 2 per mL equal to or greater than 25  $\mu\text{m}$ .

Test 2.B (Solutions for parenteral infusion or solutions for injection supplied in containers with a nominal content of less than 100 mL)—The preparation complies with the test if the average number of particles present in the units tested does not exceed 3000 per container equal to or greater than 10  $\mu\text{m}$  and does not exceed 300 per container equal to or greater than 25  $\mu\text{m}$ .

#### 789 PARTICULATE MATTER IN OPHTHALMIC SOLUTIONS

Particulate matter consists of mobile, randomly sourced, extraneous substances, other than gas bubbles, that cannot be quantitated by chemical analysis because of the small amount of material they represent and because of their heterogeneous composition. Ophthalmic solutions should be essentially free from particles that can be observed on visual inspection.

The tests described herein are physical tests performed for the purpose of enumerating extraneous particles within specific size ranges.

Every ophthalmic solution for which the monograph includes a test for Particulate matter is subject to the particulate matter limits set forth for the test being applied, unless otherwise specified in the individual monograph. When higher limits are appropriate, they will be specified in the individual monograph. Ophthalmic preparations that are suspensions, emulsions, or gels are exempt from these requirements, as are medical devices. Refer to the specific monograph when a question of test applicability occurs.

Light obscuration and microscopic procedures for the determination of particulate matter in ophthalmic solutions are identical to those for injections; therefore, where appropriate, [Particulate Matter in Injections](#) 788 is cross-referenced. This chapter provides a test approach in two stages. The ophthalmic solution is first tested by the light obscuration procedure (stage 1). If it fails to meet the prescribed limits, it must pass the microscopic procedure (stage 2) with its own set of test limits. Where for technical reasons the ophthalmic solution cannot be tested by light obscuration, microscopic testing may be used exclusively. Documentation is required, demonstrating that the light obscuration procedure is incapable of testing the ophthalmic solution or that it produces invalid results.

It is expected that most articles will meet the requirements on the basis of the light obscuration test alone; however, it may be necessary to test some articles by the light obscuration test followed by the microscopic test to reach a conclusion on conformance to requirements. Any product that is not a pure solution having a clarity and a viscosity approximating those of water may provide erroneous data when analyzed by the light obscuration counting method. Such materials may be analyzed by the microscopic counting method. In some instances, the viscosity of a material to be tested may be sufficiently high so as to preclude its analysis by either test method. In this event, a quantitative dilution with an appropriate diluent may be made to decrease viscosity, as necessary, to allow the analysis to be performed.

In the tests described below, the results obtained by examining a discrete unit or group of units for particulate matter cannot be extrapolated with certainty to other units that remain untested. Thus, sampling plans based on known operational factors must be developed if valid inferences are to be drawn from observed data to characterize the level of particulate matter in a large group of units. Sampling plans need to be based on consideration of product volume, particle numbers historically found to be present in comparison to limits, particle size distribution of particles present, and variability of particle counts between units.

#### LIGHT OBSCURATION PARTICLE COUNT TEST

This test applies to ophthalmic solutions, including solutions constituted from sterile solids, for which a test for Particulate matter is specified in the individual monograph. The test counts suspended particles that are solid or liquid.

Test Apparatus, Instrument Standardization, Test Environment, Test Procedure, and Calculations— Proceed as directed for Light Obscuration Particle Count Test under [Particulate Matter in Injections](#) 788.

Interpretation— The ophthalmic solution meets the requirements of the test if the average number of particles present in the units tested does not exceed the appropriate value listed in [Table 1](#). If the average number of particles exceeds the limit, test the article by the Microscopic Particle Count Test.

Table 1. Light Obscuration Test Particle Count

	Diameter	
	$\geq 10 \mu\text{m}$	$\geq 25 \mu\text{m}$
Number of particles	50 per mL	5 per mL

#### MICROSCOPIC PARTICLE COUNT TEST

Some articles cannot be tested meaningfully by light obscuration. In such cases, individual monographs clearly specify that only a microscopic particle count is to be performed. The

Microscopic particle count test enumerates subvisible, essentially solid, particulate matter in ophthalmic solutions, after collection on a microporous membrane filter. Some ophthalmic solutions, such as solutions that do not filter readily because of their high viscosity, may be exempted from analysis using the microscopic test.

When performing the microscopic test, do not attempt to size or enumerate amorphous, semiliquid, or otherwise morphologically indistinct materials that have the appearance of a stain or discoloration on the membrane surface. These materials show little or no surface relief and present a gelatinous or film-like appearance. Because in solution this material consists of units on the order of 1  $\mu\text{m}$  or less, which may be counted only after aggregation or deformation on an analytical membrane, interpretation of enumeration may be aided by testing a sample of the solution by the light obscuration particle count method.

Test Apparatus, Test Environment, Test Procedure, and Enumeration of Particles— Proceed as directed for Microscopic Particle Count Test under [Particulate Matter in Injections](#) (788).

Interpretation— The ophthalmic solution meets the requirements of the test if the average number of particles present in the units tested does not exceed the appropriate value listed in [Table 2](#).

Table 2. Microscopic Method Particle Count

	Diameter		
	$\geq 10 \mu\text{m}$	$\geq 25 \mu\text{m}$	$\geq 50 \mu\text{m}$
Number of particles	50 per mL	5 per mL	2 per mL

(791) pH

For compendial purposes, pH is defined as the value given by a suitable, properly standardized, potentiometric instrument (pH meter) capable of reproducing pH values to 0.02 pH unit using an indicator electrode sensitive to hydrogen-ion activity, the glass electrode, and a suitable reference electrode. The instrument should be capable of sensing the potential across the electrode pair and, for pH standardization purposes, applying an adjustable potential to the circuit by manipulation of "standardization," "zero," "asymmetry," or "calibration" control, and should be able to control the change in millivolts per unit change in pH reading through a "temperature" and/or "slope" control. Measurements are made at  $25 \pm 2^\circ$ , unless otherwise specified in the individual monograph or herein.

The pH scale is defined by the equation:

$$\text{pH} = \text{pHs} + (E - ES) / k$$

in which E and ES are the measured potentials where the galvanic cell contains the solution under test, represented by pH, and the appropriate Buffer Solution for Standardization, represented by pHs, respectively. The value of k is the change in potential per unit change in pH and is theoretically  $[0.05916 + 0.000198(t - 25^\circ)]$  volts at any temperature t.

It should be emphasized that the definitions of pH, the pH scale, and the values assigned to the Buffer Solutions for Standardization are for the purpose of establishing a practical, operational system so that results may be compared between laboratories. The pH values thus measured do not correspond exactly to those obtained by the definition,  $\text{pH} = -\log a\text{H}^+$ . So long as the solution being measured is sufficiently similar in composition to the buffer used for standardization, the operational pH corresponds fairly closely to the theoretical pH. Although no claim is made with respect to the suitability of the system for measuring hydrogen-ion activity or concentration, the values obtained are closely related to the activity of the hydrogen-ion in aqueous solutions.

Where a pH meter is standardized by use of an aqueous buffer and then used to measure the "pH" of a nonaqueous solution or suspension, the ionization constant of the acid or base, the dielectric constant of the medium, the liquid-junction potential (which may give rise to errors of approximately 1 pH unit), and the hydrogen-ion response of the glass electrode are all changed. For these reasons, the values so obtained with solutions that are only partially aqueous in character can be regarded only as apparent pH values.

#### BUFFER SOLUTIONS FOR STANDARDIZATION OF THE pH METER

Buffer Solutions for Standardization are to be prepared as directed in the accompanying table.\* Buffer salts of requisite purity can be obtained from the National Institute of Science and Technology. Solutions may be stored in hard glass or polyethylene bottles fitted with a tight closure or carbon dioxide-absorbing tube (soda lime). Fresh solutions should be prepared at intervals not to exceed 3 months using carbon dioxide-free water. The table indicates the pH of the buffer solutions as a function of temperature. The instructions presented here are for the preparation of solutions having the designated molal (m) concentrations. For convenience, and to facilitate their preparation, however, instructions are given in terms of dilution to a 1000-mL volume rather than specifying the use of 1000 g of solvent, which is the basis of the molality system of solution concentration. The indicated quantities cannot be computed simply without additional information.

#### pH Values of Buffer Solutions for Standardization

Temperature, $^\circ\text{C}$	Potassium Tetraoxalate, 0.05 m	Potassium Biphthalate, 0.05 m	Equimolar Phosphate, 0.05 m	Sodium Tetraborate, 0.01 m	Calcium Hydroxide, Saturated at $25^\circ$
10	1.67	4.00	6.92	9.33	13.00
15	1.67	4.00	6.90	9.28	12.81

45	1.70	4.05	6.83	9.04	11.84
50	1.71	4.06	6.83	9.01	11.71
55	1.72	4.08	6.83	8.99	11.57
60	1.72	4.09	6.84	8.96	11.45

Potassium Tetraoxalate, 0.05 m— Dissolve 12.61 g of  $\text{KH}_3(\text{C}_2\text{O}_4)_2 \cdot 2\text{H}_2\text{O}$  in water to make 1000 mL.

Potassium Biphthalate, 0.05 m— Dissolve 10.12 g of  $\text{KHC}_8\text{H}_4\text{O}_4$ , previously dried at  $110^\circ$  for 1 hour, in water to make 1000 mL.

Equimolar Phosphate, 0.05 m— Dissolve 3.53 g of Na<sub>2</sub>HPO<sub>4</sub> and 3.39 g of KH<sub>2</sub>PO<sub>4</sub>, each previously dried at 120° for 2 hours, in water to make 1000 mL.

Sodium Tetraborate, 0.01 m— Dissolve 3.80 g of Na<sub>2</sub>B<sub>4</sub>O<sub>7</sub>·10H<sub>2</sub>O in water to make 1000 mL. Protect from absorption of carbon dioxide.

Calcium Hydroxide, saturated at 25°— Shake an excess of calcium hydroxide with water, and decant at 25° before use. Protect from absorption of carbon dioxide.

Because of variations in the nature and operation of the available pH meters, it is not practicable to give universally applicable directions for the potentiometric determinations of pH. The general principles to be followed in carrying out the instructions provided for each instrument by its manufacturer are set forth in the following paragraphs. Examine the electrodes and, if present, the salt bridge prior to use. If necessary, replenish the salt bridge solution, and observe other precautions indicated by the instrument or electrode manufacturer.

To standardize the pH meter, select two Buffer Solutions for Standardization whose difference in pH does not exceed 4 units and such that the expected pH of the material under test falls between them. Fill the cell with one of the Buffer Solutions for Standardization at the temperature at which the test material is to be measured. Set the "temperature" control at the temperature of the solution, and adjust the calibration control to make the observed pH value identical with that tabulated. Rinse the electrodes and cell with several portions of the second Buffer Solution for Standardization, then fill the cell with it, at the same temperature as the material to be measured. The pH of the second buffer solution is within ±0.07 pH unit of the tabulated value. If a larger deviation is noted, examine the electrodes and, if they are faulty, replace them. Adjust the "slope" or "temperature" control to make the observed pH value identical with that tabulated. Repeat the standardization until both Buffer Solutions for Standardization give observed pH values within 0.02 pH unit of the tabulated value without further adjustment of the controls. When the system is functioning satisfactorily, rinse the electrodes and cell several times with a few portions of the test material, fill the cell with the test material, and read the pH value. Use carbon dioxide-free water (see Water in the section [Reagents, Indicators, and Solutions](#)) for solution or dilution of test material in pH determinations. In all pH measurements, allow a sufficient time for stabilization.

Where approximate pH values suffice, indicators and test papers (see Indicators and Indicator Test Papers, in the section [Reagents, Indicators, and Solutions](#)) may be suitable.

For a discussion of buffers, and for the composition of standard buffer solutions called for in compendial tests and assays, see Buffer Solutions in the section [Reagents, Indicators, and Solutions](#).

\* Commercially available buffer solutions for pH meter standardization, standardized by methods traceable to the National Institute of Standards and Technology (NIST), labeled with a pH value accurate to 0.01 pH unit may be used. For standardization solutions having a pH lower than 4, a labeled accuracy of 0.02 is acceptable. Solutions prepared from ACS reagent grade materials or other suitable materials, in the stated quantities, may be used provided the pH of the resultant solution is the same as that of the solution prepared from the NIST certified material.

Auxiliary Information— Please [check for your question in the FAQs](#) before contacting USP.

#### 795 PHARMACEUTICAL COMPOUNDING—NONSTERILE PREPARATIONS

For the purposes of this chapter, the pharmacist or other licensed health care professional responsible for preparing the compounded preparations is referred to as "compounder".

Compounding is an integral part of pharmacy practice and is essential to the provision of health care. The purpose of this chapter and applicable monographs on formulation is to help define what constitutes good compounding practices and to provide general information to enhance the compounder's ability in the compounding facility to extemporaneously compound preparations that are of acceptable strength, quality, and purity.

Compounding is different from manufacturing, which is guided by GMPs (see [Good Manufacturing Practices for Bulk Pharmaceutical Excipients](#)). Some of the characteristics or criteria that differentiate compounding from manufacturing include the existence of specific practitioner–patient–compounder relationships; the quantity of medication prepared in anticipation of receiving a prescription or a prescription order; and the conditions of sale, which are limited to specific prescription orders.

The pharmacist's responsibilities in compounding drug preparations are to dispense the finished preparation in accordance with a prescription or a prescriber's order or intent and to dispense those preparations in compliance with the requirements established by the Boards of Pharmacy and other regulatory agencies. Compounders must be familiar with statutes and regulations that govern compounding because these requirements vary from state to state.

The compounder is responsible for compounding preparations of acceptable strength, quality, and purity with appropriate packaging and labeling in accordance with good compounding practices (see [Good Compounding Practices](#)), official standards, and relevant scientific data and information. Compounders engaging in compounding should have to continually expand their compounding knowledge by participating in seminars, studying appropriate literature, and consulting colleagues.

#### RESPONSIBILITY OF THE COMPOUNDER

The compounder is responsible for ensuring that the quality is built into the compounded preparations of products, with key factors including at least the following general principles.

(See also [Good Compounding Practices](#).)

1. Personnel are capable and qualified to perform their assigned duties.
2. Ingredients used in compounding have their expected identity, quality, and purity.
3. Compounded preparations are of acceptable strength, quality, and purity, with appropriate packaging and labeling, and prepared in accordance with good compounding practices, official standards, and relevant scientific data and information.
4. Critical processes are validated to ensure that procedures, when used, will consistently result in the expected qualities in the finished preparation.
5. The compounding environment is suitable for its intended purpose.
6. Appropriate stability evaluation is performed or determined from the literature for establishing reliable beyond-use dating to ensure that the finished preparations have their expected potency, purity, quality, and characteristics, at least until the labeled beyond-use date.
7. There is assurance that processes are always carried out as intended or specified and are under control.
8. Compounding conditions and procedures are adequate for preventing errors.
9. Adequate procedures and records exist for investigating and correcting failures or problems in compounding, testing, or in the preparation itself.

#### COMPOUNDING ENVIRONMENT

##### Facilities

Areas designated for compounding have adequate space for the orderly placement of equipment and materials to prevent mixups between ingredients, containers, labels, in-process materials, and finished preparations. The compounding area is also to be designed, arranged, used, and maintained to prevent adventitious cross-contamination. Areas used for sterile preparations are to be separated and distinct from the nonsterile compounding area (see Environmental Quality and Control under [Pharmaceutical Compounding—Sterile Preparations](#)). The entire compounding area is to be well-lighted. Heating, ventilation, and air conditioning systems are to be controlled to avoid decomposition of chemicals (see Storage Temperature under Preservation, Packaging, Storage, and Labeling in the General Notices and Requirements and the manufacturers' labeled storage conditions). Storage areas provide an environment suitably controlled to ensure quality and stability of bulk chemicals and finished preparations.

Potable water is to be supplied for hand and equipment washing. This water meets the standards prescribed in the EPA's National Primary Drinking Water Regulations (40 CFR Part 141). Purified Water must be used for compounding nonsterile drug preparations when formulations indicate the inclusion of water. Purified Water must also be used for rinsing equipment and utensils. In those cases when a water is used to prepare a sterile preparation, Water for Injection, Sterile Water for Injection, or Bacteriostatic Water for Injection must be used (see [Water for Pharmaceutical Purposes](#) (1231) and [Pharmaceutical Compounding—Sterile Preparations](#) (797)).

Compounding areas are to be maintained in a clean and sanitary condition. Adequate washing facilities are to be provided, including hot and cold water, soap or detergent, and air dryers or single-service towels. Sewage, trash, and other refuse in the compounding area is to be disposed of in a safe, sanitary, and timely manner. Equipment is to be thoroughly cleaned promptly after use to avoid cross-contamination of ingredients and preparations. Special precautions are to be taken to clean equipment and compounding areas meticulously after compounding preparations that contain allergenic ingredients (e.g., sulfonamides or penicillins).

#### Equipment

Equipment is to be of appropriate design and size for compounding and suitable for the intended uses. The types and sizes of equipment will depend on the dosage forms and the quantities compounded (see [Weights and Balances](#) (41), [Prescription Balances and Volumetric Apparatus](#) (1176), and equipment manufacturers' instruction manuals). All equipment is to be constructed so that surfaces that contact pharmaceutical components, in-process materials, or finished preparations are not reactive, additive, or adsorptive to avoid altering the safety, identity, strength, quality, or purity of the preparation. The use of micropipets, electronic or analytical balances, or triturations or dilutions shall be considered when needed quantities are too small to accurately measure with standard equipment required by a state Board of Pharmacy. Equipment and accessories used in compounding are to be inspected, maintained, cleaned, and validated at appropriate intervals to ensure the accuracy and reliability of their performance.

#### STABILITY OF COMPOUNDED PREPARATIONS

"Stability" is defined as the extent to which a preparation retains, within specified limits, and throughout its period of storage and use, the same properties and characteristics that it possessed at the time of compounding. See the table Criteria for Acceptable Levels of Stability under [Stability Considerations in Dispensing Practice](#) (1191).

The compounder must avoid formulation ingredients and processing conditions that would result in a potentially toxic or ineffective preparation. The compounder's knowledge of the chemical reactions by which drugs degrade provides a means for establishing conditions under which the rate of degradation is minimized. The factors that influence the stability of compounded preparations are generally the same as those for manufactured drug products (see [Factors Affecting Product Stability and Responsibility of the Pharmacist](#) under [Stability Considerations in Dispensing Practice](#) (1191)).

#### Primary Packaging

Compounded preparations should be packaged in containers meeting USP standards (see [Containers under Preservation, Packaging, Storage, and Labeling in the General Notices and Requirements](#), [Containers—Plastics](#) (661), and [Containers—Performance Testing](#) (671)). The container used depends on the physical and chemical properties of the compounded preparation. Container-drug interaction is to be considered with substances such as phenolic compounds and sorptive materials (e.g., polypeptides and proteins).

#### Sterility

Assurance of sterility in a compounded sterile preparation is mandatory. Compounding and packaging of sterile drugs, such as ophthalmic solutions, will require strict adherence to guidelines presented in the general test chapter [Pharmaceutical Compounding—Sterile Preparations](#) (797) and in the manufacturers' labeling instructions.

#### Stability Criteria and Beyond-Use Dating

The beyond-use date is the date after which a compounded preparation is not to be used and is determined from the date the preparation is compounded. Because compounded preparations are intended for administration immediately or following short-term storage, their beyond-use dates may be assigned based on criteria different from those applied to assigning expiration dates to manufactured drug products.

Compounders are to consult and apply drug-specific and general stability documentation and literature when available, and are to consider the nature of the drug and its degradation mechanism, the container in which it is packaged, the expected storage conditions, and the intended duration of therapy when assigning a beyond-use date (see [Expiration Date and Beyond-Use Date under Labeling in the General Notices and Requirements](#)). Beyond-use dates are to be assigned conservatively. When using manufactured solid dosage forms to prepare a solution or aqueous suspension, the compounder is also to consider factors such as hydrolysis and the freeze-thaw property of the final preparation before assigning a beyond-use date. In assigning a beyond-use date for a compounded drug preparation, in addition to using all available stability information, the compounder is also to use his or her pharmaceutical education and experience.

When a manufactured product is used as the source of active ingredient for a nonsterile compounded preparation, the product expiration date cannot be used to extrapolate directly a beyond-use date for the compounded preparation. However, a compounder may refer to the literature or to the manufacturer for stability information. The compounder may also refer to applicable publications to obtain stability, compatibility, and degradation information on ingredients. All stability data must be carefully interpreted in relation to the actual compounded formulation.

At all steps in the compounding, dispensing, and storage process, the compounder is to observe the compounded drug preparation for signs of instability. For more specific details of some of the common physical signs of deterioration, see [Observing Products for Evidence of Instability](#) under [Stability Considerations in Dispensing Practice](#) (1191). However, excessive chemical degradation and other drug concentration loss due to reactions may be invisible more often than they are visible.

In the absence of stability information that is applicable to a specific drug and preparation, the following maximum beyond-use dates are recommended for nonsterile compounded drug preparations<sup>4</sup> that are packaged in tight, light-resistant containers and stored at controlled room temperature unless otherwise indicated (see [Preservation, Packaging, Storage, and Labeling in the General Notices and Requirements](#)).

#### For Nonaqueous Liquids and Solid Formulations—

Where the Manufactured Drug Product is the Source of Active Ingredient— The beyond-use date is not later than 25% of the time remaining until the product's expiration date or 6 months, whichever is earlier.

Where a USP or NF Substance is the Source of Active Ingredient— The beyond-use date is not later than 6 months.

For Water-Containing Formulations (prepared from ingredients in solid form)— The beyond-use date is not later than 14 days for liquid preparations when stored at cold temperatures between 2° and 8° (36° and 46° F).

For All Other Formulations— The beyond-use date is not later than the intended duration of therapy or 30 days, whichever is earlier. These beyond-use date limits may be exceeded when there is supporting valid scientific stability information that is directly applicable to the specific preparation (i.e., the same drug concentration range, pH, excipients, vehicle, water content, etc.). See also the beyond-use dating information in the Labeling section under [Repackaging Into Single-Unit Containers and Unit-Dose Containers for Nonsterile Solid and Liquid Dosage Forms](#) (681).

#### Beyond-Use Labeling

Federal law requires that manufactured drug products be labeled with an expiration date. Some state laws may require a beyond-use date. The label on the container or package of an official compounded preparation must bear a beyond-use date. Good compounding practice dictates beyond-use labeling for all compounded preparations.

#### DEFINITIONS

For purposes of this chapter, the following terms shall have these meanings.

preparation is a drug dosage form, a dietary supplement, or a finished device. It is the finished or partially finished preparation of one or more substances formulated for use on or for

the patient or consumer (see General Notices and Requirements).

official substance includes an active drug entity, a dietary supplement, or a pharmaceutic ingredient (see also NF 23) or a component of a finished device.

active ingredient usually refers to chemicals, substances, or other components of articles intended for use in the diagnosis, cure, mitigation, treatment, or prevention of diseases in humans or other animals or for use as dietary supplements.

added substances are ingredients that are necessary to prepare the preparation but are not intended or expected to cause a human pharmacologic response if administered alone in the amount or concentration contained in a single dose of the compounded preparation. The term added substances is usually used synonymously with the terms inactive ingredients, excipients, and pharmaceutic ingredients.

#### INGREDIENT SELECTION

##### Sources

Official compounded preparations are prepared from ingredients that meet requirements of the compendial monograph for those individual ingredients for which monographs are provided.

A USP or an NF grade substance is the preferred source of ingredients for compounding all other preparations. If that is not available, or when food, cosmetics, or other substances are or must be used, then the use of another high-quality source, such as analytical reagent (AR), certified American Chemical Society (ACS), or Food Chemicals Codex (FCC) grade, is an option for professional judgment. For any substance used in compounding not purchased from a registered drug manufacturer, the compounder must establish purity and safety by reasonable means, which may include lot analysis, manufacturer reputation, or reliability of source.

A manufactured drug product may be a source of active ingredient. Only manufactured drugs from containers labeled with a batch control number and a future expiration date are acceptable as a potential source of active ingredients. When compounding with manufactured drug products, the compounder must consider all ingredients present in the drug product relative to the intended use of the compounded preparation.

A compounder may not compound a drug preparation that appears on the FDA list of drug products withdrawn or removed from the market for safety reasons.

##### Compounding Nondrug Requirements

If the preparation is intended for use as a dietary or nutritional supplement (to supplement the diet) or cosmetic (e.g., to beautify), then the compounder must adhere to [Good Compounding Practices \(1075\)](#) and to this chapter, and must comply with any federal and state requirements.

#### CHECKLIST FOR ACCEPTABLE STRENGTH, QUALITY, AND PURITY

The following questions are to be considered carefully before compounding.

1. Have the physical and chemical properties and medicinal, dietary, and pharmaceutical uses of the drug substances been reviewed?
2. Are the quantity and quality of each active ingredient identifiable?
3. Will the active ingredients be effectively absorbed, locally or systemically according to the prescribed purpose, from the preparation and route of administration?
4. Are there added substances (see Definitions), confirmed or potentially present from manufactured products, that may be expected to cause an allergic reaction, irritation, toxicity, or undesirable organoleptic response from the patient? Are there added substances (see Definitions), confirmed or potentially present, that may be unfavorable (e.g., unsuitable pH or inadequate solubility)?
5. Were all calculations and measurements confirmed to ensure that the preparation will be compounded accurately (see [Pharmaceutical Calculations in Prescription Compounding \(1160\)](#))?

#### COMPOUNDED PREPARATIONS

The term compounded preparations includes the terms compounded dosage forms, compounded drugs, and compounded formulations, and means finished forms that are prepared by or under the direct supervision of a licensed compounder.

When controlled substances are used, check with state and federal authorities concerning their policies. Unless otherwise indicated or appropriate, compounded preparations are to be prepared to ensure that each preparation shall contain not less than 90.0% and not more than 110.0% of the theoretically calculated and labeled quantity of active ingredient per unit weight or volume and not less than 90.0% and not more than 110.0% of the theoretically calculated weight or volume per unit of the preparation. Compounded preparations include, but are not restricted to, the following pharmaceutical dosage forms described under [Pharmaceutical Dosage Forms \(1151\)](#).

##### Capsules, Powders, Lozenges, and Tablets

When compounding these dosage forms, the compounder is to prepare an amount of the total formulation sufficient to allow the prescribed amount or quantity to be accurately dispensed. Selected practices and precautions for compounding these dosage forms include the following:

- reducing solid ingredients to the smallest reasonable particle size;
- implementing appropriate checks to ensure that all ingredients are blended to achieve a homogeneous mixture;
- monitoring humidity if moisture might cause hydrolysis, dosage form adhesion to containers, or softening or partial dissolution of capsule shells;
- accurately performing weighings to ensure that each unit shall be not less than 90% and not more than 110% of the theoretically calculated weight for each unit [note—Preparations classified as dietary supplements are required by the U.S. Food and Drug regulations to be not less than 100% of the declared potency.]; and
- packaging dosage units according to container specifications for capsules and tablets of the specific active ingredient unless specified otherwise in individual monographs (see [Containers—Glass \(660\)](#) and [Containers—Plastic \(661\)](#)).

##### Emulsions, Solutions, and Suspensions

When compounding these dosage forms, the compounder is to prepare a 2% to 3% excess amount of the total formulation to allow the prescribed amount to be accurately dispensed. Selected practices and precautions for compounding these dosage forms include the following:

- For single-unit containers, the weight of each filled container, corrected for tare weight, shall be the equivalent of not less than 100% and not more than 110% of the labeled volume.
- Aqueous suspensions are prepared by levigating the powder mixture to a smooth paste with an appropriate wetting agent. This paste is converted to a free-flowing fluid by adding adequate vehicle. Successive portions of the vehicle are used to wash the mortar, or other vessel, to transfer the suspension quantitatively to a calibrated dispensing bottle or graduate. The preparation may be homogenized to ensure a uniform final dispersion.
  - Reducing solid ingredients to the smallest reasonable particle size.
- Solutions shall contain no visible undissolved matter when dispensed. [note—An exception may occur with supersaturated solutions such as Potassium Iodide Oral Solution.]
  - Emulsions and suspensions are labeled, "Shake well before using."

##### Suppositories

When compounding suppositories, the compounder is to prepare an excess amount of total formulation to allow the prescribed quantity to be accurately dispensed. Selected practices and precautions for compounding these dosage forms include the following:

- not using ingredients that are caustic or irritating, and thoroughly comminute solids that are abrasive to the mucous membranes;

- selecting a base that allows active ingredients to provide the intended local or systemic therapeutic effect;
- reducing solid ingredients to the smallest reasonable particle size; and
- weighing a representative number of suppositories to ensure that each is not less than 90% and not more than 110% of the average weight of all suppositories in the batch.

#### Creams, Topical Gels, Ointments, and Pastes

When compounding semisolid dosage forms, the compounder is to prepare an excess amount of total formulation to allow the prescribed quantity to be accurately dispensed. Selected practices and precautions for compounding these dosage forms include the following:

- not using ingredients that are caustic, irritating, or allergenic to the skin or other application sites unless they are necessary for a treatment;
- selecting a base or vehicle that allows active ingredients to provide the intended local or systemic therapeutic effect;
- reducing solid ingredients to the smallest reasonable particle size;
- geometrically incorporating the active ingredients with the added substances to achieve a uniform liquid or solid dispersion in the dosage form; and
- observing the uniformity of the dispersion by spreading a thin film of finished formulation on a flat transparent surface (e.g., clear glass ointment slab).

#### COMPOUNDING PROCESS

The compounders are to consider using the following steps to minimize error and maximize the prescriber's intent.

1. Judge the suitability of the prescription to be compounded in terms of its safety and intended use. Determine what legal limitations, if any, are applicable.
2. Perform necessary calculations to establish the amounts of ingredients needed (see [Pharmaceutical Calculations in Prescription Compounding \(1160\)](#)).
3. Identify equipment needed.
4. Don the proper attire and wash hands.
5. Clean the compounding area and needed equipment.
6. Only one prescription should be compounded at one time in a specified compounding area.
7. Assemble all necessary materials to compound the prescription.
8. Compound the preparation following the formulation record or prescription (see Compounding Records and Documents below), according to the art and science of pharmacy.
9. Assess weight variation, adequacy of mixing, clarity, odor, color, consistency, and pH as appropriate.
10. Annotate the compounding log, and describe the appearance of the formulation.
11. Label the prescription containers to include the following items: a) the name of the preparation; b) the internal identification number; c) the beyond-use date (see Beyond-Use Labeling); d) the initials of the compounder who prepared the label; e) any storage requirements; and f) any other statements required by law.
12. Sign and date the prescription affirming that all procedures were carried out to ensure uniformity, identity, strength, quantity, and purity.
13. Thoroughly and promptly clean all equipment, and store properly.

#### COMPOUNDING RECORDS AND DOCUMENTS

All compounders who dispense prescriptions must comply with the record keeping requirements of their individual states. If the compounder compounds a preparation according to the manufacturer's labeling instructions, then further documentation is not required. All other compounded preparations require further documentation. Such compounding documents are to list the ingredients and the quantity of each in the order of the compounding process.

The objective of the documentation is to allow another compounder to reproduce the identical prescription at a future date. The formulation record provides a consistent source document for preparing the preparation (recipe), and the compounding record documents the actual ingredients in the preparation and the person responsible for the compounding activity. These records are to be retained for the same period of time that is required for any prescription under state law. The record may be a copy of the prescription in written or machine readable form that includes a formulation record, a compounding record, and a Material Safety Data Sheets (MSDS) file.

##### Formulation Record

The formulation record is a file of individually compounded preparations. This record must list the name, strength, and dosage form of the preparation compounded, all ingredients and their quantities, equipment needed to prepare the preparation, when appropriate, and mixing instructions. Mixing instructions should include the order of mixing, mixing temperatures or other environmental controls, such as the duration of mixing, and other factors pertinent to the replication of the preparation as compounded. The formulation record must include an assigned beyond-use date, the container used in dispensing, the storage requirements, and any quality control procedures.

##### Compounding Record

The compounding record contains documentation of the name and strength of the compounded preparation, the formulation record reference for the preparation, and the sources and lot numbers of ingredients. The compounding record also includes information on the total number of dosage units compounded, the name of the person who prepared the preparation and the name of the compounder who approved the preparation, the date of preparation, the assigned internal identification number or the prescription number and an assigned beyond-use date, and the prescription number. For all compounded preparations, results of quality control procedures are to be recorded (e.g., weight range of filled capsules). When compounding problems occur with preparations prepared according to USP compounding monographs, the compounder must complete a USP Monograph Experience Reporting Form, and submit the form to USP for evaluation.

##### MSDS File

MSDS are to be readily accessible to all employees working with drug substances or bulk chemicals located on the compounding facility premises. Employees are to be instructed on how to retrieve and interpret needed information.

#### QUALITY CONTROL

The safety, quality, and performance of compounded preparations depend on correct ingredients and calculations, accurate and precise measurements, appropriate formulation conditions and procedures, and prudent pharmaceutical judgment. As a final check, the compounder is to review each procedure in the compounding process. To ensure accuracy and completeness, the compounder is to observe the finished preparation to ensure that it appears as expected and is to investigate any discrepancies and take appropriate corrective action before the prescription is dispensed to the patient (see the Checklist for Acceptable Strength, Quality, and Purity, the appropriate pharmaceutical dosage form under Compounded Preparations, and the steps under Compounding Process).

#### VERIFICATION

Compounding procedures that are routinely performed, including batch compounding, shall be completed and verified according to written procedures. The act of verification of a compounding procedure involves checking to ensure that calculations, weighing and measuring, order of mixing, and compounding techniques were appropriate and accurately performed.

#### PATIENT COUNSELING

The patient or the patient's agent should be counseled about proper use, storage, and evidence of instability in the compounded preparation at the time of dispensing (see Responsibility of the Pharmacist under [Stability Considerations in Dispensing Practice \(1191\)](#)).

1 For guidelines applicable to dating sterile compounded preparations, see Storage and Beyond-Use Dating under [Pharmaceutical Compounding—Sterile Preparations](#) (797).

## 797 PHARMACEUTICAL COMPOUNDING—STERILE PREPARATIONS

### INTRODUCTION

The objective of this chapter is to describe conditions and practices to prevent harm, including death, to patients that could result from (1) microbial contamination (nonsterility), (2) excessive bacterial endotoxins, (3) variability in the intended strength of correct ingredients that exceeds either monograph limits for official articles (see “official” and “article” in the General Notices and Requirements) or 10% for nonofficial articles, (4) unintended chemical and physical contaminants, and (5) ingredients of inappropriate quality in compounded sterile preparations (CSPs). Contaminated CSPs are potentially most hazardous to patients when administered into body cavities, central nervous and vascular systems, eyes, and joints, and when used as baths for live organs and tissues. When CSPs contain excessive bacterial endotoxins (see [Bacterial Endotoxins Test](#) (85)), they are potentially most hazardous to patients when administered into the central nervous system.

Despite the extensive attention in this chapter to the provision, maintenance, and evaluation of air quality, the avoidance of direct or physical contact contamination is paramount. It is generally acknowledged that direct or physical contact of critical sites of CSPs with contaminants, especially microbial sources, poses the greatest probability of risk to patients. Therefore, compounding personnel must be meticulously conscientious in precluding contact contamination of CSPs both within and outside ISO Class 5 (see [Table 1](#)) areas.

To achieve the above five conditions and practices, this chapter provides minimum practice and quality standards for CSPs of drugs and nutrients based on current scientific information and best sterile compounding practices. The use of technologies, techniques, materials, and procedures other than those described in this chapter is not prohibited so long as they have been proven to be equivalent or superior with statistical significance to those described herein. The standards in this chapter do not pertain to the clinical administration of CSPs to patients via application, implantation, infusion, inhalation, injection, insertion, instillation, and irrigation, which are the routes of administration. Four specific categories of CSPs are described in this chapter: low-risk level, medium-risk level, and high-risk level, and immediate use. Sterile compounding differs from nonsterile compounding (see [Pharmaceutical Compounding—Nonsterile Preparations](#) (795) and [Good Compounding Practices](#) (1075)) primarily by requiring the maintenance of sterility when compounding exclusively with sterile ingredients and components (i.e., with immediate-use CSPs, low-risk level CSPs, and medium-risk level CSPs) and the achievement of sterility when compounding with nonsterile ingredients and components (i.e., with high-risk level CSPs). Some differences between standards for sterile compounding in this chapter and those for nonsterile compounding in [Pharmaceutical Compounding—Nonsterile Preparations](#) (795) include, but are not limited to, ISO-classified air environments (see [Table 1](#)); personnel garbing and gloving; personnel training and testing in principles and practices of aseptic manipulations and sterilization; environmental quality specifications and monitoring; and disinfection of gloves and surfaces of ISO Class 5 (see [Table 1](#)) sources.

Table 1. ISO Classification of Particulate Matter in Room Air (limits are in particles of 0.5  $\mu$ m and larger per cubic meter [current ISO] and cubic feet [former Federal Standard No. 209E, FS 209E]).\*

Class Name		Particle Count	
ISO Class	U.S. FS 209E	ISO, m <sup>3</sup>	FS 209E, ft <sup>3</sup>
3	Class 1	35.2	1
4	Class 10	352	10
5	Class 100	3,520	100
6	Class 1,000	35,200	1,000
7	Class 10,000	352,000	10,000
8	Class 100,000	3,520,000	100,000

\* Adapted from former Federal Standard No. 209E, General Services Administration, Washington, DC, 20407 (September 11, 1992) and ISO 14644-1:1999, Cleanrooms and associated controlled environments—Part 1: Classification of air cleanliness. For example, 3,520 particles of 0.5  $\mu$ m per m<sup>3</sup> or larger (ISO Class 5) is equivalent to 100 particles per ft<sup>3</sup> (Class 100) (1 m<sup>3</sup> = 35.2 ft<sup>3</sup>).

The standards in this chapter are intended to apply to all persons who prepare CSPs and all places where CSPs are prepared (e.g., hospitals and other healthcare institutions, patient treatment clinics, pharmacies, physicians' practice facilities, and other locations and facilities in which CSPs are prepared, stored, and transported). Persons who perform sterile compounding include pharmacists, nurses, pharmacy technicians, and physicians. These terms recognize that most sterile compounding is performed by or under the supervision of pharmacists in pharmacies and also that this chapter applies to all healthcare personnel who prepare, store, and transport CSPs. For the purposes of this chapter, CSPs include any of the following:

1. Compounded biologics, diagnostics, drugs, nutrients, and radiopharmaceuticals, including but not limited to the following dosage forms that must be sterile when they are administered to patients: aqueous bronchial and nasal inhalations, baths and soaks for live organs and tissues, injections (e.g., colloidal dispersions, emulsions, solutions, suspensions), irrigations for wounds and body cavities, ophthalmic drops and ointments, and tissue implants.
2. Manufactured sterile products that are either prepared strictly according to the instructions appearing in manufacturers' approved labeling (product package inserts) or prepared differently than published in such labeling. [note—The FDA states that “Compounding does not include mixing, reconstituting, or similar acts that are performed in accordance with the directions contained in approved labeling provided by the product's manufacturer and other manufacturer directions consistent with that labeling” [21 USC 321 (k) and (m)]. However, the FDA-approved labeling (product package insert) rarely describes environmental quality (e.g., ISO Class air designation, exposure durations to non-ISO classified air, personnel garbing and gloving, and other aseptic precautions by which sterile products are to be prepared for administration). Beyond-use exposure and storage dates or times (see General Notices and Requirements and [Pharmaceutical Compounding—Nonsterile Preparations](#) (795)) for sterile products that have been either opened or prepared for administration are not specified in all package inserts for all sterile products. Furthermore, when such durations are specified, they may refer to chemical stability and not necessarily to microbiological purity or safety.]

### ORGANIZATION OF THIS CHAPTER

The sections in this chapter are organized to facilitate the practitioner's understanding of the fundamental accuracy and quality practices for preparing CSPs. They provide a foundation for the development and implementation of essential procedures for the safe preparation of low-risk, medium-risk, and high-risk level CSPs and immediate-use CSPs, which are classified according to the potential for microbial, chemical, and physical contamination. The chapter is divided into the following main sections:

- Definitions
- Responsibility of Compounding Personnel
- CSP Microbial Contamination Risk Levels
- Personnel Training and Evaluation in Aseptic Manipulation Skills

- Immediate-Use CSPs
- Single-Dose and Multiple-Dose Containers
  - Hazardous Drugs as CSPs
  - Radiopharmaceuticals as CSPs
  - Allergen Extracts as CSPs
- Verification of Compounding Accuracy and Sterility
  - Environmental Quality and Control
- Suggested Standard Operating Procedures (SOPs)
  - Elements of Quality Control
- Verification of Automated Compounding Devices (ACDs) for Parenteral Nutrition Compounding
  - Finished Preparation Release Checks and Tests
  - Storage and Beyond-Use Dating
- Maintaining Sterility, Purity, and Stability of Dispensed and Distributed CSPs
  - Patient or Caregiver Training
- Patient Monitoring and Adverse Events Reporting
  - Quality Assurance (QA) Program
  - Abbreviations and Acronyms
  - Appendices I–V

The requirements and recommendations in this chapter are summarized in Appendix I. A list of abbreviations and acronyms is included at the end of the main text, before the Appendices.

All personnel who prepare CSPs shall be responsible for understanding these fundamental practices and precautions, for developing and implementing appropriate procedures, and for continually evaluating these procedures and the quality of final CSPs to prevent harm.

#### DEFINITIONS

**Ante-Area**— An ISO Class 8 (see [Table 1](#)) or better area where personnel hand hygiene and garbing procedures, staging of components, order entry, CSP labeling, and other high-particulate-generating activities are performed. It is also a transition area that (1) provides assurance that pressure relationships are constantly maintained so that air flows from clean to dirty areas and (2) reduces the need for the heating, ventilating, and air-conditioning (HVAC) control system to respond to large disturbances.<sup>1</sup>

**Aseptic Processing** (see [Microbiological Evaluation of Clean Rooms and Other Controlled Environments](#) [\(1116\)](#))—A mode of processing pharmaceutical and medical products that involves the separate sterilization of the product and of the package (containers—closures or packaging material for medical devices) and the transfer of the product into the container and its closure under at least ISO Class 5 (see [Table 1](#)) conditions.

**Beyond-Use Date (BUD)** (see General Notices and Requirements and [Pharmaceutical Compounding—Nonsterile Preparations](#) [\(795\)](#))—For the purpose of this chapter, the date or time after which a CSP shall not be stored or transported. The date is determined from the date or time the preparation is compounded.

**Biological Safety Cabinet (BSC)**— A ventilated cabinet for CSPs, personnel, product, and environmental protection having an open front with inward airflow for personnel protection, downward high-efficiency particulate air (HEPA)-filtered laminar airflow for product protection, and HEPA-filtered exhausted air for environmental protection.

**Buffer Area**— An area where the primary engineering control (PEC) is physically located. Activities that occur in this area include the preparation and staging of components and supplies used when compounding CSPs.

**Clean Room** (see [Microbiological Evaluation of Clean Rooms and Other Controlled Environments](#) [\(1116\)](#) and also the definition of Buffer Area)—A room in which the concentration of airborne particles is controlled to meet a specified airborne particulate cleanliness class. Microorganisms in the environment are monitored so that a microbial level for air, surface, and personnel gear are not exceeded for a specified cleanliness class.

**Compounding Aseptic Containment Isolator (CACI)**— A compounding aseptic isolator (CAI) designed to provide worker protection from exposure to undesirable levels of airborne drug throughout the compounding and material transfer processes and to provide an aseptic environment for compounding sterile preparations. Air exchange with the surrounding environment should not occur unless the air is first passed through a microbial retentive filter (HEPA minimum) system capable of containing airborne concentrations of the physical size and state of the drug being compounded. Where volatile hazardous drugs are prepared, the exhaust air from the isolator should be appropriately removed by properly designed building ventilation.

**Compounding Aseptic Isolator (CAI)**— A form of isolator specifically designed for compounding pharmaceutical ingredients or preparations. It is designed to maintain an aseptic compounding environment within the isolator throughout the compounding and material transfer processes. Air exchange into the isolator from the surrounding environment should not occur unless the air has first passed through a microbially retentive filter (HEPA minimum).<sup>2</sup>

**Critical Area**— An ISO Class 5 (see [Table 1](#)) environment.

**Critical Site**— A location that includes any component or fluid pathway surfaces (e.g., vial septa, injection ports, beakers) or openings (e.g., opened ampuls, needle hubs) exposed and at risk of direct contact with air (e.g., ambient room or HEPA filtered), moisture (e.g., oral and mucosal secretions), or touch contamination. Risk of microbial particulate contamination of the critical site increases with the size of the openings and exposure time.

**Direct Compounding Area (DCA)**— A critical area within the ISO Class 5 (see [Table 1](#)) primary engineering control (PEC) where critical sites are exposed to unidirectional HEPA-filtered air, also known as first air.

**Disinfectant**— An agent that frees from infection, usually a chemical agent but sometimes a physical one, and that destroys disease-causing pathogens or other harmful microorganisms but may not kill bacterial and fungal spores. It refers to substances applied to inanimate objects.

**First Air**— The air exiting the HEPA filter in a unidirectional air stream that is essentially particle free.

**Hazardous Drugs**— Drugs are classified as hazardous if studies in animals or humans indicate that exposures to them have a potential for causing cancer, development or reproductive toxicity, or harm to organs. (See current NIOSH publication.)

**Labeling** [see General Notices and Requirements and 21 USC 321 (k) and (m)]—A term that designates all labels and other written, printed, or graphic matter on an immediate container of an article or preparation or on, or in, any package or wrapper in which it is enclosed, except any outer shipping container. The term “label” designates that part of the labeling on the immediate container.

**Media-Fill Test** (see [Microbiological Evaluation of Clean Rooms and Other Controlled Environments](#) [\(1116\)](#))—A test used to qualify aseptic technique of compounding personnel or processes and to ensure that the processes used are able to produce sterile product without microbial contamination. During this test, a microbiological growth medium such as Soybean–Casein Digest Medium is substituted for the actual drug product to simulate admixture compounding.<sup>3</sup> The issues to consider in the development of a media-fill test are media-fill procedures, media selection, fill volume, incubation, time and temperature, inspection of filled units, documentation, interpretation of results, and possible corrective actions required.

**Multiple-Dose Container** (see General Notices and Requirements and Containers for Injections under [Injections](#) [\(1\)](#))—A multiple-unit container for articles or preparations intended for parenteral administration only and usually containing antimicrobial preservatives. The beyond-use date (BUD) for an opened or entered (e.g., needle-punctured) multiple-dose container with antimicrobial preservatives is 28 days (see [Antimicrobial Effectiveness Testing](#) [\(51\)](#)), unless otherwise specified by the manufacturer.

**Negative Pressure Room**— A room that is at a lower pressure than the adjacent spaces and, therefore, the net flow of air is into the room.<sup>1</sup>

Pharmacy Bulk Package (see Containers for Injections under [Injections \(1\)](#))—A container of a sterile preparation for parenteral use that contains many single doses. The contents are intended for use in a pharmacy admixture program and are restricted to the preparation of admixtures for infusion or, through a sterile transfer device, for the filling of empty sterile syringes. The closure shall be penetrated only one time after constitution with a suitable sterile transfer device or dispensing set, which allows measured dispensing of the contents.

The pharmacy bulk package is to be used only in a suitable work area such as a laminar flow hood (or an equivalent clean air compounding area).

Where a container is offered as a pharmacy bulk package, the label shall (a) state prominently "Pharmacy Bulk Package—Not for Direct Infusion," (b) contain or refer to information on proper techniques to help ensure safe use of the product, and (c) bear a statement limiting the time frame in which the container may be used once it has been entered, provided it is held under the labeled storage conditions.

Primary Engineering Control (PEC)—A device or room that provides an ISO Class 5 (see [Table 1](#)) environment for the exposure of critical sites when compounding CSPs. Such devices include, but may not be limited to, laminar airflow workbenches (LAFWs), biological safety cabinets (BSCs), compounding aseptic isolators (CAIs), and compounding aseptic containment isolators (CACIs).

Preparation—A preparation, or a CSP, that is a sterile drug or nutrient compounded in a licensed pharmacy or other healthcare-related facility pursuant to the order of a licensed prescriber; the article may or may not contain sterile products.

Product—A commercially manufactured sterile drug or nutrient that has been evaluated for safety and efficacy by the FDA. Products are accompanied by full prescribing information, which is commonly known as the FDA-approved manufacturer's labeling or product package insert.

Positive Pressure Room—A room that is at a higher pressure than the adjacent spaces and, therefore, the net airflow is out of the room.<sup>1</sup>

Single-Dose Container (see General Notices and Requirements and Containers for Injections under [Injections \(1\)](#))—A single-dose container is a single-unit container for articles (see General Notices and Requirements) or preparations intended for parenteral administration only. It is intended for a single use. A single-dose container is labeled as such. Examples of single-dose containers include prefilled syringes, cartridges, fusion-sealed containers, and closure-sealed containers when so labeled.

Segregated Compounding Area—A designated space, either a demarcated area or room, that is restricted to preparing low-risk level CSPs with 12-hour or less BUD. Such area shall contain a device that provides unidirectional airflow of ISO Class 5 (see [Table 1](#)) air quality for preparation of CSPs and shall be void of activities and materials that are extraneous to sterile compounding.

Sterilizing Grade Membranes—Membranes that are documented to retain 100% of a culture of 107 microorganisms of a strain of *Brevundimonas (Pseudomonas) diminuta* per square centimeter of membrane surface under a pressure of not less than 30 psi (2.0 bar). Such filter membranes are nominally at 0.22-μm or 0.2-μm nominal pore size, depending on the manufacturer's practice.

Sterilization by Filtration—Passage of a fluid or solution through a sterilizing grade membrane to produce a sterile effluent.

Terminal Sterilization—The application of a lethal process (e.g., steam under pressure or autoclaving) to sealed containers for the purpose of achieving a predetermined sterility assurance level of usually less than 10<sup>-6</sup>, or a probability of less than one in one million of a nonsterile unit.<sup>3</sup>

Unidirectional Flow (see footnote 3)—An airflow moving in a single direction in a robust and uniform manner and at sufficient speed to reproducibly sweep particles away from the critical processing or testing area.

#### RESPONSIBILITY OF COMPOUNDING PERSONNEL

Compounding personnel are responsible for ensuring that CSPs are accurately identified, measured, diluted, and mixed and are correctly purified, sterilized, packaged, sealed, labeled, stored, dispensed, and distributed. These performance responsibilities include maintaining appropriate cleanliness conditions and providing labeling and supplementary instructions for the proper clinical administration of CSPs.

Compounding supervisors shall ensure, through either direct measurement or appropriate information sources, that specific CSPs maintain their labeled strength within monograph limits for USP articles, or within 10% if not specified, until their BUDs. All CSPs are prepared in a manner that maintains sterility and minimizes the introduction of particulate matter.

A written quality assurance procedure includes the following in-process checks that are applied, as appropriate, to specific CSPs: accuracy and precision of measuring and weighing; the requirement for sterility; methods of sterilization and purification; safe limits and ranges for strength of ingredients, bacterial endotoxins, and particulate matter; pH; labeling accuracy and completeness; BUD assignment; and packaging and storage requirements. The dispenser shall, when appropriate and practicable, obtain and evaluate results of testing for identity, strength, purity, and sterility before a CSP is dispensed. Qualified licensed healthcare professionals who supervise compounding and dispensing of CSPs shall ensure that the following objectives are achieved:

1. Compounding personnel are adequately skilled, educated, instructed, and trained to correctly perform and document the following activities in their sterile compounding duties:
  - a. perform antiseptic hand cleansing and disinfection of nonsterile compounding surfaces;
  - b. select and appropriately don protective garb;
  - c. maintain or achieve sterility of CSPs in ISO Class 5 (see [Table 1](#)) PEC devices and protect personnel and compounding environments from contamination by radioactive, cytotoxic, and chemotoxic drugs (see Hazardous Drugs as CSPs and Radiopharmaceuticals as CSPs);
  - d. identify, weigh, and measure ingredients; and
  - e. manipulate sterile products aseptically, sterilize high-risk level CSPs, and label and quality inspect CSPs.
2. Ingredients have their correct identity, quality, and purity.
3. Opened or partially used packages of ingredients for subsequent use in CSPs are properly stored under restricted access conditions in the compounding facility. Such packages cannot be used when visual inspection detects unauthorized breaks in the container, closure, and seal; when the contents do not possess the expected appearance, aroma, and texture; when the contents do not pass identification tests specified by the compounding facility; and when either the BUD or expiration date has been exceeded.
4. Water-containing CSPs that are nonsterile during any phase of the compounding procedure are sterilized within 6 hours after completing the preparation in order to minimize the generation of bacterial endotoxins.
5. Sterilization methods achieve sterility of CSPs while maintaining the labeled strength of active ingredients and the physical integrity of packaging.
6. Measuring, mixing, sterilizing, and purifying devices are clean, appropriately accurate, and effective for their intended use.
7. Potential harm from added substances and differences in rate and extent of bioavailability of active ingredients for other than oral route of administration are carefully evaluated before such CSPs are dispensed and administered.
  8. Packaging selected for CSPs is appropriate to preserve the sterility and strength until the BUD.
9. While being used, the compounding environment maintains the sterility or the presterilization purity, whichever is appropriate, of the CSP.
10. Labels on CSPs list the names and amounts or concentrations of active ingredients, and the labels or labeling of injections (see Preservation, Packaging, Storage, and Labeling in the General Notices and Requirements) list the names and amounts or concentrations of all ingredients (see [Injections \(1\)](#)). Before being dispensed or administered, the clarity of solutions is visually confirmed; also, the identity and amounts of ingredients, procedures to prepare and sterilize CSPs, and specific release criteria are reviewed to ensure their accuracy and completeness.
11. BUDs are assigned on the basis of direct testing or extrapolation from reliable literature sources and other documentation (see Stability Criteria and Beyond-Use Dating under [Pharmaceutical Compounding—Nonsterile Preparations \(795\)](#)).
12. Procedures for measuring, mixing, dilution, purification, sterilization, packaging, and labeling conform to the correct sequence and quality established for the specified CSP.
  13. Deficiencies in compounding, labeling, packaging, and quality testing and inspection can be rapidly identified and corrected.
14. When time and personnel availability so permit, compounding manipulations and procedures are separated from postcompounding quality inspection and review before CSPs are dispensed.

This chapter emphasizes the need to maintain high standards for the quality and control of processes, components, and environments and for the skill and knowledge of personnel

who prepare CSPs. The rigor of in-process quality-control checks and of postcompounding quality inspection and testing increases with the potential hazard of the route of administration. For example, nonsterility, excessive bacterial endotoxin contamination, large errors in strength of correct ingredients, and incorrect ingredients in CSPs are potentially more dangerous to patients when the CSPs are administered into the vascular and central nervous systems than when administered by most other routes.

#### CSP MICROBIAL CONTAMINATION RISK LEVELS

The three contamination categories for CSPs described in this section are assigned primarily according to the potential for microbial contamination during the compounding of low-risk level CSPs and medium-risk level CSPs or the potential for not sterilizing high-risk level CSPs, any of which would subject patients to risk of harm, including death. High-risk level

CSPs must be sterilized before being administered to patients. The appropriate risk level—low, medium, or high—is assigned according to the corresponding probability of contaminating a CSP with (1) microbial contamination (e.g., microbial organisms, spores, endotoxins) and (2) chemical and physical contamination (e.g., foreign chemicals, physical matter). Potential sources of contamination include, but are not limited to, solid and liquid matter from compounding personnel and objects; nonsterile components employed and incorporated before terminal sterilization; inappropriate conditions within the restricted compounding environment; prolonged presterilization procedures with aqueous preparations; and nonsterile dosage forms used to compound CSPs.

The characteristics described below for low-, medium-, and high-risk level CSPs are intended as a guide to the breadth and depth of care necessary in compounding, but they are neither exhaustive nor prescriptive. The licensed healthcare professionals who supervise compounding are responsible for determining the procedural and environmental quality practices and attributes that are necessary for the risk level they assign to specific CSPs.

These risk levels apply to the quality of CSPs immediately after the final aseptic mixing or filling or immediately after the final sterilization, unless precluded by the specific characteristics of the preparation. Upon subsequent storage and shipping of freshly finished CSPs, an increase in the risks of chemical degradation of ingredients, contamination from physical damage to packaging, and permeability of plastic and elastomeric packaging is expected. In such cases, compounding personnel are responsible for considering the potential additional risks to the integrity of CSPs when assigning BUDs. The pre-administration storage duration and temperature limits specified in the following subsections apply in the absence of direct sterility testing results that justify different limits for specific CSPs.

##### Low-Risk Level CSPs

CSPs compounded under all the following conditions are at a low risk of contamination.

##### Low-Risk Conditions—

1. The CSPs are compounded with aseptic manipulations entirely within ISO Class 5 (see [Table 1](#)) or better air quality using only sterile ingredients, products, components, and devices.
2. The compounding involves only transfer, measuring, and mixing manipulations using not more than three commercially manufactured packages of sterile products and not more than two entries into any one sterile container or package (e.g., bag, vial) of sterile product or administration container/device to prepare the CSP.
3. Manipulations are limited to aseptically opening ampuls, penetrating disinfected stoppers on vials with sterile needles and syringes, and transferring sterile liquids in sterile syringes to sterile administration devices, package containers of other sterile products, and containers for storage and dispensing.
4. For a low-risk level preparation, in the absence of passing a sterility test (see [Sterility Tests \(71\)](#)), the storage periods cannot exceed the following time periods: before administration, the CSPs are properly stored and are exposed for not more than 48 hours at controlled room temperature (see General Notices and Requirements), for not more than 14 days at a cold temperature (see General Notices and Requirements), and for 45 days in solid frozen state between  $-25^{\circ}$  and  $-10^{\circ}$ .

##### Examples of Low-Risk Compounding—

1. Single-volume transfers of sterile dosage forms from ampuls, bottles, bags, and vials using sterile syringes with sterile needles, other administration devices, and other sterile containers. The solution content of ampuls should be passed through a sterile filter to remove any particles.
2. Simple aseptic measuring and transferring with not more than three packages of manufactured sterile products, including an infusion or diluent solution to compound drug admixtures and nutritional solutions.

**Low-Risk Level CSPs with 12-Hour or Less BUD**— If the PEC is a CAI or CACI that does not meet the requirements described in Placement of Primary Engineering Controls or is a laminar airflow workbench (LAFW) or a biological safety cabinet (BSC) that cannot be located within an ISO Class 7 (see [Table 1](#)) buffer area, then only low-risk level nonhazardous and radiopharmaceutical CSPs pursuant to a physician's order for a specific patient may be prepared, and administration of such CSPs shall commence within 12 hours of preparation or as recommended in the manufacturers' package insert, whichever is less. Low-risk level CSPs with a 12-hour or less BUD shall meet all of the following four criteria:

1. PECs (LAFWs, BSCs, CAIs, CACIs,) shall be certified and maintain ISO Class 5 (see [Table 1](#)) as described in Facility Design and Environmental Controls for exposure of critical sites and shall be in a segregated compounding area restricted to sterile compounding activities that minimize the risk of CSP contamination.
2. The segregated compounding area shall not be in a location that has unsealed windows or doors that connect to the outdoors or high traffic flow, or that is adjacent to construction sites, warehouses, or food preparation. Note that this list is not intended to be all inclusive.
3. Personnel shall follow the procedures described in Personnel Cleansing and Garbing and Additional Personnel Requirements prior to compounding. Sinks should not be located adjacent to the ISO Class 5 (see [Table 1](#)) PEC. Sinks should be separated from the immediate area of the ISO Class 5 (see [Table 1](#)) PEC device.
4. The specifications in Cleaning and Disinfecting the Sterile Compounding Areas, Personnel Training and Competency Evaluation of Garbing, Aseptic Work Practices and Cleaning/Disinfection Procedures, and Viable and Nonviable Environmental Sampling (ES) Testing shall be followed as described in the chapter.

Compounding personnel must recognize that the absence of an ISO Class 7 (see [Table 1](#)) buffer area environment in a general uncontrolled environment increases the potential of microbial contamination, and administration durations of microbially contaminated CSPs exceeding a few hours increase the potential for clinically significant microbial colonization, and thus for patient harm, especially in critically ill or immunocompromised patients.

##### Quality Assurance— Quality assurance practices include, but are not limited to the following:

1. Routine disinfection and air quality testing of the direct compounding environment to minimize microbial surface contamination and maintain ISO Class 5 (see [Table 1](#)) air quality.
2. Visual confirmation that compounding personnel are properly donning and wearing appropriate items and types of protective garments, including eye protection and face masks.
3. Review of all orders and packages of ingredients to ensure that the correct identity and amounts of ingredients were compounded.
4. Visual inspection of CSPs to ensure the absence of particulate matter in solutions, the absence of leakage from vials and bags, and the accuracy and thoroughness of labeling.

**Media-Fill Test Procedure**— This test or an equivalent test is performed at least annually by each person authorized to compound in a low-risk level environment under conditions that closely simulate the most challenging or stressful conditions encountered during compounding of low-risk level CSPs. Once begun, this test is completed without interruption. Example of test procedure: within an ISO Class 5 (see [Table 1](#)) air quality environment, three sets of four 5-mL aliquots of sterile Soybean–Casein Digest Medium (also known as trypticase soy broth or trypticase soy agar [TSA]) are transferred with the same sterile 10-mL syringe and vented needle combination into separate sealed, empty, sterile 30-mL clear vials (i.e., four 5-mL aliquots into each of three 30-mL vials). Sterile adhesive seals are aseptically affixed to the rubber closures on the three filled vials, then the vials are incubated at  $20^{\circ}$  to  $25^{\circ}$  or at  $30^{\circ}$  to  $35^{\circ}$  for a minimum of 14 days. If two temperatures are used for incubation of media-filled samples, then these filled containers should be incubated for at least 7 days at each temperature (see [Microbiological Evaluation of Clean Rooms and Other Controlled Environments \(116\)](#)). Inspect for microbial growth over 14 days as described in Personnel Training and Competency Evaluation of Garbing, Aseptic Work Practices and Cleaning/Disinfection Procedures.

## Medium-Risk Level CSPs

When CSPs are compounded aseptically under Low-Risk Conditions and one or more of the following conditions exists, such CSPs are at a medium risk of contamination.

## Medium-Risk Conditions—

1. Multiple individual or small doses of sterile products are combined or pooled to prepare a CSP that will be administered either to multiple patients or to one patient on multiple occasions.
2. The compounding process includes complex aseptic manipulations other than the single-volume transfer.
3. The compounding process requires unusually long duration, such as that required to complete dissolution or homogeneous mixing.
4. For a medium-risk preparation, in the absence of passing a sterility test (see [Sterility Tests \(71\)](#)), the storage periods cannot exceed the following time periods: before administration, the CSPs are properly stored and are exposed for not more than 30 hours at controlled room temperature (see General Notices and Requirements), for not more than 9 days at a cold temperature (see General Notices and Requirements), and for 45 days in solid frozen state between  $-25^{\circ}$  and  $-10^{\circ}$ .

## Examples of Medium-Risk Compounding—

1. Compounding of total parenteral nutrition fluids using manual or automated devices during which there are multiple injections, detachments, and attachments of nutrient source products to the device or machine to deliver all nutritional components to a final sterile container.
2. Filling of reservoirs of injection and infusion devices with more than three sterile drug products and evacuation of air from those reservoirs before the filled device is dispensed.
3. Transfer of volumes from multiple ampuls or vials into one or more final sterile containers.

Quality Assurance— Quality assurance procedures for medium-risk level CSPs include all those for low-risk level CSPs, as well as a more challenging media-fill test passed annually or more frequently.

Media-Fill Test Procedure— This test or an equivalent test is performed at least annually under conditions that closely simulate the most challenging or stressful conditions encountered during compounding. Once begun, this test is completed without interruption. Example of test procedure: within an ISO Class 5 (see [Table 1](#)) air quality environment, six 100-mL aliquots of sterile Soybean–Casein Digest Medium are aseptically transferred by gravity through separate tubing sets into separate evacuated sterile containers. The six containers are then arranged as three pairs, and a sterile 10-mL syringe and 18-gauge needle combination is used to exchange two 5-mL aliquots of medium from one container to the other container in the pair. For example, after a 5-mL aliquot from the first container is added to the second container in the pair, the second container is agitated for 10 seconds, then a 5-mL aliquot is removed and returned to the first container in the pair. The first container is then agitated for 10 seconds, and the next 5-mL aliquot is transferred from it back to the second container in the pair. Following the two 5-mL aliquot exchanges in each pair of containers, a 5-mL aliquot of medium from each container is aseptically injected into a sealed, empty, sterile 10-mL clear vial, using a sterile 10-mL syringe and vented needle. Sterile adhesive seals are aseptically affixed to the rubber closures on the three filled vials, then the vials are incubated at  $20^{\circ}$  to  $25^{\circ}$  or at  $30^{\circ}$  to  $35^{\circ}$  for a minimum of 14 days. If two temperatures are used for incubation of media-filled samples, then these filled containers should be incubated for at least 7 days at each temperature (see [Microbiological Evaluation of Clean Rooms and Other Controlled Environments \(116\)](#)). Inspect for microbial growth over 14 days as described in Personnel Training and Competency Evaluation of Garbing, Aseptic Work Practices and Cleaning/Disinfection Procedures.

## High-Risk Level CSPs

CSPs compounded under any of the following conditions are either contaminated or at a high risk to become contaminated.

## High-Risk Conditions—

1. Nonsterile ingredients, including manufactured products not intended for sterile routes of administration (e.g., oral), are incorporated or a nonsterile device is employed before terminal sterilization.
2. Any of the following are exposed to air quality worse than ISO Class 5 (see [Table 1](#)) for more than 1 hour (see Immediate-Use CSPs):
  - sterile contents of commercially manufactured products,
  - CSPs that lack effective antimicrobial preservatives, and
  - sterile surfaces of devices and containers for the preparation, transfer, sterilization, and packaging of CSPs.
3. Compounding personnel are improperly garbed and gloved (see Personnel Cleansing and Use of Barrier Protective Equipment).
4. Nonsterile water-containing preparations are stored for more than 6 hours before being sterilized.
5. It is assumed, and not verified by examination of labeling and documentation from suppliers or by direct determination, that the chemical purity and content strength of ingredients meet their original or compendial specifications in unopened or in opened packages of bulk ingredients (see Ingredient Selection under [Pharmaceutical Compounding—Nonsterile Preparations \(795\)](#)).

For a sterilized high-risk level preparation, in the absence of passing a sterility test, the storage periods cannot exceed the following time periods: before administration, the CSPs are properly stored and are exposed for not more than 24 hours at controlled room temperature (see General Notices and Requirements), for not more than 3 days at a cold temperature (see General Notices and Requirements), and for 45 days in solid frozen state between  $-25^{\circ}$  and  $-10^{\circ}$ . [note—Sterility tests for autoclaved CSPs are not required unless they are prepared in batches of more than 25 units.]

All nonsterile measuring, mixing, and purifying devices are rinsed thoroughly with sterile, pyrogen-free water, and then thoroughly drained or dried immediately before use for high-risk compounding. All high-risk level CSP solutions subjected to terminal sterilization are prefilled by passing through a filter with a nominal pore size not larger than 1.2  $\mu\text{m}$  preceding or during filling into their final containers to remove particulate matter. Sterilization of high-risk level CSPs by filtration shall be performed with a sterile 0.2- $\mu\text{m}$  or 0.22- $\mu\text{m}$  nominal pore size filter entirely within an ISO Class 5 (see [Table 1](#)) or superior air quality environment.

## Examples of High-Risk Conditions—

1. Dissolving nonsterile bulk drug and nutrient powders to make solutions that will be terminally sterilized.
2. Exposing the sterile ingredients and components used to prepare and package CSPs to room air quality worse than ISO Class 5 (see [Table 1](#)) for more than 1 hour (see Immediate-Use CSPs).
3. Measuring and mixing sterile ingredients in nonsterile devices before sterilization is performed.
4. Assuming, without appropriate evidence or direct determination, that packages of bulk ingredients contain at least 95% by weight of their active chemical moiety and have not been contaminated or adulterated between uses.

Quality Assurance— Quality assurance procedures for high-risk level CSPs include all those for low-risk level CSPs. In addition, a media-fill test that represents high-risk level compounding is performed semiannually by each person authorized to compound high-risk level CSPs.

Media-Fill Test Procedure for CSPs Sterilized by Filtration— This test or an equivalent test is performed under conditions that closely simulate the most challenging or stressful conditions encountered when compounding high-risk level CSPs. Once begun, this test is completed without interruption. Example of test procedure (in the following sequence):

1. Dissolve 3 g of nonsterile commercially available Soybean–Casein Digest Medium in 100 mL of nonbacteriostatic water to make a 3% nonsterile solution.
2. Draw 25 mL of the medium into each of three 30-mL sterile syringes. Transfer 5 mL from each syringe into separate sterile 10-mL vials. These vials are the positive controls to generate exponential microbial growth, which is indicated by visible turbidity upon incubation.
3. Under aseptic conditions and using aseptic techniques, affix a sterile 0.2- $\mu\text{m}$  or 0.22- $\mu\text{m}$  nominal pore size filter unit and a 20-gauge needle to each syringe. Inject the next 10 mL from each syringe into three separate 10-mL sterile vials. Repeat the process for three more vials. Label all vials, affix sterile adhesive seals to the closure of the nine vials, and incubate them at  $20^{\circ}$  to  $25^{\circ}$  or at  $30^{\circ}$  to  $35^{\circ}$  for a minimum of 14 days. If two temperatures are used for incubation of media-filled samples, then these filled containers

should be incubated for at least 7 days at each temperature (see [Microbiological Evaluation of Clean Rooms and Other Controlled Environments](#) (116)). Inspect for microbial growth over 14 days as described in Personnel Training and Competency Evaluation of Garbing, Aseptic Work Practices and Cleaning/Disinfection Procedures.

#### PERSONNEL TRAINING AND EVALUATION IN ASEPTIC MANIPULATION SKILLS

Personnel who prepare CSPs shall be trained conscientiously and skillfully by expert personnel and through audio-video instructional sources and professional publications in the theoretical principles and practical skills of aseptic manipulations and in achieving and maintaining ISO Class 5 (see [Table 1](#)) environmental conditions before they begin to prepare CSPs. Compounding personnel shall perform didactic review and pass written and media-fill testing of aseptic manipulative skills initially, at least annually thereafter for low- and medium-risk level compounding, and semiannually for high-risk level compounding. Compounding personnel who fail written tests or whose media-fill test vials result in gross microbial colonization shall be immediately re-instructed and re-evaluated by expert compounding personnel to ensure correction of all aseptic practice deficiencies.

**Media-Fill Challenge Testing**— The skill of personnel to aseptically prepare CSPs may be evaluated using sterile fluid bacterial culture media-fill verification<sup>3</sup> (i.e., sterile bacterial culture medium transfer via a sterile syringe and needle). Media-fill testing is used to assess the quality of the aseptic skill of compounding personnel. Media-fill tests represent the most challenging or stressful conditions actually encountered by the personnel being evaluated when they prepare particular risk level CSPs and when sterilizing high-risk level CSPs. Media-fill challenge tests that simulate high-risk level compounding are also used to verify the capability of the compounding environment and process to produce a sterile preparation.

Commercially available sterile fluid culture media, such as Soybean–Casein Digest Medium (see [Sterility Tests](#) (71)), shall be able to promote exponential colonization of bacteria that are most likely to be transmitted to CSPs from the compounding personnel and environment. Media-filled vials are generally incubated at 20° to 25° or at 30° to 35° for a minimum of 14 days. If two temperatures are used for incubation of media-filled samples, then these filled containers should be incubated for at least 7 days at each temperature (see [Microbiological Evaluation of Clean Rooms and Other Controlled Environments](#) (116)). Failure is indicated by visible turbidity in the medium on or before 14 days.

#### IMMEDIATE-USE CSPS

The immediate-use provision is intended only for those situations where there is a need for emergency or immediate patient administration of a CSP. Such situations may include cardiopulmonary resuscitation, emergency room treatment, preparation of diagnostic agents, or critical therapy where the preparation of the CSP under conditions described for Low-Risk Level CSPs subjects the patient to additional risk due to delays in therapy. Immediate-use CSPs are not intended for storage for anticipated needs or batch compounding.

Preparations that are medium-risk level and high-risk level CSPs shall not be prepared as immediate-use CSPs.

Immediate-use CSPs are exempt from the requirements described for Low-Risk Level CSPs only when all of the following criteria are met:

1. The compounding process involves simple transfer of not more than three commercially manufactured packages of sterile nonhazardous products or diagnostic radiopharmaceutical products from the manufacturers' original containers and not more than two entries into any one container or package (e.g., bag, vial) of sterile infusion solution or administration container/device. For example, anti-neoplastics shall not be prepared as immediate-use CSPs because they are hazardous drugs.
2. Unless required for the preparation, the compounding procedure is a continuous process not to exceed 1 hour.
3. During preparation, aseptic technique is followed and, if not immediately administered, the finished CSP is under continuous supervision to minimize the potential for contact with nonsterile surfaces, introduction of particulate matter or biological fluids, mix-ups with other CSPs, and direct contact of outside surfaces.
4. Administration begins not later than 1 hour following the start of the preparation of the CSP.
5. Unless immediately and completely administered by the person who prepared it or immediate and complete administration is witnessed by the preparer, the CSP shall bear a label listing patient identification information, the names and amounts of all ingredients, the name or initials of the person who prepared the CSP, and the exact 1-hour BUD and time.
6. If administration has not begun within 1 hour following the start of preparing the CSP, the CSP shall be promptly, properly, and safely discarded.

Compounding in worse than ISO Class 5 (see [Table 1](#)) conditions increases the likelihood of microbial contamination, and administration durations of microbially contaminated CSPs exceeding a few hours increase the potential for clinically significant microbial colonization and thus for patient harm, especially in critically ill or immunocompromised patients.

#### SINGLE-DOSE AND MULTIPLE-DOSE CONTAINERS

Opened or needle-punctured single-dose containers, such as bags, bottles, syringes, and vials of sterile products and CSPs shall be used within 1 hour if opened in worse than ISO Class 5 (see [Table 1](#)) air quality (see [Immediate-Use CSPs](#)), and any remaining contents must be discarded. Single-dose vials exposed to ISO Class 5 (see [Table 1](#)) or cleaner air may be used up to 6 hours after initial needle puncture. Opened single-dose ampuls shall not be stored for any time period. Multiple-dose containers (e.g., vials) are formulated for removal of portions on multiple occasions because they usually contain antimicrobial preservatives. The BUD after initially entering or opening (e.g., needle-punctured) multiple-dose containers is 28 days (see [Antimicrobial Effectiveness Testing](#) (51)) unless otherwise specified by the manufacturer.

#### HAZARDOUS DRUGS AS CSPS

Although the potential therapeutic benefits of compounded sterile hazardous drug preparations generally outweigh the risks of their adverse effects in ill patients, exposed healthcare workers risk similar adverse effects with no therapeutic benefit. Occupational exposure to hazardous drugs can result in (1) acute effects, such as skin rashes; (2) chronic effects, including adverse reproductive events; and (3) possibly cancer (see Appendix A of NIOSH Publication no. 2004-165).

Hazardous drugs shall be prepared for administration only under conditions that protect the healthcare workers and other personnel in the preparation and storage areas. Hazardous drugs shall be stored separately from other inventory in a manner to prevent contamination and personnel exposure. Many hazardous drugs have sufficient vapor pressures that allow volatilization at room temperature; thus storage is preferably within a containment area such as a negative pressure room. The storage area should have sufficient general exhaust ventilation, at least 12 air changes per hour (ACPH)<sup>4</sup> to dilute and remove any airborne contaminants.

Hazardous drugs shall be handled with caution at all times using appropriate chemotherapy gloves during receiving, distribution, stocking, inventorying, preparation for administration, and disposal. Hazardous drugs shall be prepared in an ISO Class 5 (see [Table 1](#)) environment with protective engineering controls in place and following aseptic practices specified for the appropriate contamination risk levels defined in this chapter. Access shall be limited to areas where drugs are stored and prepared to protect persons not involved in drug preparation.

All hazardous drugs shall be prepared in a BSC<sup>5</sup> or a CACI that meets or exceeds the standards for CACI in this chapter. The ISO Class 5 (see [Table 1](#)) BSC or CACI shall be placed in an ISO Class 7 (see [Table 1](#)) area that is physically separated (i.e., a different area from other preparation areas) and optimally has not less than 0.01-inch water column negative pressure to adjacent positive pressure ISO Class 7 (see [Table 1](#)) or better ante-areas, thus providing inward airflow to contain any airborne drug. A pressure indicator shall be installed that can be readily monitored for correct room pressurization. The BSC and CACI optimally should be 100% vented to the outside air through HEPA filtration.

If a CACI that meets the requirements of this chapter is used outside of a buffer area, the compounding area shall maintain a minimum negative pressure of 0.01-inch water column and have a minimum of 12 ACPHs.

When closed-system vial-transfer devices (CSTDs) (i.e., vial-transfer systems that allow no venting or exposure of hazardous substance to the environment) are used, they shall be used within the ISO Class 5 (see [Table 1](#)) environment of a BSC or CACI. The use of a CSTD is preferred because of their inherent closed system process. In facilities that prepare a low volume of hazardous drugs, the use of two tiers of containment (e.g., CSTD within a BSC or CACI that is located in a non-negative pressure room) is acceptable.

Appropriate personnel protective equipment (PPE) shall be worn when compounding in a BSC or CACI and when using CSTD devices. PPE should include gowns, face masks, eye protection, hair covers, shoe covers or dedicated shoes, double gloving with sterile chemo-type gloves, and compliance with manufacturers' recommendations when using a CACI.

All personnel who compound hazardous drugs shall be fully trained in the storage, handling, and disposal of these drugs. This training shall occur prior to preparing or handling

hazardous CSPs, and its effectiveness shall be verified by testing specific hazardous drugs preparation techniques. Such verification shall be documented for each person at least annually. This training shall include didactic overview of hazardous drugs, including mutagenic, teratogenic, and carcinogenic properties, and it shall include ongoing training for each new hazardous drug that enters the marketplace. Compounding personnel of reproductive capability shall confirm in writing that they understand the risks of handling hazardous drugs.

The training shall include at least the following: (1) safe aseptic manipulation practices; (2) negative pressure techniques when utilizing a BSC or CACI; (3) correct use of CSTD devices; (4) containment, cleanup, and disposal procedures for breakages and spills; and (5) treatment of personnel contact and inhalation exposure.

note—Because standards of assay and unacceptable quantities of contamination of each drug have not been established in the literature, the following paragraph is a recommendation only. Future standards will be adopted as these assay methods are developed and proven.

In order to ensure containment, especially in operations preparing large volumes of hazardous drugs, environmental sampling to detect uncontaminated hazardous drugs should be performed routinely (e.g., initially as a benchmark and at least every 6 months or more often as needed to verify containment). This sampling should include surface wipe sampling of the working area of BSCs and CACIs; counter tops where finished preparations are placed; areas adjacent to BSCs and CACIs, including the floor directly under the working area; and patient administration areas. Common marker hazardous drugs that can be assayed include cyclophosphamide, ifosfamide, methotrexate, and fluorouracil. If any measurable contamination (cyclophosphamide levels greater than 1.00 ng per cm<sup>2</sup> have been found to cause human uptake) is found by any of these quality assurance procedures, practitioners shall make the decision to identify, document, and contain the cause of contamination. Such action may include retraining, thorough cleaning (utilizing high-pH soap and water), and improving engineering controls. Examples of improving engineering controls are (1) venting BSCs or CACIs 100% to the outside, (2) implementing a CSTD, or (3) re-assessing types of BSCs or CACIs.

Disposal of all hazardous drug wastes shall comply with all applicable federal and state regulations. All personnel who perform routine custodial waste removal and cleaning activities in storage and preparation areas for hazardous drugs shall be trained in appropriate procedures to protect themselves and prevent contamination.

#### RADIOPHARMACEUTICALS AS CSPs

In the case of production of radiopharmaceuticals for positron emission tomography (PET), general test chapter [Radiopharmaceuticals for Positron Emission Tomography—Compounding](#) (823) supersedes this chapter. Upon release of a PET radiopharmaceutical as a finished drug product from a production facility, the further handling, manipulation, or use of the product will be considered compounding, and the content of this section and chapter is applicable.

For the purposes of this chapter, radiopharmaceuticals compounded from sterile components in closed sterile containers and with a volume of 100 mL or less for a single-dose injection or not more than 30 mL taken from a multiple-dose container (see [Injections](#) (1)) shall be designated as, and conform to, the standards for Low-Risk Level CSPs.

These radiopharmaceuticals shall be compounded using appropriately shielded vials and syringes in a properly functioning and certified ISO Class 5 (see [Table 1](#)) PEC located in an ISO Class 8 (see [Table 1](#)) or cleaner air environment to permit compliance with special handling, shielding, and negative air flow requirements.

Radiopharmaceutical vials designed for multi-use, compounded with technetium-99m, exposed to ISO Class 5 (see [Table 1](#)) environment, and punctured by needles with no direct contact contamination may be used up to the time indicated by manufacturers' recommendations. Storage and transport of properly shielded vials of radiopharmaceutical CSPs may occur in a limited access ambient environment without a specific ISO class designation.

Technetium-99m/molybdenum-99 generator systems shall be stored and eluted (operated) under conditions recommended by manufacturers and applicable state and federal regulations. Such generator systems shall be eluted in an ISO Class 8 (see [Table 1](#)) or cleaner air environment to permit special handling, shielding, and air flow requirements. To limit acute and chronic radiation exposure of inspecting personnel to a level that is as low as reasonably achievable (ALARA), direct visual inspection of radiopharmaceutical CSPs containing high concentrations of doses of radioactivity shall be conducted in accordance with ALARA.

Radiopharmaceuticals prepared as Low-Risk Level CSPs with 12-Hour or Less BUD shall be prepared in a segregated compounding area. A line of demarcation defining the segregated compounding area shall be established. Materials and garb exposed in a patient care and treatment area shall not cross a line of demarcation into the segregated compounding area.

#### ALLERGEN EXTRACTS AS CSPs

Allergen extracts as CSPs are single-dose and multiple-dose intradermal or subcutaneous injections that are prepared by specially trained physicians and personnel under their direct supervision. Allergen extracts as CSPs are not subject to the personnel, environmental, and storage requirements for all CSP Microbial Contamination Risk Levels in this chapter only when all of the following criteria are met:

1. The compounding process involves simple transfer via sterile needles and syringes of commercial sterile allergen products and appropriate sterile added substances (e.g., glycerin, phenol in sodium chloride injection).
2. All allergen extracts as CSPs shall contain appropriate substances in effective concentrations to prevent the growth of microorganisms. Nonpreserved allergen extracts shall comply with the appropriate CSP risk level requirements in the chapter.
3. Before beginning compounding activities, personnel perform a thorough hand-cleansing procedure by removing debris from under fingernails using a nail cleaner under running warm water followed by vigorous hand and arm washing to the elbows for at least 30 seconds with either nonantimicrobial or antimicrobial soap and water.
  4. Compounding personnel don hair covers, facial hair covers, gowns, and face masks.
  5. Compounding personnel perform antiseptic hand cleansing with an alcohol-based surgical hand scrub with persistent activity.
  6. Compounding personnel don powder-free sterile gloves that are compatible with sterile 70% isopropyl alcohol (IPA) before beginning compounding manipulations.
  7. Compounding personnel disinfect their gloves intermittently with sterile 70% IPA when preparing multiple allergen extracts as CSPs.
8. Ampul necks and vial stoppers on packages of manufactured sterile ingredients are disinfected by careful wiping with sterile 70% IPA swabs to ensure that the critical sites are wet for at least 10 seconds and allowed to dry before they are used to compound allergen extracts as CSPs.
9. The aseptic compounding manipulations minimize direct contact contamination (e.g., from glove fingertips, blood, nasal and oral secretions, shed skin and cosmetics, other nonsterile materials) of critical sites (e.g., needles, opened ampuls, vial stoppers).
10. The label of each multiple-dose vial (MDV) of allergen extracts as CSPs lists the name of one specific patient and a BUD and storage temperature range that is assigned based on manufacturers' recommendations or peer-reviewed publications.
11. Single-dose allergen extracts as CSPs shall not be stored for subsequent additional use.

Personnel who compound allergen extracts as CSPs must be aware of greater potential risk of microbial and foreign material contamination when allergen extracts as CSPs are compounded in compliance with the foregoing criteria instead of the more rigorous standards in this chapter for CSP Microbial Contamination Risk Levels. Although contaminated allergen extracts as CSPs can pose health risks to patients when they are injected intradermally or subcutaneously, these risks are substantially greater if the extract is inadvertently injected intravenously.

#### VERIFICATION OF COMPOUNDING ACCURACY AND STERILITY

The compounding procedures and sterilization methods for CSPs correspond to correctly designed and verified written documentation in the compounding facility. Verification requires planned testing, monitoring, and documentation to demonstrate adherence to environmental quality requirements, personnel practices, and procedures critical to achieving and maintaining sterility, accuracy, and purity of finished CSPs. For example, sterility testing (see Test for Sterility of the Product To Be Examined under [Sterility Tests](#) (71)) may be applied to specimens of low- and medium-risk level CSPs, and standard self-contained biological indicators (BI) shall be added to nondispensable specimens of high-risk level CSPs before terminal sterilization for subsequent evaluation to determine whether the sterilization cycle was adequate (see [Biological Indicators for Sterilization](#) (1035)). Packaged and labeled CSPs shall be visually inspected for physical integrity and expected appearance, including final fill amount. The accuracy of identities, concentrations, amounts, and purities of ingredients in CSPs shall be confirmed by reviewing labels on packages, observing and documenting correct measurements with approved and correctly standardized devices, and reviewing information in labeling and certificates of analysis provided by suppliers. When the correct identity, purity, strength, and sterility of ingredients and components of CSPs

cannot be confirmed (in cases of, for example, unlabeled syringes, opened ampuls, punctured stoppers of vials and bags, containers of ingredients with incomplete labeling), such ingredients and components shall be discarded immediately.

Some individual ingredients, such as bulk drug substances, are not labeled with expiration dates when they are stable indefinitely in their commercial packages under their labeled storage conditions. However, despite retaining full chemical stability, such ingredients may gain or lose moisture during storage and use. Changes in moisture content may require testing (see [Loss on Drying \(731\)](#)) to determine the correct amount to weigh for accurate content of active chemical moieties in CSPs (see [Pharmaceutical Calculations in Prescription Compounding \(1160\)](#)).

Although not required, a quantitative stability-indicating chemical assay is recommended to ensure compounding accuracy of CSPs, especially those that contain drug ingredients with a narrow therapeutic plasma concentration range.

#### Sterilization Methods

The licensed healthcare professionals who supervise compounding shall be responsible for determining that the selected sterilization method (see [Methods of Sterilization under Sterilization and Sterility Assurance of Compendial Articles \(1211\)](#)) both sterilizes and maintains the strength, purity, quality, and packaging integrity of CSPs. The selected sterilization process is obtained from experience and appropriate information sources (e.g., see [Sterilization and Sterility Assurance of Compendial Articles \(1211\)](#))—and, preferably, verified wherever possible—to achieve sterility in the particular CSPs. General guidelines for matching CSPs and components to appropriate sterilization methods include the following:

1. CSPs have been ascertained to remain physically and chemically stable when subjected to the selected sterilization method.
2. Glass and metal devices may be covered tightly with aluminum foil, then exposed to dry heat in an oven at a mean temperature of 250° for 30 minutes to achieve sterility and depyrogenation (see [Dry-Heat Sterilization under Sterilization and Sterility Assurance of Compendial Articles \(1211\)](#) and [Bacterial Endotoxins Test \(85\)](#)). Such items are either used immediately or stored until use in an environment suitable for compounding Low-Risk Level CSPs and Medium-Risk Level CSPs.
3. Personnel ascertain from appropriate information sources that the sterile microporous membrane filter used to sterilize CSP solutions, during either compounding or administration, is chemically and physically compatible with the CSP.

#### sterilization of high-risk level csp by filtration

Commercially available sterile filters shall be approved for human-use applications in sterilizing pharmaceutical fluids. Sterile filters used to sterilize CSPs shall be pyrogen free and have a nominal pore size of 0.2 or 0.22 µm. They shall be certified by the manufacturer to retain at least 107 microorganisms of a strain of *Brevundimonas (Pseudomonas) diminuta* on each square centimeter of upstream filter surface area under conditions similar to those in which the CSPs will be sterilized (see [High-Risk Conditions in High-Risk Level CSPs](#)).

The compounding supervisor shall ensure, directly or from appropriate documentation, that the filters are chemically and physically stable at the pressure and temperature conditions to be used, that they have enough capacity to filter the required volumes, and that they will achieve sterility and maintain prefiltration pharmaceutical quality, including strength of ingredients of the specific CSP. The filter dimensions and liquid material to be sterile-filtered shall permit the sterilization process to be completed rapidly, without the replacement of the filter during the process. When CSPs are known to contain excessive particulate matter, a prefILTER of larger nominal pore size membrane is placed upstream from the sterilizing filter to remove gross particulate contaminants in order to maximize the efficiency of the sterilizing filter.

Filter units used to sterilize CSPs shall also be subjected to manufacturers' recommended integrity test, such as the bubble point test.

Compounding personnel shall ascertain that selected filters will achieve sterilization of the particular CSPs being sterilized. Large deviations from usual or expected chemical and physical properties of CSPs (e.g., water-miscible alcohols) may cause undetectable damage to filter integrity and shrinkage of microorganisms to sizes smaller than filter nominal pore size.

#### sterilization of high-risk level csp by steam

The process of thermal sterilization employing saturated steam under pressure, or autoclaving, is the preferred method to terminally sterilize aqueous preparations that have been verified to maintain their full chemical and physical stability under the conditions employed (see [Steam Sterilization under Sterilization and Sterility Assurance of Compendial Articles \(1211\)](#)). To achieve sterility, all materials are to be exposed to steam at 121° under a pressure of about 1 atmosphere or 15 psi for the duration verified by testing to achieve sterility of the items, which is usually 20 to 60 minutes for CSPs. An allowance shall be made for the time required for the material to reach 121° before the sterilization exposure duration is timed.

Not directly exposing items to pressurized steam may result in survival of microbial organisms and spores. Before their sterilization, plastic, glass, and metal devices are tightly wrapped in low-particle-shedding paper or fabrics or sealed in envelopes that prevent poststerilization microbial penetration. Immediately before filling ampuls and vials that will be steam sterilized, solutions are passed through a filter having a nominal pore size not larger than 1.2 µm for removal of particulate matter. Sealed containers shall be able to generate steam internally; thus, stoppered and crimped empty vials shall contain a small amount of moisture to generate steam.

The description of steam sterilization conditions and duration for specific CSPs shall be included in written documentation in the compounding facility. The effectiveness of steam sterilization shall be verified using appropriate BIs of *Bacillus stearothermophilus* (see [Biological Indicators \(1035\)](#)) and other confirmation methods such as temperature-sensing devices (see [Sterilization and Sterility Assurance of Compendial Articles \(1211\)](#) and [Sterility Tests \(71\)](#)).

#### sterilization of high-risk level csp by dry heat

Dry heat sterilization is usually done as a batch process in an oven designed for sterilization. Heated filtered air shall be evenly distributed throughout the chamber by a blower device. The oven should be equipped with a system for controlling temperature and exposure period. Sterilization by dry heat requires higher temperatures and longer exposure times than does sterilization by steam. Dry heat shall be used only for those materials that cannot be sterilized by steam, when either the moisture would damage the material or the material is impermeable. During sterilization, sufficient space shall be left between materials to allow for good circulation of the hot air. The description of dry heat sterilization conditions and duration for specific CSPs shall be included in written documentation in the compounding facility. The effectiveness of dry heat sterilization shall be verified using appropriate BIs of *Bacillus subtilis* (see [Biological Indicators \(1035\)](#)) and other confirmation methods such as temperature-sensing devices (see [Sterilization and Sterility Assurance of Compendial Articles \(1211\)](#) and [Sterility Tests \(71\)](#)). [note—Dry heat sterilization may be performed at a lower temperature than may be effective for depyrogenation].

#### Depyrogenation by Dry Heat

Dry heat depyrogenation shall be used to render glassware or containers such as vials free from pyrogens as well as viable microbes. A typical cycle would be 30 minutes at 250°. The description of the dry heat depyrogenation cycle and duration for specific load items shall be included in written documentation in the compounding facility. The effectiveness of the dry heat depyrogenation cycle shall be verified using endotoxin challenge vials (ECVs). The bacterial endotoxin test should be performed on the ECVs to verify that the cycle is capable of achieving a 3-log reduction in endotoxin (see [Sterilization and Sterility Assurance of Compendial Articles \(1211\)](#) and [Bacterial Endotoxins Test \(85\)](#)).

#### ENVIRONMENTAL QUALITY AND CONTROL

Achieving and maintaining sterility and overall freedom from contamination of a CSP is dependent on the quality status of the components incorporated, the process utilized, personnel performance, and the environmental conditions under which the process is performed. The standards required for the environmental conditions depend on the amount of exposure of the CSP to the immediate environment anticipated during processing. The quality and control of environmental conditions for each risk level of operation are explained in this section.

In addition, operations using nonsterile components require the use of a method of preparation designed to produce a sterile preparation.

#### Exposure of Critical Sites

Maintaining the sterility and cleanliness (i.e., freedom from sterile foreign materials) of critical sites is a primary safeguard for CSPs. Critical sites are locations that include any component or fluid pathway surfaces (e.g., vial septa, injection ports, beakers) or openings (e.g., opened ampuls, needle hubs) exposed and at risk of direct contact with air (e.g.,

...lient room or HEPA filtered), moisture (e.g., oral and mucosal secretions), or touch contamination. The risk of, or potential for, critical sites to be contaminated with microorganisms and foreign matter increases with increasing exposed area of the critical sites, the density or concentration of contaminants, and exposure duration to worse than ISO Class 5 (see [Table 1](#)) air. Examples include an opened ampul or vial stopper on a 10-mL or larger vial or an injection port on a package of intravenous solution having an area larger than the point of a needle or the tip of a syringe.

The nature of a critical site also affects the risk of contamination. The relatively rough, permeable surface of an elastomeric closure retains microorganisms and other contaminants after swabbing with a sterile 70% IPA pad more readily than does the smoother glass surface of the neck of an ampul. Therefore, the surface disinfection can be expected to be more effective for an ampul.

Protection of critical sites by precluding physical contact and airborne contamination shall be given the highest priority in sterile compounding practice. Airborne contaminants, especially those generated by sterile compounding personnel, are much more likely to reach critical sites than are contaminants that are adhering to the floor or other surfaces below the work level. Furthermore, large and high-density particles that are generated and introduced by compounding manipulations and personnel have the potential to settle on critical sites even when those critical sites are exposed within ISO Class 5 (see [Table 1](#)) air.

#### ISO Class 5 Air Sources, Buffer Areas, and Ante-Areas

The most common sources of ISO Class 5 (see [Table 1](#)) air quality for exposure of critical sites are horizontal and vertical LAFWs, CAIs, and CACIs. A clean room (see [Microbiological Evaluation of Clean Rooms and Other Controlled Environments](#) (1116)) is a compounding environment that is supplied with HEPA or HEPA-filtered air that meets ISO Class 7 (see [Table 1](#)), the access to which is limited to personnel trained and authorized to perform sterile compounding and facility cleaning. A buffer area is an area that provides at least ISO Class 7 (see [Table 1](#)) air quality.

[Figure 1](#) is a conceptual representation of the placement of an ISO Class 5 (see [Table 1](#)) PEC in a segregated compounding area used for low-risk level CSPs with 12-hour or less BUD. This plan depicts the most critical operation area located within the PEC in a designated area (see definition of Segregated Compounding Area) separated from activities not essential to the preparation of CSPs. Placement of devices (e.g., computers, printers) and objects (e.g., carts, cabinets) that are not essential to compounding in the segregated area should be restricted or limited, depending on their effect on air quality in the ISO Class 5 (see [Table 1](#)) PEC.

Conceptual representation of USP Chapter <797> facility requirements

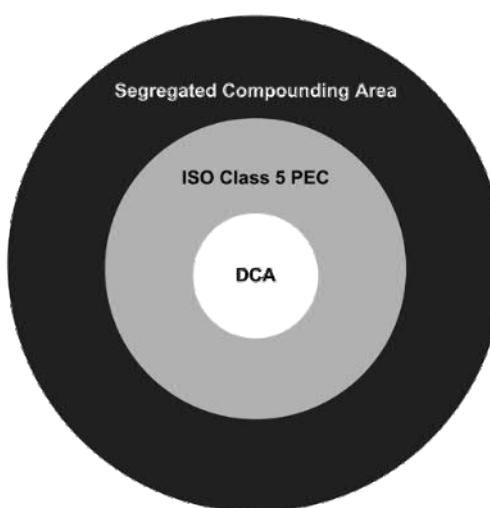

Figure 1. Conceptual representation of the placement of an ISO Class 5 PEC in a segregated compounding area used for low-risk level CSPs with 12-hour or less BUD.

[Figure 2](#) is a conceptual representation of the arrangement of a facility for preparation of CSPs categorized as low-, medium-, and high-risk level. The quality of the environmental air increases with movement from the outer boundary to the direct compounding area (DCA). Placement of devices in ante-areas and buffer areas is dictated by their effect on the designated environmental quality of atmospheres and surfaces, which shall be verified by monitoring (see Viable and Nonviable Environmental Sampling (ES) Testing). It is the responsibility of each compounding facility to ensure that each source of ISO Class 5 (see [Table 1](#)) environment for exposure of critical sites and sterilization by filtration is properly located, operated, maintained, monitored, and verified.

Conceptual representation of USP Chapter <797> facility requirements

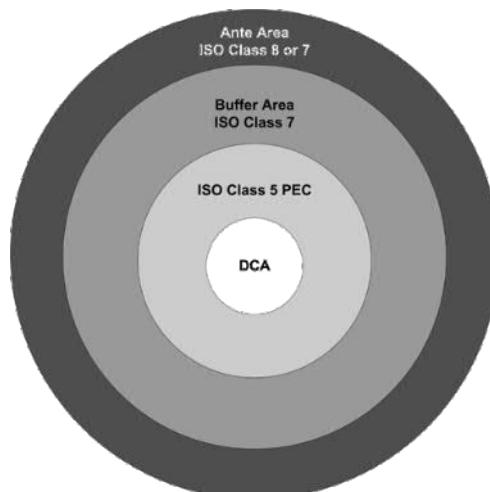

Figure 2. Conceptual representation of the arrangement of a facility for preparation of CSPs categorized as low-, medium-, and high-risk level.

Placement of devices (e.g., computers, printers) and objects (e.g., carts, cabinets) that are not essential to compounding in buffer areas is dictated by their effect on the required environmental quality of air atmospheres and surfaces, which shall be verified by monitoring (see Viable and Nonviable Environmental Sampling (ES) Testing). It is the responsibility of each compounding facility to ensure that each source of ISO Class 5 (see [Table 1](#)) environment for exposure of critical sites and sterilization by filtration is properly located, operated, maintained, monitored, and verified.

#### Facility Design and Environmental Controls

Compounding facilities are physically designed and environmentally controlled to minimize airborne contamination from contacting critical sites. These facilities shall also provide a comfortable and well-lighted working environment, which typically includes a temperature of 20° or cooler, to maintain comfortable conditions for compounding personnel to perform flawlessly when attired in the required aseptic compounding garb. PECs typically include, but are not limited to, LAFWs, BSCs, CAIs, and CACIs, which provide an ISO Class 5 (see [Table 1](#)) environment for the exposure of critical sites. PECs shall maintain ISO Class 5 (see [Table 1](#)) or better conditions for 0.5-μm particles (dynamic operating conditions) while compounding CSPs. Secondary engineering controls such as buffer areas and ante-areas generally serve as a core for the location of the PEC. Buffer areas are designed to maintain at least ISO Class 7 (see [Table 1](#)) conditions for 0.5-μm particles under dynamic conditions and ISO Class 8 (see [Table 1](#)) conditions for 0.5-μm and larger particles under dynamic conditions for the ante-areas. Airborne contamination control is achieved in the PEC through the use of HEPA filters. The airflow in the PEC shall be unidirectional (laminar flow), and because of the particle collection efficiency of the filter, the "first air" at the face of the filter is, for the purposes of aseptic compounding, free from airborne particulate contamination. HEPA-filtered air shall be supplied in critical areas (ISO Class 5, see [Table 1](#)) at a velocity sufficient to sweep particles away from the compounding area and maintain unidirectional airflow during operations. Proper design and control prevents turbulence and stagnant air in the critical area. In situ air pattern analysis via smoke studies shall be conducted at the critical area to demonstrate unidirectional airflow and sweeping action over and away from the product under dynamic conditions.

The principles of HEPA-filtered unidirectional airflow in the work environment shall be understood and practiced in the compounding process in order to achieve the desired environmental conditions. Policies and procedures for maintaining and working within the PEC area shall be written and followed. The policies and procedures will be determined by the scope and risk levels of the aseptic compounding activities utilized during the preparation of the CSPs. The CSP work environment is designed to have the cleanest work surfaces (PEC) located in a buffer area. The buffer area shall maintain at least ISO Class 7 (see [Table 1](#)) conditions for 0.5-μm and larger particles under dynamic operating conditions. The room shall be segregated from surrounding, unclassified spaces to reduce the risk of contaminants being blown, dragged, or otherwise introduced into the filtered unidirectional airflow

environment, and this segregation shall be continuously monitored. For rooms providing a physical separation through the use of walls, doors, and pass-throughs, a minimum differential positive pressure of 0.02- to 0.05-inch water column is required. For buffer areas not physically separated from the ante-areas, the principle of displacement airflow shall be employed. This concept utilizes a low pressure differential, high airflow principle. Using displacement airflow typically requires an air velocity of 40 ft per minute or more from the buffer area across the line of demarcation into the ante-area.

The displacement concept shall not be used for high-risk compounding.<sup>8</sup> The PEC shall be placed within a buffer area in such a manner as to avoid conditions that could adversely affect their operation. For example, strong air currents from opened doors, personnel traffic, or air streams from the HVAC systems can disrupt the unidirectional airflow in open-faced workbenches. The operators may also create disruptions in airflow by their own movements and by the placement of objects onto the work surface. The PEC shall be placed out of the traffic flow and in a manner to avoid disruption from the HVAC system and room cross-drafts. Room air exchanges are typically expressed as ACPHs. Adequate HEPA-filtered airflow supplied to the buffer area and ante-area is required to maintain cleanliness classification during operational activity through the number of ACPHs. Factors that should be considered when determining air-change requirements include number of personnel working in the room and compounding processes that generate particulates, as well as temperature effects. An ISO Class 7 (see [Table 1](#)) buffer area and ante-area supplied with HEPA-filtered air shall receive an ACPH of not less than 30. The PEC is a good augmentation to generating air changes in the air supply of an area but cannot be the sole source of HEPA-filtered air. If the area has an ISO Class 5 (see [Table 1](#)) recirculating device, a minimum of 15 ACPHs through the area supply HEPA filters is adequate, providing the combined ACPH is not less than 30. More air changes may be required, depending on the number of personnel and processes. HEPA-filtered supply air shall be introduced at the ceiling, and returns should be mounted low on the wall, creating a general top-down dilution of area air with HEPA-filtered make-up air. Ceiling-mounted returns are not recommended. All HEPA filters should be efficiency tested using the most penetrating particle size and should be leak tested at the factory and then leak tested again in situ after installation.<sup>2</sup>

Activities and tasks carried out within the buffer area shall be limited to only those necessary when working within a controlled environment. Only the furniture, equipment, supplies, and other material required for the compounding activities to be performed shall be brought into the area, and they shall be nonpermeable, nonshedding, cleanable, and resistant to disinfectants. Whenever such items are brought into the area, they shall first be cleaned and disinfected. Whenever possible, equipment and other items used in the buffer area shall not be taken out of the area except for calibration, servicing, or other activities associated with the proper maintenance of the item.

The surfaces of ceilings, walls, floors, fixtures, shelving, counters, and cabinets in the buffer area shall be smooth, impervious, free from cracks and crevices, and nonshedding, thereby promoting cleanability and minimizing spaces in which microorganisms and other contaminants may accumulate. The surfaces shall be resistant to damage by disinfectant agents. Junctures of ceilings to walls shall be coved or caulked to avoid cracks and crevices where dirt can accumulate. If ceilings consist of inlaid panels, the panels shall be impregnated with a polymer to render them impervious and hydrophobic, and they shall be caulked around each perimeter to seal them to the support frame. Walls may be constructed of flexible material (e.g., heavy gauge polymer), panels locked together and sealed, or of epoxy-coated gypsum board. Preferably, floors are overlaid with wide sheet vinyl flooring with heat-welded seams and coving to the sidewall. Dust-collecting overhangs, such as ceiling utility pipes, and ledges, such as windowsills, should be avoided. The exterior lens surface of ceiling lighting fixtures should be smooth, mounted flush, and sealed. Any other penetrations through the ceiling or walls shall be sealed. The buffer area shall not contain sources of water (sinks) or floor drains. Work surfaces shall be constructed of smooth, impervious materials, such as stainless steel or molded plastic, so that they are easily cleaned and disinfected. Carts should be of stainless steel wire, nonporous plastic, or sheet metal construction with good quality, cleanable casters to promote mobility. Storage shelving, counters, and cabinets shall be smooth, impervious, free from cracks and crevices, nonshedding, cleanable, and disinfectable; their number, design, and manner of installation shall promote effective cleaning and disinfection.

#### Placement of Primary Engineering Controls

PECs (LAFWs, BSCs, CAIs, and CACIs) shall be located within a restricted access ISO Class 7 (see [Table 1](#)) buffer area (see [Figure 1](#)), with the following CAI/CACI exceptions below:

- Only authorized personnel and materials required for compounding and cleaning shall be permitted in the buffer area.
- Presterilization procedures for high-risk level CSPs, such as weighing and mixing, shall be completed in no worse than an ISO Class 8 (see [Table 1](#)) environment.
- PECs shall be located out of traffic patterns and away from room air currents that could disrupt the intended airflow patterns.

CAIs and CACIs shall be placed in an ISO Class 7 (see [Table 1](#)) buffer area unless they meet all of the following conditions:

- The isolator shall provide isolation from the room and maintain ISO Class 5 (see [Table 1](#)) during dynamic operating conditions, including transferring ingredients, components, and devices into and out of the isolator and during preparation of CSPs.
- Particle counts sampled approximately 6 to 12 inches upstream of the critical exposure site shall maintain ISO Class 5 (see [Table 1](#)) levels during compounding operations.
- Not more than 3520 particles (0.5 μm and larger) per m<sup>3</sup> shall be counted during material transfer, with the particle counter probe located as near to the transfer door as possible without obstructing the transfer.<sup>8</sup>

It is incumbent on the compounding personnel to obtain documentation from the manufacturer that the CAI/CACI will meet this standard when located in environments where the background particle counts exceed ISO Class 8 (see [Table 1](#)) for 0.5-μm and larger particles. When isolators are used for sterile compounding, the recovery time to achieve ISO Class 5 (see [Table 1](#)) air quality shall be documented and internal procedures developed to ensure that adequate recovery time is allowed after material transfer before and during compounding operations.

If the PEC is a CAI or CACI that does not meet the requirements above or is a LAFW or BSC that cannot be located within an ISO Class 7 (see [Table 1](#)) buffer area, then only low-risk level nonhazardous and radiopharmaceutical CSPs pursuant to a physician order for a specific patient may be prepared, and administration of the CSP shall commence within 12 hours of preparation or as recommended in the manufacturer's package insert, whichever is less.

#### Viable and Nonviable Environmental Sampling (ES) Testing

The ES program should provide information to staff and leadership to demonstrate that the PEC is maintaining an environment within the compounding area that consistently ensures

Acceptably low viable and nonviable particle levels. The compounding area includes the ISO Class 5 (see [Table 1](#)) PEC (LAFWs, BSCs, CAIs, and CACIs), buffer areas, ante-areas, and segregated compounding areas.

Environmental sampling shall occur as part a comprehensive quality management program and shall occur minimally under any of the following conditions:

- as part of the commissioning and certification of new facilities and equipment;
- following any servicing of facilities and equipment;
- as part of the re-certification of facilities and equipment (i.e., every 6 months);
- in response to identified problems with end products or staff technique; or
- in response to issues with CSPs, observed compounding personnel work practices, or patient-related infections (where the CSP is being considered as a potential source of the infection).

environmental nonviable particle testing program

A program to sample nonviable airborne particles differs from that for viable particles in that it is intended to directly measure the performance of the engineering controls used to create the various levels of air cleanliness, for example, ISO Class 5, 7, or 8 (see [Table 1](#)).

Engineering Control Performance Verification— PECs (LAFWs, BSCs, CAIs, and CACIs) and secondary engineering controls (buffer and ante-areas) are essential components of the overall contamination control strategy for aseptic compounding. As such, it is imperative that they perform as designed and that the resulting levels of contamination be within acceptable limits. Certification procedures such as those outlined in Certification Guide for Sterile Compounding Facilities (CAG-003-2006)<sup>8</sup> shall be performed by a qualified individual no less than every 6 months and whenever the device or room is relocated or altered or major service to the facility is performed.

Total Particle Counts— Certification that each ISO classified area, for example, ISO Class 5, 7, and 8 (see [Table 1](#)), is within established guidelines shall be performed no less than every 6 months and whenever the LAFW, BSC, CAI, or CACI is relocated or the physical structure of the buffer area or ante-area has been altered. Testing shall be performed by qualified operators using current, state-of-the-art electronic equipment with results of the following:

- ISO Class 5: not more than 3520 particles 0.5  $\mu$ m and larger size per cubic meter of air for any LAFW, BSC, CAI, and CACI;
- ISO Class 7: not more than 352,000 particles of 0.5  $\mu$ m size and larger per cubic meter of air for any buffer area;
- ISO Class 8: not more than 3,520,000 particles or 0.5  $\mu$ m size and larger per cubic meter of air for any ante-area.

All certification records shall be maintained and reviewed by supervising personnel or other designated employees to ensure that the controlled environments comply with the proper air cleanliness, room pressures, and ACPHs.

pressure differential monitoring

A pressure gauge or velocity meter shall be installed to monitor the pressure differential or airflow between the buffer area and the ante-area and between the ante-area and the general environment outside the compounding area. The results shall be reviewed and documented on a log at least every work shift (minimum frequency shall be at least daily) or by a continuous recording device. The pressure between the ISO Class 7 (see [Table 1](#)) and the general pharmacy area shall not be less than 5 Pa (0.02 inch water column). In facilities where low- and medium-risk level CSPs are prepared, differential airflow shall maintain a minimum velocity of 0.2 meters per second (40 feet per minute) between buffer area and ante-area.

environmental viable airborne particle testing program

The risk of contaminating a CSP prepared under low-risk level and medium-risk level conditions is highly dependent on proper hand hygiene and garbing practices, compounding personnel aseptic technique, and the presence of surface contamination, assuming that all work is performed in a certified and properly functioning ISO Class 5 (see [Table 1](#)) PEC and secondary engineering controls, ISO Class 7 (see [Table 1](#)) buffer area, and ISO Class 8 (see [Table 1](#)) ante-area. High-risk level CSPs pose the greatest threat to patients because compounding personnel are tasked with the requirement of processing nonsterile components and devices in order to achieve sterility.

A sampling program in conjunction with an observational audit is designed to evaluate the competency of compounding personnel work practices, allowing for the implementation of corrective actions on an ongoing basis (see Personnel Training and Competency Evaluation of Garbing, Aseptic Work Practices and Cleaning/Disinfection Procedures).

**Sampling Plan**— An appropriate environmental sampling plan shall be developed for airborne viable particles based on a risk assessment of compounding activities performed.

Selected sampling sites shall include locations within each ISO Class 5 (see [Table 1](#)) environment and in the ISO Class 7 and 8 (see [Table 1](#)) areas and in the segregated compounding areas at greatest risk of contamination (e.g., work areas near the ISO Class 5 [see [Table 1](#)] environment, counters near doors, pass-through boxes). The plan shall include sample location, method of collection, frequency of sampling, volume of air sampled, and time of day as related to activity in the compounding area and action levels.

Review of the data generated during a sampling event may detect elevated amounts of airborne microbial bioburden; such changes may be indicative of adverse changes within the environment. It is recommended that compounding personnel refer to [Microbiological Evaluation of Clean Rooms and Other Controlled Environments](#) (1116) and the CDC's "Guidelines for Environmental Infection Control in Healthcare Facilities, 2003" for more information.

**Growth Medium**— A general microbiological growth medium such as Soybean–Casein Digest Medium shall be used to support the growth of bacteria. Malt extract agar or some other media that support the growth of fungi shall be used in high-risk level compounding environments. Media used for surface sampling must be supplemented with additives to neutralize the effects of disinfecting agents (e.g., TSA with lecithin and polysorbate 80).

**Viable Air Sampling**— Evaluation of airborne microorganisms using volumetric collection methods in the controlled air environments (LAFWs, CAIs, clean room or buffer areas, and ante-areas) shall be performed by properly trained individuals for all compounding risk levels.

Impaction shall be the preferred method of volumetric air sampling. Use of settling plates for qualitative air sampling may not be able to determine adequately the quality of air in the controlled environment. The settling of particles by gravity onto culture plates depends on the particle size and may be influenced by air movement. Consequently, the number of colony-forming units (cfu) on a settling plate may not always relate to the concentrations of viable particles in the sampled environment.

For low-, medium-, and high-risk level compounding, air sampling shall be performed at locations that are prone to contamination during compounding activities and during other activities such as staging, labeling, gowning, and cleaning. Locations shall include zones of air backwash turbulence within LAFW and other areas where air backwash turbulence may enter the compounding area (doorways, in and around ISO Class 5 [see [Table 1](#)] PEC and environments). Consideration should be given to the overall effect the chosen sampling method will have on the unidirectional airflow within a compounding environment.

For low-risk level CSPs with 12-hour or less BUD prepared in a PEC (LAFWs, BSCs, CAIs) that maintains an ISO Class 5 (see [Table 1](#)), air sampling shall be performed at locations inside the ISO Class 5 (see [Table 1](#)) environment and other areas that are in close proximity to the ISO Class 5 (see [Table 1](#)) environment during the certification of the PEC.

**Air Sampling Devices**— There are a number of manufacturers of electronic air sampling equipment. It is important that personnel refer to the manufacturer's recommended procedures when using the equipment to perform volumetric air sampling procedures. The instructions in the manufacturer's user's manual for verification and use of electric air samplers that actively collect volumes of air for evaluation must be followed. A sufficient volume of air (400 to 1000 liters) shall be tested at each location in order to maximize sensitivity. The volumetric air sampling devices need to be serviced and calibrated as recommended by the manufacturer.

It is recommended that compounding personnel also refer to Methodology and Instrumentation for Quantitation of Viable Airborne Microorganisms under [Microbiological Evaluation of Clean Rooms and Other Controlled Environments](#) (1116), which provides more information on the use of volumetric air samplers and volume of air that should be sampled to detect environmental bioburden excursions.

**Air Sampling Frequency and Process**— Air sampling shall be performed at least semiannually (i.e., every 6 months) as part of the re-certification of facilities and equipment. If compounding occurs in multiple locations within an institution (e.g., main pharmacy, satellites), environmental sampling is required for each individual compounding area. A sufficient volume of air shall be sampled and the manufacturer's guidelines for use of the electronic air sampling equipment followed. Any facility construction or equipment servicing may require that air sampling be performed during these events.

...cubation Period— At the end of the designated sampling or exposure period for air sampling activities, the microbial growth media plates are recovered and their covers secured (e.g., taped), and they are inverted and incubated at a temperature and for a time period conducive to multiplication of microorganisms. TSA should be incubated at 30° to 35° for 48 to 72 hours. Malt extract agar or other suitable fungal media should be incubated at 26° to 30° for 5 to 7 days. The number of discrete colonies of microorganisms are counted and reported as cfu and documented on an environmental sampling form. Counts from air sampling need to be transformed into cfu per cubic meter of air and evaluated for adverse trends.

Action Levels, Documentation, and Data Evaluation— The value of viable microbial sampling of the air in the compounding environment is realized when the data are used to identify and correct an unacceptable situation. Sampling data shall be collected and reviewed on a periodic basis as a means of evaluating the overall control of the compounding environment.

If an activity consistently shows elevated levels of microbial growth, competent microbiology personnel shall be consulted.

Any cfu count that exceeds its respective action level (see [Table 2](#)) should prompt a re-evaluation of the adequacy of personnel work practices, cleaning procedures, operational procedures, and air filtration efficiency within the aseptic compounding location. An investigation into the source of the contamination shall be conducted. Sources could include HVAC systems, damaged HEPA filters, and changes in personnel garbing or work practices. The source of the problem shall be eliminated, the affected area cleaned, and resampling performed.

Counts of cfu are to be used as an approximate measure of the environmental microbial bioburden. Action levels are determined on the basis of cfu data gathered at each sampling location and trended over time. The numbers in [Table 2](#) should be used only as guidelines. Regardless of the number of cfu identified in the pharmacy, further corrective actions will be dictated by the identification of microorganisms recovered (at least the genus level) by an appropriate credentialed laboratory of any microbial bioburden captured as a cfu using an impaction air sampler. Highly pathogenic microorganisms (e.g., Gram-negative rods, coagulase positive staphylococcus, molds and yeasts) can be potentially fatal to patients receiving CSPs and must be immediately remedied, regardless of cfu count, with the assistance of a competent microbiologist, infection control professional, or industrial hygienist.

Table 2. Recommended Action Levels for Microbial Contamination\*  
†(cfu per cubic meter [1000 liters] of air per plate)

Classification	Air Sample†
ISO Class 5	> 1
ISO Class 7	> 10
ISO Class 8 or worse	> 100

\* Guidance for Industry—Sterile Drug Products Produced by Aseptic Processing—Current Good Manufacturing Practice—US HHS, FDA September 2004.

#### Additional Personnel Requirements

Food, drinks, and materials exposed in patient care and treatment areas shall not enter ante-areas, buffer areas, or segregated compounding areas where components and ingredients of CSPs are present. When compounding activities require the manipulation of a patient's blood-derived or other biological material (e.g., radiolabeling a patient's or donor's white blood cells), the manipulations shall be clearly separated from routine material-handling procedures and equipment used in CSP preparation activities, and they shall be controlled by specific SOPs in order to avoid any cross-contamination. Packaged compounding supplies and components, such as needles, syringes, tubing sets, and small- and large-volume parenterals, should be uncartoned and wiped down with a disinfectant that does not leave a residue (e.g., sterile 70% IPA), when possible in an ante-area of ISO Class 8 (see [Table 1](#)) air quality, before being passed into the buffer areas. Personnel hand hygiene and garbing procedures are also performed in the ante-area, which may contain a sink that enables hands-free use with a closed system of soap dispensing to minimize the risk of extrinsic contamination. There shall be some demarcation designation that separates the ante-area from the buffer area. Adequate provision for performing antiseptic hand cleansing using an alcohol-based surgical hand scrub with persistent activity followed by the donning of sterile gloves should be provided after entry into the buffer area.

#### Cleaning and Disinfecting the Compounding Area

Environmental contact is a major source of microbial contamination of CSPs. Consequently, scrupulous attention to cleaning and disinfecting the sterile compounding areas is required to minimize this as a source of CSP contamination.

The cleaning and disinfecting practices and frequencies in this section apply to ISO Class 5 (see [Table 1](#)) compounding areas for exposure of critical sites as well as buffer areas, ante-areas, and segregated compounding areas. Compounding personnel are responsible for ensuring that the frequency of cleaning is in accordance with the requirements stated in [Table 3](#) and determining the cleaning and disinfecting products to be used (see Appendix II). Any organizational or institutional policies regarding disinfectant selection should be considered by compounding personnel. All cleaning and disinfecting practices and policies for the compounding of CSPs shall be included in written SOPs and shall be followed by all compounding personnel.

The selection and use of disinfectants in healthcare facilities is guided by several properties, such as microbicidal activity, inactivation by organic matter, residue, and shelf life (see Appendix II). In general, highly toxic disinfectants, such as glutaraldehyde, are not used on housekeeping surfaces (e.g., floors, countertops). Many disinfectants registered by the EPA are one-step disinfectants. This means that the disinfectant has been formulated to be effective in the presence of light to moderate soiling without a pre-cleaning step.

Surfaces in LAFWs, BSCs, CAIs, and CACIs, which are intimate to the exposure of critical sites, require disinfecting more frequently than do housekeeping surfaces such as walls and ceilings. Disinfecting sterile compounding areas shall occur on a regular basis at the intervals noted in [Table 3](#) when spills occur, when the surfaces are visibly soiled, and when microbial contamination is known to have been or is suspected of having been introduced into the compounding areas.

When the surface to be disinfected has heavy soiling, a cleaning step is recommended prior to the application of the disinfectant. Trained compounding personnel are responsible for developing, implementing, and practicing the procedures for cleaning and disinfecting the DCAs written in the SOPs. Cleaning and disinfecting shall occur before compounding is performed. Items shall be removed from all areas to be cleaned, and surfaces shall be cleaned by removing loose material and residue from spills; for example, water-soluble solid residues are removed with sterile water (for injection or irrigation) and low-shedding wipes. This shall be followed by wiping with a residue-free disinfecting agent such as sterile 70% IPA, which is allowed to dry before compounding begins.

Cleaning and disinfecting surfaces in the LAFWs, BSCs, CAIs, and CACIs are the most critical practices before the preparation of CSPs. Consequently, such surfaces shall be cleaned and disinfected frequently, including at the beginning of each work shift, before each batch preparation is started, every 30 minutes during continuous compounding periods of individual CSPs, when there are spills, and when surface contamination is known or suspected from procedural breaches.

Work surfaces in the ISO Class 7 (see [Table 1](#)) buffer areas and ISO Class 8 (see [Table 1](#)) ante-areas as well as segregated compounding areas shall be cleaned and disinfected at least daily, and dust and debris shall be removed when necessary from storage sites for compounding ingredients and supplies using a method that does not degrade the ISO Class 7 or 8 (see [Table 1](#)) air quality (see [Disinfectants and Antiseptics](#) (1072)).

Table 3. Minimum Frequency of Cleaning and Disinfecting Compounding Areas

Site	Minimum Frequency
ISO Class 5 (see <a href="#">Table 1</a> ) Primary Engineering Control (e.g., LAFW, BSC, CAI, CACI)	At the beginning of each shift, before each batch, not longer than 30 minutes following the previous surface disinfection when ongoing compounding activities are occurring, after spills, and when surface contamination is known or suspected
Counters and easily cleanable work surfaces	Daily
Floors	Daily
Walls	Monthly
Ceilings	Monthly
Storage shelving	Monthly

Floors in the buffer or clean area, ante-area, and segregated compounding area are cleaned by mopping with a cleaning and disinfecting agent once daily at a time when no aseptic operations are in progress. Mopping shall be performed by trained personnel using approved agents and procedures described in the written SOPs. It is incumbent on compounding personnel to ensure that such cleaning is performed properly. In the buffer or clean area, ante-area, and segregated compounding area, walls, ceilings, and shelving shall be cleaned

disinfected monthly. Cleaning and disinfecting agents are to be used with careful consideration of compatibilities, effectiveness, and inappropriate or toxic residues (see Appendix II). Their schedules of use and methods of application shall be in accordance with written SOPs and followed by custodial or compounding personnel.

All cleaning materials, such as wipers, sponges, and mops, shall be nonshedding, preferably composed of synthetic micro fibers, and dedicated to use in the buffer or clean area, ante-area, and segregated compounding areas and shall not be removed from these areas except for disposal. Floor mops may be used in both the buffer or clean area and ante-area, but only in that order. Ideally, all cleaning tools are discarded after one use by collection in suitable plastic bags and removed with minimal agitation. If cleaning materials (e.g., mops) are reused, procedures shall be developed (based on manufacturers' recommendations) that ensure that the effectiveness of the cleaning device is maintained and that repeated use does not add to the bioburden of the area being cleaned.

Supplies and equipment removed from shipping cartons shall be wiped with a suitable disinfecting agent (e.g., sterile 70% IPA) delivered from a spray bottle or other suitable delivery method. After the disinfectant is sprayed or wiped on a surface to be disinfected, the disinfectant shall be allowed to dry, during which time the item shall not be used for compounding purposes.

Wiping with small sterile 70% IPA swabs that are commercially available in individual foil-sealed packages (or a comparable method) is preferred for disinfecting entry points on bags and vials, allowing the IPA to dry before piercing stoppers with sterile needles and breaking necks of ampuls. The surface of the sterile 70% IPA swabs used for disinfecting entry points of sterile packages and devices shall not contact any other object before contacting the surface of the entry point. Sterile 70% IPA wetted gauze pads or other particle-generating material shall not be used to disinfect the sterile entry points of packages and devices.

When sterile supplies are received in sealed pouches designed to keep them sterile until opening, the sterile supplies may be removed from the covering pouches as the supplies are introduced into the ISO Class 5 (see [Table 1](#)) PEC (LAFW, BSC, CAI, CACI) without the need to disinfect the individual sterile supply items. No shipping or other external cartons may be taken into the buffer or clean area or segregated compounding area.

#### Personnel Cleansing and Garbing

The careful cleansing of hands and arms and the correct donning of PPE by compounding personnel constitute the first major step in preventing microbial contamination in CSPs. Personnel shall also be thoroughly competent and highly motivated to perform flawless aseptic manipulations with ingredients, devices, and components of CSPs. Squamous cells are normally shed from the human body at a rate of 106 or more per hour, and those skin particles are laden with microorganisms.<sup>10,11</sup> When individuals are experiencing rashes, sunburn, weeping sores, conjunctivitis, active respiratory infection, as well as when they wear cosmetics, they shed these particles at even higher rates. Particles shed from compounding personnel pose an increased risk of microbial contamination of critical sites of CSPs. Therefore, compounding personnel with such conditions as mentioned above shall be excluded from working in ISO Class 5 (see [Table 1](#)) and ISO Class 7 (see [Table 1](#)) compounding areas until their conditions are remedied.

Before entering the buffer area or segregated compounding area (see Low-Risk Level CSPs with 12-Hour or Less BUD), compounding personnel shall remove personal outer garments (e.g., bandannas, coats, hats, jackets, scarves, sweaters, vests); all cosmetics, because they shed flakes and particles; and all hand, wrist, and other visible jewelry or piercings (e.g., earrings, lip or eyebrow piercings) that can interfere with the effectiveness of PPE (e.g., fit of gloves and cuffs of sleeves). The wearing of artificial nails or extenders is prohibited while working in the sterile compounding environment. Natural nails shall be kept neat and trimmed.

Personnel shall don the following PPE in an order that proceeds from those activities considered the dirtiest to those considered the cleanest. Garbing activities considered the dirtiest include donning of dedicated shoes or shoe covers, head and facial hair covers (e.g., beard covers in addition to face masks), and face masks/eye shields. Eye shields are optional unless working with irritants such as germicidal disinfecting agents or when preparing hazardous drugs.

After donning dedicated shoes or shoe covers, head and facial hair covers, and face masks, a hand cleansing procedure shall be performed by removing debris from underneath fingernails using a nail cleaner under running warm water followed by vigorous hand washing. Hands and forearms shall be washed to the elbows for at least 30 seconds with soap (either nonantimicrobial or antimicrobial) and water while in the ante-area. The use of antimicrobial scrub brushes is not recommended because they can cause skin irritation and skin damage. Hands and forearms to the elbows will be completely dried using either lint-free disposable towels or an electronic hand dryer. After completion of hand washing, a nonshedding gown with sleeves that fit snugly around the wrists and enclosed at the neck is donned. Gowns designated for buffer area use shall be worn, and preferably they should be disposable. If reusable gowns are worn, they should be laundered appropriately for buffer area use.

Once inside the buffer area or segregated compounding area (see Low-Risk Level CSPs with 12-Hour or Less BUD), and prior to donning sterile powder-free gloves, antiseptic hand cleansing shall be performed using a waterless alcohol-based surgical hand scrub with persistent activity<sup>12</sup> following manufacturers' recommendations. Hands are allowed to dry thoroughly before donning sterile gloves.

Sterile gloves shall be the last item donned before compounding begins. Gloves become contaminated when they contact nonsterile surfaces during compounding activities. Disinfection of contaminated gloved hands may be accomplished by wiping or rubbing sterile 70% IPA to all contact surface areas of the gloves and letting the gloved hands dry thoroughly. Only use gloves that have been tested for compatibility with alcohol disinfection by the manufacturer. Routine application of sterile 70% IPA shall occur throughout the compounding process and whenever nonsterile surfaces (e.g., vials, counter tops, chairs, carts) are touched. Gloves on hands shall also be routinely inspected for holes, punctures, or tears and replaced immediately if such are detected. Antiseptic hand cleansing shall be performed as indicated above. Compounding personnel shall be trained and evaluated in the avoidance of touching critical sites.

When compounding personnel exit the compounding area during a work shift, the exterior gown may be removed and retained in the compounding area if not visibly soiled, to be re-donned during that same work shift only. However, shoe covers, hair and facial hair covers, face masks/eye shields, and gloves shall be replaced with new ones before re-entering the compounding area, and proper hand hygiene shall be performed.

During high-risk compounding activities that precede terminal sterilization, such as weighing and mixing of nonsterile ingredients, compounding personnel shall be garbed and gloved the same as when performing compounding in an ISO Class 5 (see [Table 1](#)) environment. Properly garbed and gloved compounding personnel who are exposed to air quality that is either known or suspected to be worse than ISO Class 7 (see [Table 1](#)) shall re-garb PPE along with washing their hands properly, performing antiseptic hand cleansing with a waterless alcohol-based surgical hand scrub, and donning sterile gloves upon re-entering the ISO Class 7 (see [Table 1](#)) buffer area. When CAIs and CACIs are the source of the ISO Class 5 (see [Table 1](#)) environment, the garbing and gloving requirements for compounding personnel should be as described above, unless the isolator manufacturer can provide written documentation based on validated environmental testing that any component(s) of PPE or personnel cleansing are not required.

#### Personnel Training and Competency Evaluation of Garbing, Aseptic Work Practices, and Cleaning/Disinfection Procedures

Personnel who prepare CSPs shall be trained conscientiously and skillfully by expert personnel and through multimedia instructional sources and professional publications in the theoretical principles and practical skills of garbing procedures, aseptic work practices, achieving and maintaining ISO Class 5 (see [Table 1](#)) environmental conditions, and cleaning and disinfection procedures. This training shall be completed and documented before any compounding personnel begin to prepare CSPs. Compounding personnel shall complete didactic training, pass written competence assessments, undergo skill assessment using observational audit tools, and media-fill testing (see Appendices III–V).

Media-fill testing of aseptic work skills shall be performed initially before beginning to prepare CSPs and at least annually thereafter for low- and medium-risk level compounding and semiannually for high-risk level compounding.

Compounding personnel who fail written tests or observational audits or whose media-fill test vials have one or more units showing visible microbial contamination shall be re-instructed and re-evaluated by expert compounding personnel to ensure correction of all aseptic work practice deficiencies. Compounding personnel shall pass all evaluations prior to resuming compounding of sterile preparations. In addition to didactic evaluation and aseptic media fill, compounding personnel must demonstrate proficiency of proper hand hygiene, garbing, and consistent cleaning procedures.

In the event that cleaning and disinfecting procedures are also performed by other support personnel (e.g., institutional environmental services, housekeeping), thorough training of proper hand hygiene, garbing, and cleaning and disinfection procedures shall be done by a qualified aseptic compounding expert. After completion of training, support personnel shall routinely undergo performance evaluation of proper hand hygiene, garbing, and all applicable cleaning and disinfecting procedures conducted by a qualified aseptic compounding expert.

competency evaluation of garbing and aseptic work practice

The risk of contaminating a CSP prepared under low-risk level and medium-risk level conditions is highly dependent on proper hand hygiene and garbing practices, compounding personnel aseptic technique, and the presence of surface contamination, assuming that all work is performed in a certified and properly functioning ISO Class 5 (see [Table 1](#)) PEC and secondary engineering controls, ISO Class 7 (see [Table 1](#)) buffer area, and ISO Class 8 (see [Table 1](#)) ante-area. High-risk level CSPs pose the greatest threat to patients because compounding personnel are tasked with the requirement of processing nonsterile components and devices in order to achieve sterility. Compounding personnel shall be evaluated initially prior to beginning compounding CSPs and whenever an aseptic media fill is performed using a form such as the Sample Form for Assessing Hand Hygiene and Garbing

Related Practices of Compounding Personnel (see Appendix III) and the personnel glove fingertip sampling procedures indicated below.

**Aseptic Work Practice Assessment and Evaluation via Personnel Glove Fingertip Sampling**— Sampling of compounding personnel glove fingertips shall be performed for all CSP risk level compounding because direct touch contamination is the most likely source of introducing microorganisms into CSPs prepared by humans. Glove fingertip sampling shall be used to evaluate the competency of personnel in performing hand hygiene and garbing procedures in addition to educating compounding personnel on proper work practices, which include frequent and repeated glove disinfection using sterile 70% IPA during actual compounding of CSPs. All personnel shall demonstrate competency in proper hand hygiene and garbing procedures and in aseptic work practices (e.g., disinfection of component surfaces, routine disinfection of gloved hands).

Sterile contact agar plates shall be used to sample the gloved fingertips of compounding personnel after garbing in order to assess garbing competency and after completing the media-fill preparation (without applying sterile 70% IPA) in order to assess the adequacy of aseptic work practices prior to being initially allowed to prepare CSPs for human use and for more experienced personnel to maintain their qualifications to prepare CSPs for human use.

**Garbing And Gloving Competency Evaluation**— Compounding personnel shall be visually observed during the process of performing hand hygiene and garbing procedures (see Personnel Cleansing and Garbing under Personnel Training and Evaluation in Aseptic Manipulation Skills above). The visual observation shall be documented on a form such as the Sample Form for Assessing Hand Hygiene and Garbing Related Practices of Compounding Personnel (see Appendix III) and maintained to provide a permanent record and long-term assessment of personnel competency.

**Gloved Fingertip Sampling**— All compounding personnel shall successfully complete an initial competency evaluation and gloved fingertip/thumb sampling procedure (zero cfu) no less than three times before initially being allowed to compound CSPs for human use. Immediately after the compounding employee completes the hand hygiene and garbing procedure (e.g., donning of sterile gloves prior to any disinfection with sterile 70% IPA), the evaluator will collect a gloved fingertip and thumb sample from both hands of the compounding employee onto appropriate agar plates by lightly pressing each fingertip into the agar. The plates will be incubated for the appropriate incubation period and at the appropriate temperature (see Incubation Period). After completing the initial gowning and gloving competency evaluation, re-evaluation of all compounding personnel for this competency shall occur at least annually for personnel who compound low- and medium-risk level CSPs and semi-annually for personnel who compound high-risk level CSPs using one or more sample collections during any media-fill test procedure before they are allowed to continue compounding CSPs for human use.

Immediately prior to sampling, gloves shall not be disinfected with sterile 70% IPA. Disinfecting gloves immediately before sampling will provide false negative results. Plates filled with nutrient agar with neutralizing agents such as lecithin and polysorbate 80 added shall be used when sampling personnel fingertips. Personnel shall “touch” the agar with the fingertips of both hands in separate plates in a manner to create a slight impression in the agar. The sampled gloves shall be immediately discarded and proper hand hygiene performed after sampling. The nutrient agar plates shall be incubated as stated below (see Incubation Period). Results should be reported separately as number of cfu per employee per hand (left hand, right hand). The cfu action level for gloved hands will be based on the total number of cfu on both gloves, not per hand.

**Incubation Period**— At the end of the designated sampling period for compounding personnel competency assessment activities (surface or personnel), the agar plates are recovered and covers secured and they are inverted and incubated at a temperature and for a time period conducive to multiplication of microorganisms. TSA with lecithin and polysorbate 80 shall be incubated at 30° to 35° for 48 to 72 hours.

**Aseptic Manipulation Competency Evaluation**— After successful completion of an initial Hand Hygiene and Garbing Competency Evaluation, all compounding personnel shall have their aseptic technique and related practice competency evaluated initially during the Media-Fill Test Procedure and subsequent annual or semi-annual Media-Fill Test Procedures. Records of these evaluations will be maintained using a form such as the Sample Form for Assessing Aseptic Technique and Related Practices of Compounding Personnel (see Appendix IV) and maintained to provide a permanent record of and long-term assessment of personnel competency.

**Media-Fill Test Procedure**— The skill of personnel to aseptically prepare CSPs shall be evaluated using sterile fluid bacterial culture media-fill verification, (i.e., sterile bacterial culture medium transfer via a sterile syringe and needle). Media-fill testing is used to assess the quality of the aseptic skill of compounding personnel. Media-fill tests shall represent the most challenging or stressful conditions actually encountered by the personnel being evaluated when they prepare low- and medium-risk level CSPs and when sterilizing high-risk level CSPs. Media-fill challenge tests are also used to verify the capability of the compounding environment and processes to produce sterile preparations.

A commercially available sterile fluid culture media, such as Soybean-Casein Digest Medium (see [Sterility Tests \(71\)](#)), that is able to promote exponential colonization of bacteria that are most likely to be transmitted to CSPs from the compounding personnel and environment is commonly used. For high-risk level CSPs nonsterile commercially available Soybean-Casein Digest Medium may be used to make a 3% solution. Normal processing steps, including filter sterilization, shall be mimicked. Media-filled vials shall be incubated at 20° to 25° or at 30° to 35° for a minimum of 14 days. If two temperatures are used for incubation of media-filled samples, then these filled containers should be incubated for at least 7 days at each temperature (see [Microbiological Evaluation of Clean Rooms and Other Controlled Environments \(1116\)](#)). Failure is indicated by visible turbidity in any one of the media-fill units on or before 14 days. Other methodologies recommended by a competent microbiologist to enhance recovery time and sensitivity to detect microbial contamination may be considered (see CSP Microbial Contamination Risk Levels for examples of media-fill procedures).

#### surface cleaning and disinfection sampling and assessment

Surface sampling is an important component of the maintenance of a suitable microbially controlled environment for compounding CSPs, especially since transfer of microbial contamination from improperly disinfected work surfaces via inadvertent touch contact by compounding personnel can be a potential source of contamination into CSPs. It is useful for evaluating facility and work surface cleaning and disinfecting procedures and employee competency in work practices such as disinfection of component/vial surface cleaning. Surface sampling shall be performed in all ISO classified areas on a periodic basis. Sampling can be accomplished using contact plates or swabs, and it shall be done at the conclusion of compounding. Locations to be sampled shall be defined in a sample plan or on a form. The size of the plate to be used for each sampled location usually ranges from 24 to 30 cm<sup>2</sup>. Contact plates are filled with general solid agar growth medium and neutralizing agents above the rim of the plate, and they are used for sampling regular or flat surfaces. Swabs may be used for sampling irregular surfaces, especially for equipment (see [Microbiological Evaluation of Clean Rooms and Other Controlled Environments \(1116\)](#)).

**Cleaning and Disinfecting Competency Evaluation**— Compounding personnel and other personnel responsible for cleaning shall be visually observed during the process of performing cleaning and disinfecting procedures, during initial personnel training on cleaning procedures, during changes in cleaning staff, and at the completion of any media-fill test procedure (see Cleaning and Disinfecting of Compounding Areas).

The visual observation shall be documented using a form such as the Sample Form for Assessing Cleaning and Disinfection Procedures (see Appendix V) and maintained to provide a permanent record and long-term assessment of personnel competency.

**Surface Collection Methods**— To sample surfaces using a contact plate, gently touch the sample area with the agar surface and roll the plate across the surface to be sampled. The contact plate will leave a growth media residue behind; therefore, immediately after sampling with the contact plate, the sampled area shall be thoroughly wiped with a nonshedding wipe soaked in sterile 70% IPA.

If an area is sampled via the swab method, collection of the sample is processed by using appropriate procedures that will result in the surface location equivalent to that of a contact plate. After swabbing the surface to be sampled, swabs are placed in an appropriate diluent; an aliquot is plated on or in the specified nutrient agar. Results should be reported as cfu per unit of surface area.

#### Action Levels, Documentation, and Data Evaluation

The value of viable microbial monitoring of gloved fingertips and surfaces of components and the compounding environment are realized when the data are used to identify and correct an unacceptable work practice. Sampling data shall be collected and reviewed on a routine basis as a means of evaluating the overall control of the compounding environment. If an activity consistently shows elevated levels of microbial growth, competent microbiology personnel shall be consulted.

Any cfu count that exceeds its respective action level (see [Table 4](#)) should prompt a re-evaluation of the adequacy of personnel work practices, cleaning procedures, operational procedures, and air filtration efficiency within the aseptic compounding location. An investigation into the source of the contamination shall be conducted. Sources could include HVAC systems, damaged HEPA filters, and changes in personnel garbing or working practices. The source of the problem shall be eliminated, the affected area cleaned, and resampling performed.

When gloved fingertip sample results exceed action levels after proper incubation, a review of hand hygiene and garbing procedures as well as glove and surface disinfection procedures and work practices shall be performed and documented. Employee training may be required to correct the source of the problem.

Counts of cfu are to be used as an approximate measure of the environmental microbial bioburden. Action levels are determined on the basis of cfu data gathered at each sampling location and trended over time. The numbers in [Table 4](#) should be used only as guidelines. Regardless of the number of cfu identified in the compounding facility, further corrective actions will be dictated by the identification of microorganisms recovered (at least the genus level) by an appropriate credentialed laboratory of any microbial bioburden captured as a cfu using an impaction air sampler. Highly pathogenic microorganisms (e.g., Gram-negative rods, coagulase positive staphylococcus, molds and yeasts) can be potentially fatal to patients receiving CSPs and shall be immediately remedied, regardless of cfu count, with the assistance of a competent microbiologist, infection control professional, or industrial hygienist.

Table 4. Recommended Action Levels for Microbial Contamination\*

Classification	Fingertip Sample	Surface Sample (Contact Plate) (cfu per plate)
ISO Class 5	> 3	> 3
ISO Class 7	N/A	> 5
ISO Class 8 or worse	N/A	> 100

\* Pharmaceutical Inspection Co-operation Scheme (PIC/S) Guide to Good Manufacturing Practice for Medicinal Products Annexes PE 009-6, 5 April 2007.

#### SUGGESTED STANDARD OPERATING PROCEDURES (SOPs)

The compounding facility shall have written, properly approved SOPs designed to ensure the quality of the environment in which a CSP is prepared. The following procedures are recommended:

1. Access to the buffer area is restricted to qualified personnel with specific responsibilities or assigned tasks in the compounding area.
2. All cartoned supplies are decontaminated in the area by removing them from shipping cartons and wiping or spraying them with a nonresidue-generating disinfecting agent while they are being transferred to a clean and properly disinfected cart or other conveyance for introduction into the buffer area. Manufacturers' directions or published data for minimum contact time will be followed. Individual pouched sterile supplies need not be wiped because the pouches can be removed as these sterile supplies are introduced into the buffer area.
3. Supplies that are required frequently or otherwise needed close at hand but not necessarily needed for the scheduled operations of the shift are decontaminated and stored on shelving in the ante-area.
4. Carts used to bring supplies from the storeroom cannot be rolled beyond the demarcation line in the ante-area, and carts used in the buffer area cannot be rolled outward beyond the demarcation line unless cleaned and disinfected before returning.
5. Generally, supplies required for the scheduled operations of the shift are wiped down with an appropriate disinfecting agent and brought into the buffer area, preferably on one or more movable carts. Supplies that are required for back-up or general support of operations may be stored on the designated shelving in the buffer area, but excessive amounts of supplies are to be avoided.
6. Nonessential objects that shed particles shall not be brought into the buffer area, including pencils, cardboard cartons, paper towels, and cotton items (e.g., gauze pads).
7. Essential paper-related products (e.g., paper syringe overwraps, work records contained in a protective sleeve) shall be wiped down with an appropriate disinfecting agent prior to being brought into the buffer area.
8. Traffic flow in and out of the buffer area shall be minimized.
9. Personnel preparing to enter the buffer area shall remove all personal outer garments, cosmetics (because they shed flakes and particles), and all hand, wrist, and other visible jewelry or piercings that can interfere with the effectiveness of PPE.
10. Personnel entering the ante-area shall don attire as described in Personnel Cleansing and Garbing and Personnel Training and Competency Evaluation of Garbing, Aseptic Work Practices and Cleaning/Disinfection Procedures.
11. Personnel shall then thoroughly wash hands and forearms to the elbow with soap and water for at least 30 seconds. An air dryer or disposable nonshedding towels are used to dry hands and forearms after washing.
12. Personnel entering the buffer area shall perform antiseptic hand cleansing prior to donning sterile gloves using a waterless alcohol-based surgical hand scrub with persistent activity.
13. Chewing gum, drinks, candy, or food items shall not be brought into the buffer area or ante-area. Materials exposed in patient care and treatment areas shall never be introduced into areas where components and ingredients for CSPs are present.
14. At the beginning of each compounding activity session, and whenever liquids are spilled, the surfaces of the direct compounding environment are first cleaned with USP Purified Water to remove water-soluble residues. Immediately thereafter, the same surfaces are disinfected with a nonresidue-generating agent using a nonlinting wipe.
15. Primary engineering controls shall be operated continuously during compounding activity. When the blower is turned off and before other personnel enter to perform compounding activities, only one person shall enter the buffer area for the purposes of turning on the blower (for at least 30 minutes) and disinfecting the work surfaces.
16. Traffic in the area of the DCA is minimized and controlled.
17. Supplies used in the DCA for the planned procedures are accumulated and then decontaminated by wiping or spraying the outer surface with sterile 70% IPA or removing the outer wrap at the edge of the DCA as the item is introduced into the aseptic work area.
18. All supply items are arranged in the DCA so as to reduce clutter and provide maximum efficiency and order for the flow of work.
19. After proper introduction into the DCA of supply items required for and limited to the assigned operations, they are so arranged that a clear, uninterrupted path of HEPA-filtered air will bathe all critical sites at all times during the planned procedures. That is, no objects may be placed between the first air from HEPA filters and an exposed critical site.
20. All procedures are performed in a manner designed to minimize the risk of touch contamination. Gloves are disinfected with adequate frequency with an approved disinfectant such as sterile 70% IPA.
21. All rubber stoppers of vials and bottles and the necks of ampuls are disinfected by wiping with sterile 70% IPA and waiting for at least 10 seconds before they are used to prepare CSPs.
22. After the preparation of every CSP, the contents of the container are thoroughly mixed and then inspected for the presence of particulate matter, evidence of incompatibility, or other defects.
23. After procedures are completed, used syringes, bottles, vials, and other supplies are removed, but with a minimum of exit and re-entry into the DCA so as to minimize the risk of introducing contamination into the aseptic workspace.

#### ELEMENTS OF QUALITY CONTROL

A written description of specific training and performance evaluation program for individuals involved in the use of aseptic techniques for the preparation of sterile products shall be developed for each site. This program equips personnel with the appropriate knowledge and trains them in the required skills necessary to perform the assigned tasks. Each person assigned to the aseptic area in the preparation of sterile products shall successfully complete specialized training in aseptic techniques and aseptic area practices prior to preparing CSPs (see Personnel Training and Evaluation in Aseptic Manipulation Skills and Personnel Training and Competency Evaluation of Garbing, Aseptic Work Practices and

Cleaning/Disinfection Procedures).

#### Ingredients and Devices

Compounding personnel ascertain that ingredients for CSPs are of the correct identity and appropriate quality using the following information: vendor labels, labeling, certificates of analysis, direct chemical analysis, and knowledge of compounding facility storage conditions.

##### sterile ingredients and devices

Commercially available sterile drug products, sterile ready-to-use containers, and devices are examples of sterile components. A written procedure for unit-by-unit physical inspection preparatory to use is followed to ensure that these components are sterile, free from defects, and otherwise suitable for their intended use.

##### nonsterile ingredients and devices

If any nonsterile components, including containers and ingredients, are used to make a CSP, such CSPs must be high risk. Nonsterile active ingredients and added substances or excipients for CSPs should preferably be official USP or NF articles. When nonofficial ingredients are used, they shall be accompanied by certificates of analysis from their suppliers to aid compounding personnel in judging the identity, quality, and purity in relation to the intended use in a particular CSP. Physical inspection of a package of ingredients is necessary in order to detect breaks in the container, looseness in the cap or closure, and deviation from the expected appearance, aroma, and texture of the contents.

Bulk or unformulated drug substances and added substances or excipients shall be stored in tightly closed containers under temperature, humidity, and lighting conditions that are either indicated in official monographs or approved by suppliers. The date of receipt by the compounding facility shall be clearly and indelibly marked on each package of ingredient.

After receipt by the compounding facility, packages of ingredients that lack a supplier's expiration date cannot be used after 1 year unless either appropriate inspection or testing indicates that the ingredient has retained its purity and quality for use in CSPs.

Careful consideration and evaluation of nonsterile ingredient sources is especially warranted when the CSP will be administered into the vascular system, central nervous system, or eyes.

Upon receipt of each lot of the bulk drug substance or excipient used for CSPs, the individual compounding the preparation performs a visual inspection of the lot for evidence of deterioration, other types of unacceptable quality, and wrong identification. For bulk drug substances or excipients, visual inspection is performed on a routine basis as described in the written protocol.

#### Equipment

It is necessary that equipment, apparatus, and devices used to compound a CSP be consistently capable of operating properly and within acceptable tolerance limits. Written procedures outlining required equipment calibration, annual maintenance, monitoring for proper function, and controlled procedures for use of the equipment and specified time frames for these activities are established and followed. Routine maintenance and frequencies shall be outlined in these SOPs. Results from the equipment calibration, annual maintenance reports, and routine maintenance are kept on file for the lifetime of the equipment. Personnel are prepared through an appropriate combination of specific training and experience to operate or manipulate any piece of equipment, apparatus, or device they may use when preparing CSPs. Training includes gaining the ability to determine whether any item of equipment is operating properly or is malfunctioning.

#### VERIFICATION OF AUTOMATED COMPOUNDING DEVICES (ACDs) FOR PARENTERAL NUTRITION COMPOUNDING

ACDs for the preparation of parenteral nutrition admixtures are widely used by pharmacists in hospitals and other healthcare settings. They are designed to streamline the labor-intensive processes involved in the compounding of these multiple-component formulations by automatically delivering the individual nutritional components in a predetermined sequence under computerized control. Parenteral nutrition admixtures often contain 20 or more individual additives representing as many as 50 or more individual components (e.g., 15 to 20 crystalline amino acids, dextrose monohydrate, and lipids; 10 to 12 electrolyte salts; 5 to 7 trace minerals; and 12 vitamins). Thus, ACDs can provide improved accuracy and precision of the compounding process over the traditional manual compounding methods.

#### Accuracy

The accuracy of an ACD can be determined in various ways to ensure that the correct quantities of nutrients, electrolytes, or other nutritional components are delivered to the final infusion container. Initially, the ACD is tested for its volume and weight accuracy. For volume accuracy, a suitable volume of Sterile Water for Injection, USP, which represents a typical additive volume (e.g., 40 mL for small-volume range of 1 to 100 mL, 300 mL for large-volume range of 100 to 1000 mL), is programmed into the ACD and delivered to the appropriate volumetric container. The compounding personnel should then consult [Volumetric Apparatus](#) (31) for appropriate parameters to assess the volumetric performance of the ACD. For gravimetric accuracy, the balance used in conjunction with the ACD is tested using various weight sizes that represent the amounts typically used to deliver the various additives.

Compounding personnel should consult [Weights and Balances](#) (41) for acceptable tolerances of the weights used. In addition, the same volume of [Sterile Water for Injection](#) used to assess volumetric accuracy is then weighed on the balance used in conjunction with the ACD. For example, if 40 mL of water was used in the volumetric assessment, its corresponding weight should be about 40 g (assuming the relative density of water is 1.0). In addition, during the use of the ACD, certain additives, such as potassium chloride (corrected for density differences), can also be tested in the same manner as with an in-process test.

Finally, additional tests of accuracy may be employed that determine the content of certain ingredients in the final volume of the parenteral nutrition admixture. Generally, pharmacy departments do not have the capability to routinely perform chemical analyses such as analyses of dextrose or electrolyte concentrations. Consequently, hospital or institutional laboratories may be called upon to perform these quality assurance tests. However, the methods in such laboratories are often designed for biological, not pharmaceutical, systems.

Thus, their testing procedures shall be verified to meet the USP requirements stated in the individual monograph for the component being tested. For example, under [Dextrose Injection](#), the following is stated: It contains not less than 95.0% and not more than 105.0% of the labeled amount of C6H12O6·H2O. The hospital or institutional chemistry laboratories must validate their methods to apply to this range and correct for their typical measurement of anhydrous dextrose versus dextrose monohydrate. Similar ranges and issues exist, for example, for injections of calcium gluconate, magnesium sulfate, and potassium chloride. The critical point is the use of USP references and possible laboratory procedural differences.

#### Precision

The intermediate precision of the ACD can be determined on the basis of the day-to-day variations in performance of the accuracy measures. Thus, compounding personnel shall keep a daily record of the above-described accuracy assessments and review the results over time. This review shall occur at least at weekly intervals to avoid potentially clinically significant cumulative errors over time. This is especially true for additives with a narrow therapeutic index, such as potassium chloride.

#### FINISHED PREPARATION RELEASE CHECKS AND TESTS

The following quality metrics shall be performed for all CSPs before they are dispensed or administered.

##### Inspection of Solution Dosage Forms and Review of Compounding Procedures

All CSPs that are intended to be solutions shall be visually examined for the presence of particulate matter and not administered or dispensed when such matter is observed. The prescription orders, written compounding procedure, preparation records, and expended materials used to make CSPs at all contamination risk levels are inspected for accuracy of correct identities and amounts of ingredients, aseptic mixing and sterilization, packaging, labeling, and expected physical appearance before they are administered or dispensed.

##### physical inspection

Finished CSPs are individually inspected in accordance with written procedures after compounding. If not distributed promptly, these CSPs are individually inspected just prior to leaving the storage area. Those CSPs that are not immediately distributed are stored in an appropriate location as described in the written procedures. Immediately after compounding, and as a condition of release, each CSP unit, where possible, should be inspected against lighted white or black background or both for evidence of visible particulates or other foreign matter. Prerelase inspection also includes container-closure integrity and any other apparent visual defect. CSPs with observed defects should be immediately discarded or marked and segregated from acceptable products in a manner that prevents their administration. When CSPs are not distributed promptly after preparation, a predistribution inspection is

conducted to ensure that a CSP with defects, such as precipitation, cloudiness, and leakage, which may develop between the time of release and the time of distribution, is not released.

#### Compounding Accuracy Checks

Written procedures for double-checking compounding accuracy shall be followed for every CSP during preparation and immediately prior to release. The double-check system should meet state regulations and include label accuracy and accuracy of the addition of all drug products or ingredients used to prepare the finished product and their volumes or quantities. The used additive containers and, for those additives for which the entire container was not expended, the syringes used to measure the additive should be quarantined with the final products until the final product check is completed. Compounding personnel shall visually confirm that ingredients measured in syringes match the written order being compounded. Preferably, a person other than the compounder can verify that correct volumes of correct ingredients were measured to make each CSP. For example, compounding personnel would pull the syringe plunger back to the volume measured.

When practical, the accuracy of measurements is confirmed by weighing a volume of the measured fluid, then calculating that volume by dividing the weight by the accurate value of the density, or specific gravity, of the measured fluid. Correct density or specific gravity values programmed in ACDs, which measure by weight using the quotient of the programmed volume divided by the density or specific gravity, shall be confirmed to be accurate before and after delivering volumes of the liquids assigned to each channel or port. These volume accuracy checks and the following additional safety and accuracy checks in this section shall be included in the SOP manual of the CSP facility.

#### Sterility Testing

All high-risk level CSPs that are prepared in groups of more than 25 identical individual single-dose packages (e.g., ampuls, bags, syringes, vials) or in multiple-dose vials (MDVs) for administration to multiple patients or that are exposed longer than 12 hours at 2° to 8° and longer than 6 hours at warmer than 8° before they are sterilized shall meet the sterility test (see [Sterility Tests \(71\)](#)) before they are dispensed or administered. The Membrane Filtration method is the method of choice where feasible (e.g., components are compatible with the membrane). A method not described in the USP may be used if verification results demonstrate that the alternative is at least as effective and reliable as the USP Membrane

Filtration method or the USP Direct Inoculation of the Culture Medium method where the Membrane Filtration method is not feasible.

When high-risk level CSPs are dispensed before receiving the results of their sterility tests, there shall be a written procedure requiring daily observation of the incubating test specimens and immediate recall of the dispensed CSPs when there is any evidence of microbial growth in the test specimens. In addition, the patient and the physician of the patient to whom a potentially contaminated CSP was administered are notified of the potential risk. Positive sterility test results should prompt a rapid and systematic investigation of aseptic technique, environmental control, and other sterility assurance controls to identify sources of contamination and correct problems in the methods or processes.

#### Bacterial Endotoxin (Pyrogen) Testing

All high-risk level CSPs, except those for inhalation and ophthalmic administration, that are prepared in groups of more than 25 identical individual single-dose packages (e.g., ampuls, bags, syringes, vials) or in MDVs for administration to multiple patients or that are exposed longer than 12 hours at 2° to 8° and longer than 6 hours at warmer than 8° before they are sterilized shall be tested to ensure that they do not contain excessive bacterial endotoxins (see [Bacterial Endotoxins Test \(85\)](#) and [Pyrogen Test \(151\)](#)). In the absence of a bacterial endotoxins limit in the official monograph or other CSP formula source, the CSP shall not exceed the amount of USP Endotoxin Units (per hour per kilogram of body weight or square meters of body surface area) specified in [Bacterial Endotoxins Test \(85\)](#) referenced above for the appropriate route of administration.

#### Identity and Strength Verification of Ingredients

Compounding facilities shall have at least the following written procedures for verifying the correct identity and quality of CSPs before they are dispensed and administered:

1. That labels of CSPs bear correct names and amounts or concentrations of ingredients, the total volume, the BUD, the appropriate route(s) of administration, the storage conditions, and other information for safe use.
2. That there are correct identities, purities, and amounts of ingredients by comparing the original written order with the written compounding record for the CSP.
3. That correct fill volumes in CSPs and correct quantities of filled units of the CSPs were obtained. When the strength of finished CSPs cannot be confirmed to be accurate, based on the above three inspections, the CSPs shall be assayed by methods that are specific for the active ingredients.

#### STORAGE AND BEYOND-USE DATING

BUDs for compounded preparations are usually assigned on the basis of professional experience, which should include careful interpretation of appropriate information sources for the same or similar formulations (see Stability Criteria and Beyond-Use Dating under [Pharmaceutical Compounding—Nonsterile Preparations \(795\)](#)). BUDs for CSPs are rarely based on preparation-specific chemical assay results, which are used with the Arrhenius equation to determine expiration dates (see General Notices and Requirements) for manufactured products. The majority of CSPs are aqueous solutions in which hydrolysis of dissolved ingredients is the most common chemical degradation reaction. The extent of hydrolysis and other heat-catalyzed degradation reactions at any particular time point in the life of a CSP represents the thermodynamic sum of exposure temperatures and durations. Such lifetime stability exposure is represented in the mean kinetic temperature calculation (see [Pharmaceutical Calculations in Prescription Compounding \(1160\)](#)). Drug hydrolysis rates increase exponentially with arithmetic temperature increase; thus, exposure of a beta-lactam antibiotic solution for 1 day at controlled room temperature (see General Notices and Requirements) will have an equivalent effect on the extent of hydrolysis of approximately 3 to 5 days in cold temperatures (see General Notices and Requirements).

Personnel who prepare, dispense, and administer CSPs shall store them strictly in accordance with the conditions stated on the label of ingredient products and finished CSPs. When CSPs are known to have been exposed to temperatures warmer than the warmest labeled limit or to temperatures exceeding 40° (see General Notices and Requirements) for more than 4 hours, such CSPs should be discarded unless direct assay data or appropriate documentation confirms their continued stability.

#### Determining Beyond-Use Dates

BUDs and expiration dates are not the same (see General Notices and Requirements). Expiration dates for the chemical and physical stability of manufactured sterile products are determined from results of rigorous analytical and performance testing, and they are specific for a particular formulation in its container and at stated exposure conditions of illumination and temperature. When CSPs deviate from conditions in the approved labeling of manufactured products contained in CSPs, compounding personnel may consult the manufacturer of particular products for advice on assigning BUDs based on chemical and physical stability parameters. BUDs for CSPs that are prepared strictly in accordance with manufacturers' product labeling shall be those specified in that labeling or from appropriate literature sources or direct testing. BUDs for CSPs that lack justification from either appropriate literature sources or by direct testing evidence shall be assigned as described in Stability Criteria and Beyond-Use Dating under [Pharmaceutical Compounding—Nonsterile Preparations \(795\)](#).

In addition, compounding personnel may refer to applicable publications to obtain relevant stability, compatibility, and degradation information regarding the drug or its congeners. When assigning a beyond-use date, compounding personnel should consult and apply drug-specific and general stability documentation and literature where available, and they should consider the nature of the drug and its degradation mechanism, the container in which it is packaged, the expected storage conditions, and the intended duration of therapy (see [Expiration Date and Beyond-Use Date under Labeling in the General Notices and Requirements](#)). Stability information must be carefully interpreted in relation to the actual compounded formulation and conditions for storage and use. Predictions based on other evidence, such as publications, charts, and tables, would result in theoretical BUDs. Theoretically predicted beyond-use dating introduces varying degrees of assumptions and, hence, a likelihood of error or at least inaccuracy. The degree of error or inaccuracy would be dependent on the extent of differences between the CSPs' characteristics (e.g., composition, concentration of ingredients, fill volume, container type and material) and the characteristics of the products from which stability data or information is to be extrapolated. The greater the doubt of the accuracy of theoretically predicted beyond-use dating, the greater the need to determine dating periods experimentally. Theoretically predicted beyond-use dating periods should be carefully considered for CSPs prepared from nonsterile bulk active ingredients having therapeutic activity, especially where these CSPs are expected to be compounded routinely. When CSPs will be distributed to and administered in residential locations other than healthcare facilities, the effect of potentially uncontrolled and unmonitored temperature conditions shall be considered when assigning BUDs. It must be ascertained that CSPs will not be exposed to warm temperatures (see General Notices and Requirements) unless the compounding facility has evidence to justify stability of CSPs during such exposure.

It should be recognized that the truly valid evidence of stability for predicting beyond-use dating can be obtained only through product-specific experimental studies. Semiquantitative procedures such as thin-layer chromatography (TLC) may be acceptable for many CSPs. However, quantitative stability-indicating assays such as high-performance liquid chromatographic (HPLC) assays would be more appropriate for certain CSPs. Examples include CSPs with a narrow therapeutic index, where close monitoring or dose titration is required to ensure therapeutic effectiveness and to avoid toxicity; where a theoretically established beyond-use dating period is supported by only marginal evidence; or where a significant margin of safety cannot be verified for the proposed beyond-use dating period. In short, because beyond-use dating periods established from product-specific data acquired from the appropriate instrumental analyses are clearly more reliable than those predicted theoretically, the former approach is strongly urged to support dating periods exceeding 30 days.

To ensure consistent practices in determining and assigning BUDs, the compounding facility should have written policies and procedures governing the determination of the BUDs for all compounded products. When attempting to predict a theoretical BUD, a compounded or an admixed preparation should be considered as a unique system that has physical and chemical properties and stability characteristics that differ from its components. For example, antioxidant, buffering, or antimicrobial properties of a sterile vial for injection (SVI) might be lost upon its dilution, with the potential of seriously compromising the chemical stability of the SVI's active ingredient or the physical or microbiological stability of the SVI formulation in general. Thus, the properties stabilized in the SVI formulation usually cannot be expected to be carried over to the compounded or admixed preparation. Preparation-specific, experimentally determined stability data evaluation protocols are preferable to published stability information. Compounding personnel should consult general information chapter [Pharmaceutical Stability](#) (1150) for the appropriate stability parameters to be considered when initiating or evaluating a preparation-specific stability study.

Compounding personnel who assign BUDs to CSPs when lacking direct chemical assay results must critically interpret and evaluate the most appropriate available information sources to determine a conservative and safe BUD. The SOP manual of the compounding facility and each specific CSP formula record shall describe the general basis used to assign the BUD and storage conditions.

When manufactured MDVs (see Multiple-Dose Container under Preservation, Packaging, Storage, and Labeling in the General Notices and Requirements) of sterile ingredients are used in CSPs, the stoppers of the MDVs are inspected for physical integrity and disinfected by wiping with a sterile 70% IPA swab before each penetration with a sterile withdrawal device. When contaminants or abnormal properties are suspected or observed in MDVs, such MDVs shall be discarded. The BUD after initially entering or opening (e.g., needle puncturing) multiple-dose containers is 28 days (see [Antimicrobial Effectiveness Testing](#) (51)) unless otherwise specified by the manufacturer.

#### Proprietary Bag and Vial Systems

The sterility storage and stability beyond-use times for attached and activated (where activated is defined as allowing contact of the previously separate diluent and drug contents) container pairs of drug products for intravascular administration (e.g., ADD-Vantage®, Mini Bag Plus®) shall be applied as indicated by the manufacturer. In other words, follow manufacturers' instructions for handling and storing ADD-Vantage®, Mini Bag Plus®, Add A Vial®, Add-Ease® products, and any others.

#### Monitoring Controlled Storage Areas

To ensure that product potency is retained through the manufacturer's labeled expiration date, compounding personnel shall monitor the drug storage areas within the compounding facility. Controlled temperature areas in compounding facilities include controlled room temperature, 20° to 25° with mean kinetic temperature 25°; controlled cold temperature, 2° to 8° with mean kinetic temperature 8°; cold temperature, 2° to 8°; freezing temperature, -25° and -10° (see General Notices and Requirements) if needed to achieve freezing, and the media-specific temperature range for microbial culture media. A controlled temperature area shall be monitored at least once daily and the results documented on a temperature log.

Additionally, compounding personnel shall note the storage temperature when placing the product into or removing the product from the storage unit in order to monitor any temperature aberrations. Suitable temperature recording devices may include a calibrated continuous recording device or a National Institute of Standards and Technology (NIST) calibrated thermometer that has adequate accuracy and sensitivity for the intended purpose, and it shall be properly calibrated at suitable intervals. If the compounding facility uses a continuous temperature recording device, compounding personnel shall verify at least once daily that the recording device itself is functioning properly.

The temperature-sensing mechanisms shall be suitably placed in the controlled temperature storage space to reflect accurately its true temperature. In addition, the compounding facility shall adhere to appropriate procedures of all controlled storage spaces to ensure that such spaces are not subject to significantly prolonged temperature fluctuations as may occur, for example, by leaving a refrigerator door open too long.

#### MAINTAINING STERILITY, PURITY, AND STABILITY OF DISPENSED AND DISTRIBUTED CSPs

This section summarizes the responsibilities of compounding facilities for maintaining quality and control of CSPs that are dispensed and administered within their parent healthcare organizations.

Compounding personnel shall ensure proper storage and security of CSPs prepared by or dispensed from the compounding facility until either their BUDs are reached or they are administered to patients. In fulfilling this general responsibility, the compounding facility is responsible for the proper packaging, handling, transport, and storage of CSPs prepared by or dispensed from it, including the appropriate education, training, and supervision of compounding personnel assigned to these functions. The compounding facility should assist in the education and training of noncompounding personnel responsible for carrying out any aspect of these functions.

Establishing, maintaining, and ensuring compliance with comprehensive written policies and procedures encompassing these responsibilities is a further responsibility of the compounding facility. Where noncompounding personnel are assigned tasks involving any of these responsibilities, the policies and procedures encompassing those tasks should be developed by compounding supervisors. The quality and control activities related to distribution of CSPs are summarized in the following five subsections. Activities or concerns that should be addressed as the compounding facility fulfills these responsibilities are as follows.

#### Packaging, Handling, and Transport

Inappropriate processes or techniques involved with packaging, handling, and transport can adversely affect quality and package integrity of CSPs. Although compounding personnel routinely perform many of the tasks associated with these functions, some tasks, such as transport, handling, and placement into storage, may be fulfilled by noncompounding personnel who are not under the direct administrative control of the compounding facility. Under these circumstances, appropriate SOPs shall be established by the compounding facility with the involvement of other departments or services whose personnel are responsible for carrying out those CSP-related functions for which the compounding facility has a direct interest. The performance of the noncompounding personnel is monitored for compliance to established policies and procedures.

The critical requirements that are unique to CSPs and that are necessary to ensure CSP quality and packaging integrity shall be addressed in SOPs. For example, techniques should be specified to prevent the depression of syringe plungers or dislodging of syringe tips during handling and transport. Additionally, disconnection of system components (e.g., where CSPs are dispensed with administration sets attached to them) shall be prevented through the BUD of the CSP. Foam padding or inserts are particularly useful where CSPs are transported by pneumatic tube systems. Regardless of the methods used, the compounding facility must evaluate their effectiveness and the reliability of the intended protection.

Evaluation should be continuous—for example, through a surveillance system, including a system of problem reporting to the compounding facility.

Inappropriate transport and handling can adversely affect the quality of certain CSPs having unique stability concerns. For example, the physical shaking that might occur during pneumatic tube transport or undue exposure to heat or light must be addressed on a preparation-specific basis. Alternative transport modes or special packaging measures might be needed for the proper assurance of quality of these CSPs. The use of tamper-evident closures and seals on CSP ports can add an additional measure of security to ensure product integrity regardless of the transport method used.

Chemotoxic and other hazardous CSPs require safeguards to maintain the integrity of the CSP and to minimize the exposure potential of these products to the environment and to personnel who may come in contact with them. Transportation by pneumatic tube should be discouraged because of potential breakage and contamination. Special requirements associated with the packaging, transport, and handling of these agents include the prevention of accidental exposures or spills and the training of personnel in the event of an exposure or spill. Examples of special requirements of these agents also include exposure-reducing strategies such as the use of Luer lock syringes and connections, syringe caps, the capping of container ports, sealed plastic bags, impact-resistant containers, and cautionary labeling.

#### Use and Storage

The compounding facility is responsible for ensuring that CSPs in the patient-care setting maintain their quality until administered. The immediate labeling of the CSP container will display prominently and understandably the requirements for proper storage and expiration dating. Delivery and patient-care-setting personnel shall be properly trained to deliver the CSP to the appropriate storage location. Outdated and unused CSPs shall be returned to the compounding facility for disposition.
